About this Book and the Library

The NetIQ Reference Guide product (AppManager) is a comprehensive solution for managing, diagnosing, and analyzing performance, availability, and health for a broad spectrum of operating environments, applications, services, and server hardware.

Reference Guide provides system administrators with a central, easy-to-use console to view critical server and application resources across the enterprise. With Reference Guide, administrative staff can monitor computer and application resources, check for potential problems, initiate responsive actions, automate routine tasks, and gather performance data for real-time and historical reporting and analysis.

Intended Audience

This guide provides information for individuals responsible for installing an AppManager module and monitoring specific applications with AppManager.

Other Information in the Library

The library provides the following information resources:

Installation Guide for AppManager

Provides complete information about AppManager pre-installation requirements and step-by-step installation procedures for all AppManager components.

User Guide for AppManager Control Center

Provides complete information about managing groups of computers, including running jobs, responding to events, creating reports, and working with Control Center. A separate guide is available for the AppManager Operator Console.

Administrator Guide for AppManager

Provides information about maintaining an AppManager management site, managing security, using scripts to handle AppManager tasks, and leveraging advanced configuration options.

Upgrade and Migration Guide for AppManager

Provides complete information about how to upgrade from a previous version of AppManager.

Management guides

Provide information about installing and monitoring specific applications with AppManager.

Help

Provides context-sensitive information and step-by-step guidance for common tasks, as well as definitions for each field on each window.

The Reference Guide library is available in Adobe Acrobat (PDF) format from the AppManager Documentation page of the NetIQ website.

About NetIQ Corporation

We are a global, enterprise software company, with a focus on the three persistent challenges in your environment: Change, complexity and risk—and how we can help you control them.

Our Viewpoint

Adapting to change and managing complexity and risk are nothing new

In fact, of all the challenges you face, these are perhaps the most prominent variables that deny you the control you need to securely measure, monitor, and manage your physical, virtual, and cloud computing environments.

Enabling critical business services, better and faster

We believe that providing as much control as possible to IT organizations is the only way to enable timelier and cost effective delivery of services. Persistent pressures like change and complexity will only continue to increase as organizations continue to change and the technologies needed to manage them become inherently more complex.

Our Philosophy

Selling intelligent solutions, not just software

In order to provide reliable control, we first make sure we understand the real-world scenarios in which IT organizations like yours operate — day in and day out. That's the only way we can develop practical, intelligent IT solutions that successfully yield proven, measurable results. And that's so much more rewarding than simply selling software.

Driving your success is our passion

We place your success at the heart of how we do business. From product inception to deployment, we understand that you need IT solutions that work well and integrate seamlessly with your existing investments; you need ongoing support and training post-deployment; and you need someone that is truly easy to work with — for a change. Ultimately, when you succeed, we all succeed.

Our Solutions

- Identity & Access Governance
- Access Management
- Security Management
- Systems & Application Management
- Workload Management
- Service Management

Contacting Sales Support

For questions about products, pricing, and capabilities, contact your local partner. If you cannot contact your partner, contact our Sales Support team.

Contacting Documentation Support

Our goal is to provide documentation that meets your needs. The documentation for this product is available on the NetIQ website in HTML and PDF formats on a page that does not require you to log in. If you have suggestions for documentation improvements, click **comment on this topic** at the bottom of any page in the HTML version of the documentation posted at www.netiq.com/documentation. You can also email Documentation-Feedback@netiq.com. We value your input and look forward to hearing from you.

Contacting the Online User Community

NetIQ Communities, the NetIQ online community, is a collaborative network connecting you to your peers and NetIQ experts. By providing more immediate information, useful links to helpful resources, and access to NetIQ experts, NetIQ Communities helps ensure you are mastering the knowledge you need to realize the full potential of IT investments upon which you rely. For more information, visit community.netiq.com.

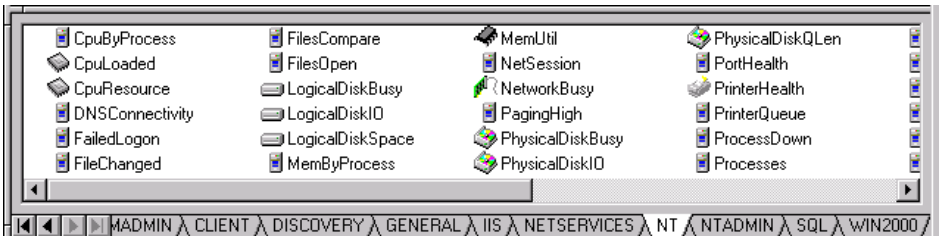
1 Introduction to Knowledge Scripts

This topic provides an introduction to the Knowledge Scripts available in the NetIQ AppManager product and a brief review of how Knowledge Scripts are used to set up and run monitoring jobs. It also includes information about special privileges that are required to run some Knowledge Scripts.

1.1 Introduction to Knowledge Script Categories

Knowledge Scripts are grouped into categories and displayed under different tabs in the Knowledge Script pane in the Operator Console. Some Knowledge Script categories — such as AMAdmin, Discovery, General, and Action — are available to all users. The availability of additional Knowledge Scripts categories depends on the servers you are managing and the AppManager modules you have purchased and installed. For example, if you have licensed and installed AppManager for Microsoft Exchange 2007, and AppManager for Microsoft SQL Server, the Knowledge Script pane includes tabs for these Knowledge Script categories.

A typical set of the Knowledge Script categories for most users looks similar to this:



1.2 Understanding Resource Types and Type Checking

Each Knowledge Script is associated with one or more **resource object types**. The type determines which resource objects the Knowledge Script can be applied to. For example, it does not make sense to run a Knowledge Script that monitors Exchange mail on a SQL Server. Internally, AppManager handles the type checking to ensure that each Knowledge Script runs only on the types of resource objects that it can manage.

1.2.1 Folders and Objects

The resource types shipped with AppManager fall into two categories: **folders** and **objects**.

Folders

Used to group similar objects to simplify viewing. Folders can be opened (expanded) or closed (collapsed) to view the objects contained within them.

Objects

Individual resources that AppManager can monitor, such as disk drives or CPU resources.

As an example, the NT TreeView includes a Logical Disk folder icon. All of the logical disk icons underneath the folder, for example, `C:` or `D:`, represent individual logical disk partitions and are resource objects of the same type.

1.2.2 Icons Displayed for Matching Type

When a Knowledge Script is dragged into the TreeView and an object icon becomes a green dot, it means the Knowledge Script type matches the target object's type. If the icon is displayed with a right arrow, the Knowledge Script type matches the type of at least one of the object's children. If the icon has a left arrow, it means the Knowledge Script type matches the type of at least one of the object's parents.

If any of these icons is displayed, the Knowledge Script has found an appropriate target and can start a job. If a green icon is not displayed, the Knowledge Script does not match the object and the job cannot be started.

If a Knowledge Script is dropped on an appropriate object and an event is detected, the event indicator highlights the specific object icon where the problem was found in the TreeView pane. Any parent objects or folder icons also flash to alert you to the event, all the way to the top of the TreeView. So, even if an object is folded into its parent's icon, an indication of the event is always visible.

1.3 Understanding How Knowledge Scripts Work

When a Knowledge Script is dropped on a target, one or more jobs may be created and sent to the target computers being managed. If the Knowledge Script is dropped on a single computer, one job is created and sent to that computer. If the Knowledge Script is dropped at a higher point in the hierarchy, there may be multiple managed client computers and thus multiple jobs may be created.

Each job represents the associated Knowledge Script running on the target managed client computer by the AppManager agent. Once started, the Knowledge Script job continues to run according to its schedule. If an event is detected or data is collected, the managed client sends the data or event information to the management server. The management server then transfers the data or event information to the central AppManager repository (QDB). The AppManager repository stores the information in its database.

Most Knowledge Scripts monitor the performance and availability of your servers or diagnose problems in your environment. In addition to these standard operations, there are four special types of Knowledge Scripts that perform specialized tasks and function a little differently:

- "Monitor-By-Proxy Knowledge Scripts" on page 2
- "Asynchronous Knowledge Scripts" on page 3
- "Local Configuration Knowledge Scripts" on page 3
- "Action Knowledge Scripts" on page 4

1.3.1 Monitor-By-Proxy Knowledge Scripts

Most Knowledge Scripts perform their tasks on the local computer on which you run them. However, some Knowledge Scripts run on one computer but allow you to specify one or more remote computers on which they are to perform their tasks.

Additionally, the tasks that are performed on the remote computer do **not** require the AppManager agent to present on the remote computer. For example, the NT_RemoteServiceDown Knowledge Script monitors services on other computers and General_MachineDown monitors whether a computer can communicate with remote computers.

AppManager provides the following proxy Knowledge Scripts:

- AnalyticsAlarm_ProcessClearEvents
- AnalyticsAlarm_ProcessTrustedAlarms
- General_MachineDown
- General_MachineDownLR
- General_PingMachine
- NT_RemoteServiceDown
- NT_RemoteServiceDownLR

Note that with the exception of General_MachineDown, which is configured to browse the repository for the list of remote computers you want, these Knowledge Scripts display event information in the Operator Console even if the remote computer is in maintenance mode.

When providing a list of Windows computers, you can specify computers that are not currently in the TreeView pane of the Operator Console. Note that if a remote computer is not in the TreeView pane of the Operator Console and this Knowledge Script raises an event on that computer, a server group named **AppManager Proxy Events** is automatically created in the **Master** view. From this group, you can view, acknowledge, close, and delete all events on the computer. To discover resources and run monitoring jobs on the computer, you must delete the computer from the **AppManager Proxy Events** server group, then manually add the computer to the TreeView. If necessary, stop any proxy jobs that are monitoring the remote computer so you can add it to the TreeView.

When configuring an action for monitoring-by-proxy Knowledge Scripts, you should configure the Location to initiate the action on the MS (to run on the management server) or on a Proxy (to run on a particular managed client computer).

If you instead configure an action to run on the managed client (MC), when a remotely monitored computer is placed into machine maintenance mode (from the Operator Console) or scheduled maintenance mode (using the AMAdmin_SchedMaint Knowledge Script), any event conditions detected on the remote computer are ignored but the action is not disabled; in this case, an action will be run but there will be no event information in the Events tab of the Operator Console.

1.3.2 Asynchronous Knowledge Scripts

Most Knowledge Scripts run once or on a schedule you specify. However, there are some Knowledge Scripts that run asynchronously whenever a certain event occurs. For example, Async_FilesChanged monitors one or more files for changes and raises an event when a change occurs. Instead of running a periodic check at a set interval, these Knowledge Scripts are always “active” and alert you whenever a new event occurs.

1.3.3 Local Configuration Knowledge Scripts

Most Knowledge Scripts run in accordance with parameters you set when you run the Knowledge Script. However, there are six Knowledge Scripts that get some parameter values from the local repository on the computer on which you run them. These parameter values are set by configuration Knowledge Scripts that you run in advance.

The combination of configuration Knowledge Scripts and local-repository Knowledge Scripts enables you to configure a group of computers differently as a one-time operation, then run the local-repository Knowledge Scripts as part of a monitoring policy on the whole group. The local-repository Knowledge Scripts behave differently on each computer in the group because they use the local parameter values instead of their own.

To understand how this works, consider the following configuration and local-repository Knowledge Script pairs:

NT_ConfigLogicalDisks
: Specifies the logical drives and thresholds to monitor. These parameters are then used locally by the **NT_LogicalDiskSpaceLR** and the **NT_LogicalDiskIOLR** local-repository Knowledge Scripts.

NT_ConfigServiceDown
: Specifies the services to monitor. This parameter is then used locally by the **NT_ServiceDown** local-repository Knowledge Script.

The other configuration Knowledge Scripts function in a similar way.

There are also AMAdmin Knowledge Scripts you can use to:

- View local repository (LR) configuration information: LRReadParameters
- Remove local repository (LR) configuration information: LRRemoveParameters
- Store local repository (LR) configuration information: LRWriteParameters

1.3.4 Action Knowledge Scripts

Most Knowledge Scripts run when you drag and drop them on a computer or a resource object in the TreeView. However, you never start Action Knowledge Scripts by dragging and dropping them onto an object. Instead, Action Knowledge Scripts are started indirectly by other types of Knowledge Scripts in response to events raised by those scripts.

To specify one or more Action Knowledge Scripts to run, use the Action tab of the script Properties dialog box when you set the properties for any other type of Knowledge Script.

1.4 Setting Knowledge Script Properties

Each Knowledge Script has properties you can modify. The Knowledge Script Properties dialog box is displayed when you:

- Double-click a Knowledge Script in the Knowledge Script pane of the Operator Console
- Select a Knowledge Script in the Control Center console
- Drag a Knowledge Script to the TreeView pane of the Operator Console
- Double-click a Knowledge Script job entry in the Jobs list

For most Knowledge Scripts, the Knowledge Script Properties dialog box lets you set the following:

Schedule
Every Knowledge Script has a default interval, for example, every five minutes, once a day, or only once. You can modify the schedule to use a different interval, to start and stop at specific times, or to run only once.

Values
Most Knowledge Scripts require some parameters to be set. The parameters vary depending on the purpose of each script, but the most common parameters allow you to raise events, set thresholds that will raise events, collect data for graphing and capacity planning, and set event severity levels. Default values are provided for most parameters, but you can easily modify them as needed.

Actions
These are the optional actions that a Knowledge Script can initiate if an event is detected. You can choose to raise one or more actions when an event is raised.

Objects
This tab lists the objects against which you have indicated you want the Knowledge Script to run. You can use this list to modify the objects to run against.

Advanced
This tab is used to set advanced job properties. It allows you to indicate whether you want duplicate events or the job collapsed into a single event, and the number of consecutive event occurrences to allow before raising an event in the Operator Console.

1.5 Viewing Job Results

Knowledge Scripts display the results of your jobs in several ways. What you see depends on whether your job is set for events, data collection, or both, or if the script runs into an error. For example, if a job is used to raise events, you see blinking icons in the Operator Console; if a job is used to collect data, you may view the results in a graph; if a job runs into an error, an Error status is displayed for the job under the Jobs tab.

1.6 Viewing Detailed Information

When events are generated as the result of a job, you can often get additional details about what happened by double-clicking the child event entry under the Events tab in the List pane. For example, the detail message for a TopCpuProcs Knowledge Script job includes a list of processes that consume the most CPU time. Depending on the Knowledge Script and the event, the detail message may include quite a lot of additional information about the problem found and how to correct it.

Similarly, when you run a Knowledge Script to collect data, the Knowledge Script creates one or more data streams that can be graphed. Once a data stream is graphed, double-clicking a data point on the graph displays a Graph Data Details dialog box that shows additional information about the data point selected.

1.7 Using Filters to Fine-Tune Searches

Some Knowledge Scripts search Windows event logs or other log files for specific types of information. In many cases, you can use a **filter** to fine-tune the types of information the Knowledge Script searches for. In the Values tab of the Knowledge Script Properties dialog box, a **Filter** parameter lets you specify a string of characters to look for.

1.7.1 How Filtering Works

Filtering is done through the combination of parameter values you set using partial string matching, without regard to case. For example, if you enter `Log` in the *Event Description* parameter, the filtering mechanism will include entries such as "The parameters specified for **log**ging are too long," and "The server failed to create a **log** context." For each filter you can specify the strings to include, exclude, or both.

1.7.2 Specifying Filters that Include Information

A filter searches for any entry that wholly or partially matches the search string that you specify. For example, for an **Event Description Filter** or **Filter the Event Description field** parameter (the wording may vary depending on the Knowledge Script), you might specify a search string of "MSExchange" or "Exchange" (the quotes aren't needed in the parameter field):

If this is the only filter you have specified, the Knowledge Script searches only the Description field in the log file and returns entries that include the string, such as MSExchangeAdmin, MSExchangeDSExp, MSExchangeDSImp, and MSExchangeSetup.

If you want the Knowledge Script to return all entries without filtering them, leave the filter parameter blank for text fields (such as a Computer Name), and specify 0 for fields containing numbers (for example, in the case of an Event ID).

1.7.3 General Rules for Matching Strings

For most filters, you can type any part of the text string you want to match and filtering is not case sensitive. If you specify a filter of "error" or "eRr", the Knowledge Script ignores capitalization and finds entries such as sys_err, error, Error, ERROR, and so on.

For example, you can filter the Source field in the Application event log for entries that have MSSQLServer as their source, by typing any part of that string for the Event Source filter (`ms`, `sql`, or `sqls` would all be valid search strings to find MSSQLServer):

NOTE: The exception to this rule is the Event ID filter, which requires a number. For the *Filter the Event ID field for* parameter, only exact matches are returned.

The filter string you specify can include spaces, underscores, and periods. For example, you can specify a very complete Event Description filter, such as "DHCP IP address lease 10.1.10.157".

Filters do not, however, recognize regular expressions or wild cards. If you specify a filter of "*32.dll" or "?32.dll" the Knowledge Script will search for entries that include the exact string you specified (`*32.dll` or `?32.dll`). Because file names cannot contain the * or ? characters, no entries will be returned.

1.7.4 Specifying Multiple Search Strings

You can specify multiple search strings for any filter by separating the strings with a comma and no extra spaces. For example to search the Event Description field for any of the following entries, enter:

```
DHCP IP address lease 10.1.10.157,20,error
```

In most cases, you can also combine filters to narrow matching entries further. For example, if you want to look for a specific event description occurring on any one of several specific computer names, you might set both the Event Description Filter and the Computer Filter:

If you specify multiple filters, the Knowledge Script searches only for entries that satisfy all of the search strings. For example, if you enter "1234" for the Event ID filter and "Fred" for the User field filter, the script only finds log entries that satisfy both filters.

1.7.5 Specifying Filters that Exclude Information

The information that you exclude from a search follows the same rules for including information: the Knowledge Script searches for partial matches and is not case-sensitive. The only difference is the format of the search string itself.

A single search string can specify information both to include and exclude. Separate the included and excluded strings with a colon (`included:excluded`). The string to the left of the colon is included in the search; the string to the right of the colon is excluded from the search. Separate multiple include or exclude entries with commas. For example, to search the Source field for entries that include the string "perf" and do not include the string "mon" or "lib", specify this filter parameter: `perf:mon,lib`.

Similarly, to search the **Computer** field for all Sales computers except those with Corp00 and HQ in their name, specify this filter parameter, `sales:corp00,HQ`.

The filter finds computer names such as NwSales, SalesEuro, and Corp02Sales but not NwSalesHQ or Corp00Sales.

To specify only the information to exclude, start the search string with a colon. For example, to search the Description field for all entries except those containing ODBC and RPC, specify this filter parameter: `:ODBC,RPC`.

If you are searching only for included strings, the colon is not necessary. For example, to search the Category field for entries with the string "SQL", specify this filter parameter: `SQL`.

1.7.5.1 Creating Filters with Regular Expressions

Some Knowledge Scripts enable you to use regular expressions to define include and exclude filters for pattern-matching against the text being evaluated. Depending on the Knowledge Script you are working with, you may be able to use regular expression include and exclude filters when you are setting job properties or you may be able to maintain your search criteria independent of the Knowledge Script parameters in a separate filter file. You may also be able to use regular expression modifiers to further refine your filtering.

For example, if your **include filter** looks like this `replic.*` and you specify the modifier `i` to make the search case-insensitive, the regular expression contains the wildcard (`.`) and repeat (`*`) special characters,

indicating you want to find strings that start with `replic` followed by any string of characters. Messages containing either `replication` or `replicated` are captured.

The format is the same for the exclude filter. For example, to find log entries that do not start with the string `success`, the exclude filter might look like this:

```
^success.*
```

If you are only searching for included strings, you can leave the exclude filter blank. If you want to retrieve all messages in the log in a given interval, you can specify `.*` for the include filter and leave the exclude filter blank.

1.7.5.2 Using Special Characters

The following special characters can be used in regular expressions:

Use This Character	For This Purpose
.	Wildcard for any one character
*	Repeat zero or more occurrences
^	Beginning of the line
\$	End of the line
\	Escape the next meta-character
|	Alternate matches
[ ]	Any character in the class set. You can specify individual characters or ranges.
( )	Grouping characters. For example, you can specify (a|b|c) to indicate a match with a, or b, or c.
+	Quantifier indicating one or more occurrences
?	Quantifier indicating zero or one occurrence
{*n*}	Quantifier indicating exactly *n* occurrence
\w	A word character (alphanumeric plus _)
\s	A white-space character
\d	A digit character

1.7.5.3 Using Regular Expression Modifiers

In addition to the special characters you can use in creating the regular expression, there are a number of modifiers that can be used to modify how pattern-matching is handled. For additional information about writing regular expressions, see your Perl documentation or other regular expression resources. Valid modifiers include:

Modifier	Description
c	Complements the search list
g	Matches globally as many times as possible
i	Makes the search case-insensitive

Modifier	Description
m	Treats the string as multiple lines
o	Interpolates variables only once
s	Treats the regular expression string as a single long line
x	Allows for regular expression extensions

1.8 Running Knowledge Scripts that Require Special Privileges

AppManager agent services can run either as the `LocalSystem` account or as a valid user account that you designate. By default, the two agent services are installed to run using the Windows `Local System` account, and in most cases, this account is sufficient for running a wide range of Knowledge Script jobs.

Some Knowledge Scripts, however, require the AppManager agent services to run using special account permissions or privileges to get information from a managed client or perform certain tasks. When the Reference Guide agent runs under a user account, that account is typically called the **service account**.

A few Knowledge Scripts and managed objects require the AppManager agent services to run using a Windows login account that has Administrator privileges for the domain, that is, the account must be a member of **Domain Admins** and not just an Administrator for the local computer. It is the Domain Admins privilege that enables the Knowledge Scripts to read certain Performance Monitor counters, access protected files, or perform restricted actions such as creating directories and copying files on remote computers.

Other Knowledge Scripts have other account requirements. For example, some Exchange Knowledge Scripts require Exchange Admin permissions.

Review the *Management Guide* for each application you plan to monitor before you install agents on those servers. The management guides, which are included in application-specific folders under the `\Documentation\Management Guides` folder of the AppManager installation kit, provide lists of Knowledge Scripts that require special privileges and also contain instructions for changing the account under which the agent services are running.

1.8.1 Setting Up a Service Account

You can use an existing account or create a new account specifically for the agent services to use. To set the service account:

1. Use the Windows **Computer Management** tool or Windows 2000 **Active Directory** to set up or find an account with the appropriate privileges. For example, check that the user account is a member of the Domain Admins group.
2. Open the **Services** Control Panel and select the NetIQ AppManager Client Resource Monitor service.
3. Click **Stop** and wait for the service to stop.
4. On the Log On tab, click **This account**, then provide the user account and password you identified in Step 1.
5. On the General tab, click **Start** to restart the service.
6. Repeat Step 2 through Step 6 for the NetIQ AppManager Client Communication Manager service.

1.8.2 Running Administrator-Only Knowledge Scripts

Some Knowledge Scripts perform AppManager administrative tasks or operations that should be restricted to a limited number of users. To control access to these Knowledge Scripts, the scripts are only made available to users who are assigned to the Administrator role through Security Manager.

Most of the administrative Knowledge Scripts are in the Action, AMAdmin, and NTAdmin categories, and by default these Knowledge Scripts are designated as being for administrators only. You can, however, modify the administrator-only setting for any Knowledge Script through an option in the Developer's Console.

For more information about modifying Knowledge Scripts, see *Developing Custom Knowledge Scripts* for AppManager. For information about assigning users to security roles, see the Security Manager Help or the *Administrator Guide*.

1.9 Getting Online Help for Knowledge Scripts

To get Help for any Knowledge Script:

- Highlight the Knowledge Script in the Knowledge Script pane in the Operator Console and press **F1**.
- Select **Help Topics** from the Help menu and use Index or Find to look for the Knowledge Script you are interested in.
- Click the **Help** button while viewing the Values tab in the Knowledge Script Properties dialog box.

Online help is not provided for contributed, unsupported, or custom Knowledge Scripts.

2 Action Knowledge Scripts

The AppManager Action Knowledge Scripts perform corrective or responsive actions when events are raised. From the Knowledge Script view of Control Center, you can access more information about any NetIQ-supported Knowledge Script by selecting it and clicking **Help**. In the Operator Console, click any Knowledge Script in the Knowledge Script pane and press **F1**.

Knowledge Script	What It Does
AddComputerToServerGroup	Adds a CallManager to a CallManager cluster based on its Publisher.
Diagnose	Triggers AppManager Diagnostic Console to run a diagnosis of the target computer.
DiagnoseNortelIPT	Triggers NetIQ Vivinet Diagnostics to run a diagnosis of VoIP quality in a Nortel CS1000 IP Telephony environment.
DiagnoseVoIPQuality	Triggers NetIQ Vivinet Diagnostics to run a diagnosis of voice quality between two phones or two endpoints.
DominoCommand	Issues a Domino command to a Domino server.
DosCommand	Runs a non-interactive DOS command.
DumpTran	Dumps or truncates the SQL Server transaction log.
ExtendedSNMPTrap	Sends an extended SNMP trap message to a specified list of computers.
IISContinueSite	Continues a paused Internet Information Services (IIS) site.
IISPauseSite	Pauses an IIS site.
IISRestartServer	Restarts an IIS server.
IISRestartSite	Restarts an IIS site.
MapiMail	Sends mail to one or more email users.
Messenger	Sends a Messenger service message that contains AppManager event information to a specified computer.
NetAppFilerDoSnapMirror	Opens a Telnet session on the specified Network Appliance filer and issues a snapmirror command.
NetAppFilerIssueCommand	Opens a Telnet session on the specified Network Appliance filer and issues a non-interactive maintenance command.
NetAppFilerReboot	Opens a Telnet session into a specified Network Appliance filer and issues a reboot command.
NotesMail	Sends mail to one or more Lotus Domino/Notes email users.
NTEventLog	Writes an event to the Windows Event Log.
Page	Sends a paging call to one or more recipients in response to an event.

Knowledge Script	What It Does
RebootSystem	Shuts down and restarts a computer when an event is raised.
RestartServices	Stops and restarts Windows services.
RunDiscoveryCiscoCallMgr	Used with CiscoCallMgr_CCM_RoleStatus to rediscover resources that move when a CallManager role changes.
RunDiscoveryNetworkDevice	Used with NetworkDevice_Device_Uptime to rediscover devices that reboot during monitoring.
RunKS	Runs up to three other Knowledge Scripts.
RunPhoneInventory	Used with CiscoCallMgr_LossOfHardwarePhones to produce a phone inventory on the associated Publisher.
RunPowerShell	Runs a non-interactive Windows PowerShell command.
RunSql	Runs SQL statements or stored procedures.
SendReportToPrinter	Sends a report to the printer that is the default for the managed client on which the Report agent is running.
SMTPMail	Sends mail using SMTP to one or more users.
SMTPMailRpt	Sends the first page of a report to a list of recipients.
SNMPTrap	Sends an extended SNMP trap to one or more computers.
StartServices	Starts specified Windows services.
StopServices	Stops specified Windows services.
Traceroute	Collects exception traceroute data between a specified source and target location in response to an event in a separate Knowledge Script.
TracerouteNetworks-RT	Collects exception traceroute data between a specified source and target location in response to an event in a separate Networks-RT Knowledge Script.
UpdateEventStatus	Provides AppManager event status details from one or more specified computers.
UXCommand	Runs a non-interactive UNIX command in response to an event.
WriteMsgToFile	Writes AppManager event information to a specified file.

2.1 AddComputerToServerGroup

Use this Knowledge Script to add a Cisco CallManager server to a CallManager cluster based on its Publisher. This script raises an event if the job is successful.

2.1.1 Prerequisite

NetIQ Object Linking and Embedding (`NetIQOLE`) must be registered on the computer on which this script runs. `NetIQOLE` is an automation object that allows AppManager to be run from a command-line. For more information, see the *Administrator Guide for AppManager* at the NetIQ AppManager Documentation Web site.

2.1.2 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Event for success?	Set to y to raise an event when the process is successful.
Event level for success	Set the severity level, from 1 to 40, to indicate the importance of an event in which a CallManager servers is successfully added to a cluster.

2.2 Diagnose

Run this Knowledge Script to trigger AppManager Diagnostic Console to diagnose a problem on a *target* computer that has raised an event. The diagnosis is driven from the *console* computer specified in the **Location** field on the **Action** tab.

When launched, Action_Diagnose performs the following steps:

- Verifies that Diagnostic Console 2.1 or later is installed. If Diagnostic Console 2.1 or later is not installed, this script raises an event indicating that the diagnosis cannot be performed.
- Determines whether Action_Diagnose is already running on the console computer. If a diagnosis is already running, Action_Diagnosis raises an event indicating that a diagnosis is in progress. Only one instance of Action_Diagnose can be running at any given time.
- Invokes Diagnostic Console to perform the diagnosis and generate an `.html` diagnostic report. Diagnostic Console collects Windows, Exchange, or Active Directory data based on the configuration of the target computer.

  NOTE: The target computer must have Diagnostic Console version 2.1 or later installed in order for Active Directory data to be collected. Windows and Exchange data can be collected with Diagnostic Console version 2.0 or later.

- Generates a report using the *Output folder prefix* and *Use Report Agent settings* parameters, or the *Full path to root of output folders* parameter if you are not using the Report agent.
- Upon completion of the diagnosis, raises an event that contains the results of the diagnosis. An event for a successful diagnosis will contain either a URL to the `default.htm` file (if *Use Report Agent settings* is set to y) or the computer name and full path of the location of the output files. An event for an unsuccessful diagnosis contains an error message explaining why the diagnosis was unsuccessful.

2.2.1 Prerequisite

NetIQ Object Linking and Embedding (`NetIQOLE`) must be registered on the computer on which this script runs. `NetIQOLE` is an automation object that allows AppManager to be run from a command-line. For more information, see the *Administrator Guide for AppManager* at the NetIQ AppManager Documentation Web site.

2.2.2 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Length of time to run diagnosis	Enter the amount of time that you want a Diagnosis to run. The default is 300 seconds. The maximum allowable run time is 900 seconds. A longer run time will produce more data than reports can generate in a timely fashion. The minimum allowable run time is 60 seconds. A shorter run time is not enough for the agent to collect data and send it to the repository.

Parameter	How to Set It
SQL Login Name	Enter the SQL user name required for access to the Appmanager repository when collecting Exchange and Active Directory data. Leave this parameter blank to use NT Authentication for accessing the repository.
SQL password	Enter the SQL password required for access to the AppManager repository when collecting Exchange and Active Directory data.
Output folder prefix	Enter a prefix for the output folder that is generated by the diagnosis. The output folder then uses this prefix in the following naming convention: *Prefix_ComputerName_DateTime*. The default prefix is `Diag`. **NOTE:** The `ComputerName` is the name of the computer being diagnosed.
Use Report Agent settings?	Set to y to specify that the Diagnostic results should be integrated into the AppManager Web management server (the Report Binder). The default is y.
Full path to root of output folders	Enter the full path to the root of where the output folders will be created. **NOTE:** This parameter is ignored if **Use Report Agent settings** is enabled.
Event severity when · · ·	Enter a severity level, between 1 and 40, to indicate the importance of the following events: • error. Raises an event when the diagnosis does not complete successfully. The default is 15. • successful. Raises an event when the diagnosis completes successfully. The default is 35.

2.3 DiagnoseNortelIPT

Run this Knowledge Script in your Nortel Communication Server 1000 IP Telephony environment to trigger NetIQ Vivinet Diagnostics to diagnose a call quality problem between two Nortel IP phones.

Configure this Action on the NortelCS_Alarms Knowledge Script. A Diagnosis is triggered when the Alarms script raises events for the following QoS alarms (SNMP traps): QOS0022, QOS0024, QOS0026, QOS0028, QOS0030, QOS0032, and QOS0034. The Diagnosis makes use of the RTCP-XT statistics included in the SNMP trap.

You must run this Action on a computer where Vivinet Diagnostics 2.0 (or later) is installed. In addition, you must have already configured Vivinet Diagnostics with the security information for accessing the Call and Signaling Servers. For more information, see the *User Guide for Vivinet Diagnostics*.

Only one Diagnosis can run at any time. If a second Action is triggered while a Diagnosis is already in progress, the second Action will complete, but indicate that it could not run the Diagnosis because another was already in progress. To see the status of the Action for any event, click the **Action** tab of the event.

When the Diagnosis has completed, the Action Knowledge Script raises an event that identifies the location of the Vivinet Diagnostics `.dgv` file, which contains the results of the Diagnosis. In addition, if the Web management server and Report agent are installed on the computer that is running the Action, you can enable the **Use Report Agent settings** parameter, which integrates the Diagnosis results with other reports generated by the Report agent. The results are then easily accessible from the Web management server Report Binder and from the Operator Console's **Extensions > Report Viewer** function.

TIP: To allow this script to trigger a Diagnosis with Vivinet Diagnostics whenever a problem occurs, you need to disable or modify the "event collapsing" feature on the NortelCS_Alarms script. Event collapsing allows AppManager to suppress, or collapse, what it considers to be duplicate events. However, you will probably want Vivinet Diagnostics to diagnose a problem each time one occurs, even if it occurs between the same two targets. And you cannot do that if AppManager has collapsed all call quality events between the same targets into one event. Use the Advanced tab of the NortelCS_Alarms script to disable event collapsing, or at least to modify the 20-minute collapsing interval.

2.3.1 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Output folder prefix	Enter a prefix for the output folder that is generated by the Diagnosis. The output folder then uses this prefix in the following naming convention: *Prefix_JobID_Phone1_Phone2_DateTime*. The default prefix is `Diag`. `Phone1` and `Phone2` are the IP addresses of the two Nortel phones being diagnosed. The `ComputerName` is the name of the computer being diagnosed.
Use Report Agent settings?	If enabled, the diagnostic results are integrated into the AppManager Web management server (the Report Binder). The default is y.

Parameter	How to Set It
Full path to root of output folders	Enter the full local or UNC path to the root of the directory in which you want to create the output folders. Make sure that the `NetIQmc` service (NetIQ AppManager Client Resource Monitor) is configured to run as a user that has access to the UNC path. The default setting of “local system” does not have access to the UNC path. Without access to the path, Vivinet Diagnostics will not be able to save a Diagnosis to the output folder. **NOTE:** This parameter is ignored if **Use Report Agent settings** is set to y.
Event Notification	
Severity when diagnosis successful	Enter a severity level, between 1 and 40, to indicate the importance of an event that is raised when the Diagnosis completes successfully. The default is 35.
Severity when error encountered	Enter a severity level, between 1 and 40, to indicate the importance of an event that is raised when an error prevents the Diagnosis from completing successfully. The default is 15.

2.4 DiagnoseVoIPQuality

Use this Action Knowledge Script to trigger NetIQ Vivinet Diagnostics to run a Diagnosis of voice quality between two phones or two endpoints. A Diagnosis is performed when a threshold is exceeded when you run any of the following Knowledge Scripts:

- **AvayaCM_CallQuality**. Vivinet Diagnostics can diagnose the problem when average MOS, average R-Value, average jitter, average latency, and average packet loss fall below or exceed their thresholds.
- **AvayaCM_PhoneQuality**. Vivinet Diagnostics can diagnose the problem when MOS, R-Value, jitter, latency, and packet loss fall below or exceed their thresholds during the data collection interval.
- CiscoCallMgr_CallQuality. Vivinet Diagnostics can diagnose the problem when jitter, latency, and percentage of lost data exceed their thresholds.
- CiscoCallMgr_CallFailures. Vivinet Diagnostics can diagnose the problem when the number of failed calls exceeds its threshold.
- **NortelCS2x_CallQuality**. Vivinet Diagnostics can diagnose the problem when end-of-call values for MOS and R-value fall below their thresholds, and when end-of-call values for jitter, latency, and packet loss exceed their thresholds.
- **NortelCS2x_PhoneQuality**. Vivinet Diagnostics can diagnose the problem when mid-call values for MOS and R-value fall below their thresholds, and when mid-call values for jitter, latency, and packet loss exceed their thresholds.
- **PhoneQuality_CiscoPhoneQuality**. Vivinet Diagnostics can diagnose the problem when the values for listening MOS and listening R-value fall below their thresholds, and when the values for average jitter, maximum jitter, and packet loss exceed their thresholds.
- VoIPQuality_CallPerf_<name of script>. Vivinet Diagnostics can diagnose the problem when MOS, R-factor, delay, jitter buffer loss, and percentage of lost data exceed their thresholds.

NOTE: This script is supported only when Vivinet Diagnostics 1.1 or later is installed. In addition, this script does not work when triggered by Knowledge Scripts other than those listed above.

When launched, Action_DiagnoseVoIPQuality performs the following steps:

- Verifies that Vivinet Diagnostics 1.1 or later is installed. If Vivinet Diagnostics 1.1 or later is not installed, this script raises an event indicating that Vivinet Diagnostics 1.1 is required.
- Verifies that you have elected to run this Action Knowledge Script based on an event raised by the running of an applicable script. If you choose to initiate this script based on some other Knowledge Script, this Action script raises an event indicating that the Action script cannot invoke Vivinet Diagnostics from the <*script name*> Knowledge Script.
- Determines the number of Diagnoses that need to be performed based on the parameters that you set in the above-mentioned scripts, as well as the thresholds that were reached or exceeded.
- Invokes Vivinet Diagnostics to perform the Diagnosis and generate an `.html` diagnostic report.
- If *Use Report Agent settings?* is disabled, generates a `default.rptIndex.xml` file and a small `default.htm` file that contains hyperlinks to the `.dgv` file and the Vivinet Diagnostic report.
- Upon completion of the Diagnosis, raises an event that contains the results of the Diagnosis. An event for a successful Diagnosis contains either a URL to the `default.htm` file (if *Use Report Agent settings?* is enabled) or the name of the computer and full directory path to the output files. An event for an unsuccessful Diagnosis contains an error message explaining why the Diagnosis was unsuccessful.

For a more in-depth discussion of the integration of Vivinet Diagnostics and AppManager, see the *User Guide for Vivinet Diagnostics*.

NOTE: Before running this script, you must first configure Vivinet Diagnostic with information about your VoIP setup. AppManager passes phone data, such as the calling party or the called party, to Vivinet Diagnostics, and then Vivinet Diagnostics starts the diagnosis using the phone data from AppManager and the VoIP setup information you configured in Vivinet Diagnostics. Be aware that AppManager will not raise an alert if the information about your VoIP setup is missing from Vivinet Diagnostics.

The following list covers what you must configure for Vivinet Diagnostics, based on your VoIP setup:

- Nortel Call Server Signaling Server (for Nortel phones)
- Cisco Call Manager (for Cisco phones)
- SNMP information (for all VoIP phones)

For more information, see the *User Guide for Vivinet Diagnostics*.

2.4.1 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Event severity when error	Set the severity level, between 1 and 40, to indicate the importance of an event in which a diagnosis does not complete successfully. The default is 15.
Event severity when successful	Set the severity level, between 1 and 40, to indicate the importance of an event in which a diagnosis completes successfully. The default is 35.
Output folder prefix	Enter a prefix for the output folder that is created by the Diagnosis. The output folder then uses this prefix in its naming convention as follows: *Prefix_JobID_ComputerName_DateTime*. **NOTE:** The *ComputerName* is the name of the CallManager computer or talker/listener computer. If a single event triggers multiple Diagnoses, a sequence number (0, 1, 2, 3, 4) is appended to the output folder name. The output folder contains the `.dgv` file, the diagnostic `.html` report file, and, if integrated with the report-enabled agent, a `default.rptIndex.xml` file, and a `default.htm` file that contains hyperlinks to both the `.dgv` file and the diagnostic `.html` report.
Use Report Agent settings?	Select **Yes** to integrate the Diagnostics results into the AppManager Web management server (the Report Binder). The default is Yes.
Full path to root of output folders	Provide the full path to the root of where the output folders will be created. **NOTE:** Ignore this parameter if *Use Report Agent settings?* is set to **Yes**.
Maximum diagnoses	Specify a number between 1 and 5 to indicate the maximum number of Diagnoses that can be triggered by a single event. **NOTE:** This parameter is applicable only for events generated by the CiscoCallMgr_CallQuality and CiscoCallMgr_CallFailures scripts, where one event may identify multiple pairs of phones that indicate a problem.

2.5 DominoCommand

Use this Knowledge Script to issue a Domino command to a Domino Server. This script can enable you to run a Domino command as a corrective action in response to an event. For example, the Knowledge Script Domino_LogSniff monitors the Notes log database for specific messages or search strings. If you locate corruption in a database by running Domino_LogSniff, you can set that Knowledge Script to run the Action_DominoCommand Knowledge Script with the corrective Domino command or Domino agent you specify. The Domino command `Fixup`, for example, locates and repairs corrupted databases.

DominoCommand raises an event when the command is completed. The event message indicates whether or not the command was successful, and provides an explanation if the command fails.

NOTE: This Action can run only on the managed computer as a Managed Client Action. Select **MC** (Managed Client) on the Action tab of the Properties dialog box when enabling this Action.

2.5.1 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Command	Specify the Domino command to be executed, using Domino command delimiters. For example, the default command, 0|#show task, includes the following elements: • the partition number of the Domino server to which the command is being sent. If the computer contains only one instance of a Domino server, enter 0 • the vertical bar, | • the pound sign, # • the command, show task Domino commands must follow this format.

2.6 DosCommand

Use this Knowledge Script to run a non-interactive DOS command when an event is raised. For example, use this script to run a batch command for virus scanning, disk backup, or logging an entry in a trouble-ticket system.

You can include arguments in the command string. This script can also test your command-line syntax.

Use this Knowledge Script to create a script file that contains a series of commands to diagnose or correct problems on a server you are monitoring. You can then have this Action launch your script file when an event is detected. For example, enter: `cmd /c \fixitscript.bat`.

To ensure the command runs successfully:

- Include the full path to the executable you want to run. For example, to issue a `Ping` command, you may need to enter a command similar to the following:

  ```
  cmd /c \ping.exe 164.210.210.1.
  ```

- Be sure that the command you want to run does not require any user input.
- To run this Action on the managed computer, select **MC (Managed Client)** as the Location on the Action tab of the Properties dialog box.
- Check whether the computer where you want to run a command or script file accepts commands from the management server you are using. This access is controlled through the `AllowDosCmd` registry key setting. By default, the `AllowDosCmd` key is set to `*` to allow all management servers to initiate DOS commands. To restrict the management servers that are allowed to run DOS commands, you can set this key to a comma-separated list of computer names. For example, `AllowDosCmd:REG_SZ:shasta,dynamo`.
- Verify that the AppManager Client Resource Monitor (`NetIQmc`) service account, whether it be the `LocalSystem` account or a user account, has permission to execute the command you want to run on the computer where you want the Action executed.

2.6.1 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Event Notification	
Event severity – Action failure	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the DosCommand job fails. The default is 5 (red event indicator).
Severity Configuration	
Minimum event severity for Action	Set the minimum severity level, from 1 to 40, for an event that triggers this Action. The default is 1.
Maximum event severity for Action	Set the maximum severity level, from 1 to 40, for an event that triggers this Action. The default is 40.
Action	

Parameter	How to Set It
Non-interactive DOS command	Specify the command to run. Do not enter a command that requires user input. The command you enter should take care of any input and output redirection or handling required. The default is `del\temp\yunk.txt`. **NOTE:** If the command you are entering includes quotation marks ("), enclose the quoted string in a second set of quotation marks. For example, if the DOS command is `net send "message"`, enter the following: `cmd /c net send ""message""`. You can use the following keywords in the command: • `$ShortMsg$` (short event message) • `$DetailMsg$` (detailed event message) • `$Time$` (date and time of the event) • `$JobID$` (ID of the job that raised the event) • `$MachineName$` (name of the computer where the event was raised) • `$Severity$` (severity of the event) • `$KSName$` (name of the Knowledge Script that raised the event) • `$ObjectName$` (name of the AppManager resource object where the event was raised) • `$EventID$` (event ID) For `$ShortMsg$` and `$DetailMsg$`, you can use number and wildcard options to indicate specific portions of the text string to include. For example: • `$DetailMsg$[5]` includes the fifth word of the detailed event message • `$ShortMsg$[1-5]` includes the first through fifth words of the short message event • `$DetailMsg$[*5]` includes the first through fifth words of the detailed event message • `$ShortMsg$[5*]` includes the fifth through last words of the short event message If you do not enter a word specifier, AppManager returns the entire string. **Example** To print a detail message starting from the eighth word into `c:\temp\log.txt`, type the following command: `echo $DetailMsg$[8*] > c:\temp.log.txt`
Normal/Expected exit code	Set the normal/expected exit code for the DOS command you enter. The default is 0.
Test command-line syntax?	Select **Yes** if you want to test the command-line syntax you specified for the *Non-interactive DOS command* parameter. The default is unselected.
Event severity – Test command	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the test command runs successfully. The default is 35 (magenta event indicator).

2.7 DumpTran

Use this Action Knowledge Script with selected SQL Knowledge Scripts (such as DataSpace, DBSpace, and LogSpace) to dump the transaction log of a database when an event is raised. For example, if the DBSpace Knowledge Script detects that the database space available has fallen below the threshold, you can use this Action to automatically dump the transaction log to free up space. Syntax and permission checking is handled by SQL Server.

When configuring this action, keep in mind:

- The Action can run only on the managed computer as a Managed Client Action. Be sure to select **MC** (Managed Client) as the Location on the Action tab of the Properties dialog box.
- This script requires an account with System Administrator privileges or dbo privileges to run. If you run this Action on SQL Server 7, the Dump Transaction can be done by a dbo or db_backup operator account. For more information about the permissions required for a Dump Transaction command, see your SQL Server documentation.
- This script requires a database name supplied by the SQL Knowledge Script to perform the dump. If the Knowledge Script that raises the event is running with the *Dynamically observe databases at each interval?* parameter enabled (so that it dynamically discovers database names at run time), the Action will fail. To use this Action, disable the *Dynamically observe databases at each interval?* parameter in the DataSpace, DBSpace, or LogSpace Knowledge Script.

This Action can only operate on a database whose recovery model is either Full or Bulk-Logged.

2.7.1 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
SQL login	Specify the database user account used to run this Knowledge Script, for example, `sa`. You can run this Knowledge Script using other user accounts that have been set up in the SQL Server of the managed client and have been given permission to run SQL Knowledge Scripts through the AppManager Security Manager.
Truncate only?	Set to y to truncate the transaction log, without saving the truncated information to any location. If set to n, you must specify where the transaction log should be sent in the TO statement parameter. The default is n.
TO statement	If *Truncate only?* is disabled, enter a TO statement to specify where the truncated transaction log should be sent. The default is `to diskdump`.

2.8 ExtendedSNMPTrap

Use this Knowledge Script to send an extended SNMP trap message with AppManager event information to a specified list of computers. The event information includes the event severity level.

Each computer you specify must be able to receive SNMP trap messages on UDP port 162.

If you do not specify a value for any of the parameters, this Knowledge Script uses the corresponding value found in the registry under `HKEY_LOCAL_MACHINE\Software\NetIQ\AppManager\4.0\NetIQmc\SNMPTRAP\Config`.

For example, if you do not specify an object identifier in the OID field, the Knowledge Script checks the registry for the OID key entry: `OID: REG_SZ: 1.3.6.1.4.1.1691.1`.

When associating the ExtendedSNMPTrap Knowledge Script with a monitoring job, carefully choose the location of the action. Location options are available on the Action tab of the Properties dialog box

- When Location = `MC`, the trap will not include fields for Event Identifier, Repository Name, and Repository Server, because this information is not available on the AppManager agent.
- When Location = `MS` or Location = `proxy`, the trap will include fields for Event Identifier, Repository Name, and Repository Server. However, if many jobs are configured to send traps with the management server, performance on the management server computer may be adversely affected.

2.8.1 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
List of computers to receive SNMP message	Provide the name of the computer to receive the SNMP trap message. The receiving port is port 162. To specify multiple recipients, separate computer names with commas and no spaces. For example, `Nancy01,Finance03` If this field is left blank, the local host is the recipient by default.
Community string	Provide a valid SNMP community string. Leave this parameter blank to use the SNMP community string entered in AppManager Security Manager. If no SNMP community string is entered in Security Manager, the “public” SNMP community string is used by default.
Object identifier	Enter an object identifier in OID notation (for example, 1.2.3.456.78). If no value is entered, this script uses the OID notation entered in the following registry key: `SOFTWARE\NetIQ\AppManager\4.0\NetIQmc\SNMPTRAP\Config`
Specific trap number	Enter a trap number. The trap number can be specific to your application. If no value is entered, this script uses the trap number entered in the following registry key: `SOFTWARE\NetIQ\AppManager\4.0\NetIQmc\SNMPTRAP\Config`

2.9 IISContinueSite

Use this Knowledge Script to continue a paused IIS site. This script raises an event if the script is unable to continue a paused IIS site.

This Action can run only on the managed computer as a managed client Action. Be sure to select **MC** (managed client) as the Location on the Action tab of the Properties dialog box. This Action cannot run as a management server (MS) Action.

When you use this Action with a Knowledge Script that supports dynamic observation and you enable the *Dynamic observation* parameter, you can only run the Knowledge Script on one Web site at a time. If you disable dynamic observation, you can run the Knowledge Script on all Web sites.

2.9.1 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if attempt to continue fails?	Set to y to raise an event if the attempt to continue a paused IIS site fails. The default is y.
Event severity when site cannot be continued	Set the event severity level, from 1 to 40, to indicate the importance of an event in which a paused IIS site cannot be continued. The default severity level is 7 (red event indicator).

2.10 IISPauseSite

Use this Knowledge Script to temporarily pause an IIS site. This script raises an event if the IIS site cannot be paused.

This Action can only run on the managed computer as a managed client Action. Be sure to select **MC** (managed client) as the Location on the Action tab of the Properties dialog box. This Action cannot run as a management server (MS) Action.

When you use this Action with a Knowledge Script that supports dynamic observation and you enable the *Dynamically observe Web servers at each interval* parameter, you can only run this Knowledge Script on one Web site at a time. If you disable dynamic observation, you can drop the Knowledge Script on all Web sites.

2.10.1 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if attempt to pause fails?	Set to y to raise an event if the attempt to pause an IIS site fails. The default is y.
Event severity when site cannot be paused	Set the event severity level, from 1 to 40, to indicate the importance of an event in which an IIS site cannot be paused. The default severity level is 7 (red event indicator).

2.11 IISRestartServer

Use this Knowledge Script to stop and then restart an IIS server. This script raises an event if the attempt to stop or restart a service fails or succeeds. Any services that are stopped when the job runs can also be detected and started.

When you use this Action with a Knowledge Script that supports dynamic observation and you enable the *Dynamically observe Web servers at each interval* parameter, you can only run this Knowledge Script on one Web site at a time. If you disable dynamic observation, you can run the Knowledge Script on all Web sites.

2.11.1 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if attempt to restart fails or succeeds?	Set to y to raise an event if the IIS server cannot be restarted, or if the server is successfully restarted. The default is y.
Restart server?	Set to y to restart an IIS server. The default is y.
Start all stopped services?	Set to y to start all stopped services. The default is n.
Severity when restart...	Set the event severity level, from 1 to 40, to indicate the importance when the attempt to restart stopped services: **... fails**. Type a value that indicates the service is down and AppManager cannot restart it. The default is 10 (red event indicator). **... succeeds**. Type a value that indicates the service was down and AppManager successfully restarted it. The default is 20 (blue event indicator).

2.12 IISRestartSite

Use this Action Knowledge Script to shut down and restart an IIS site instance. This script raises an event if the IIS site cannot be shut down or restarted.

This Action can only run on the managed computer as a managed client action. Be sure to select **MC** (managed client) as the Location on the Action tab of the Properties dialog box. This Action cannot run as a management server (MS) Action.

When you use this Action with a Knowledge Script that supports dynamic observation and you enable the *Dynamically observe Web servers at each interval* parameter, you can only run this Knowledge Script on one Web site at a time. If you disable dynamic observation, you can run the Knowledge Script on all Web sites.

2.12.1 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if attempt to shut down or restart fails?	Set to y to raise an event if the attempt to shut down or restart an IIS site instance fails. The default is y.
Restart site after shutdown?	Set to y to restart an IIS site after it is shut down. The default is y.
Event severity when attempt to shut down or restart IIS site fails	Set the event severity level, from 1 to 40, to indicate the importance of an event in which an IIS site cannot be shut down or restarted. The default severity level is 7 (red event indicator).

2.13 MapiMail

Use this Knowledge Script to send a MAPI email message with AppManager event information to a specified list of recipients.

By default, the event information includes the computer name of the managed client and the event severity. You can select additional information to include. You can also construct a custom message to send to recipients.

This script raises an event if you select the custom message format but neglect to enter any text for the custom message body. Under these circumstances, the script continues to execute and uses the standard message format.

You can attach a file to the email message by entering the path to the file.

The email message is sent using the Microsoft MAPI mechanism. The recipients can be one or many MAPI clients.

NOTE: Because Microsoft tightened security in recent versions of Microsoft Outlook, the MapiMail script works only with Outlook 2000 and Outlook 2003 SP1. This script is not supported on the following versions of Outlook:

- Outlook 2003 without service packs
- Outlook 2003 SP2
- Outlook 2007
- Outlook 2010

As an alternative, consider using the SMTPMail Knowledge Script.

2.13.1 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Event Notification	
Event severity – Action warning	Set the severity level, from 1 to 40, to indicate the importance of an event in which the MapiMail job returns a warning. The default is 35 (magenta event indicator).
Event severity – Action failure	Set the severity level, from 1 to 40, to indicate the importance of an event in which the MapiMail job fails. The default is 5 (red event indicator).
Severity Configuration	
Minimum event severity for Action	Set the minimum severity level, from 1 to 40, for an event that triggers this Action. The default is 1.
Maximum event severity for Action	Set the maximum severity level, from 1 to 40, for an event that triggers this Action. The default is 40.
Action	
Profile name	Provide the profile name of the managed client, such as the default netiq account or an account set up specifically for the client. The profile must be an account with Mail capability.

Parameter	How to Set It
List of recipients	Provide the email address for the recipient of the message, using names in the address book. Separate multiple names with semicolons (;). For example: `Chris Lin;pat@bigcorp.com;gwest`. **NOTE:** Be sure the names you enter are not ambiguous. If the script cannot definitively identify the recipient, mail is not sent.
Full path to mail attachment	Provide the full path to the attachment you want to send. If you are not attaching a file, leave this field blank.
Message format	Select the format you want to use for the message sent by this script: • **Standard** format generates a message based upon the selections you make from the *Standard Message Options* parameters. • **Custom** format generates a message based upon the subject and message body you supply in the *Custom Message Options* parameters. The default is Standard.
Standard Message Options	
Include date/timestamp?	Select **Yes** to include the date/timestamp in the standard message. The default is unselected.
Include JobID?	Select **Yes** to include the job ID in the standard message. The default is unselected.
Include agent computer name?	Select **Yes** to include the name of the agent computer in the standard message (the computer hosting the agent that initiated the action). The default is Yes.
Include event severity?	Select **Yes** to include the severity of the event in the standard message. The default is Yes.
Include Knowledge Script name?	Select **Yes** to include the Knowledge Script name in the standard message (the Knowledge Script that initiated the Action). The default is unselected.
Include AppManager object name?	Select **Yes** to include the AppManager resource object name in the standard message (the AppManager resource object where the event was raised). The default is unselected.
Include AppManager event ID (only on MS Action)?	Select **Yes** to include the AppManager event ID in the standard message (possible only in cases when the Action is carried out by the management server). The default is unselected.
Include event detail message?	Select **Yes** to include the event detail message. The default is unselected.
Custom Message Options	
Custom message subject	Provide the text you want to use for the custom message subject line.

Parameter	How to Set It
Custom message body	Provide the text you want to include in your custom message. You can use the keywords listed below to indicate the information you want to include in the body of your custom message. Add a space before and after keywords to ensure that the keywords display properly. • `$ShortMsg$` (short event message) • `$DetailMsg$` (detailed event message) • `$Time$` (date and time of the event) • `$JobID$` (ID of the job that raised the event) • `$MachineName$` (name of the computer where the event was raised) • `$Severity$` (severity of the event) • `$KSName$` (name of the Knowledge Script that raised the event) • `$ObjectName$` (name of the AppManager resource object where the event was raised) • `$EventID$` (event ID) For `$ShortMsg$` and `$DetailMsg$` you can use number and wildcard options to indicate specific portions of the text string to include. For example: • `$DetailMsg$[5]` includes the fifth word of the detailed event message • `$ShortMsg$[1-5]` includes the first through fifth words of the short message event • `$DetailMsg$[*5]` includes the first through fifth words of the detailed event message • `$ShortMsg$[5*]` includes the fifth through last words of the short event message If you do not enter a word specifier, AppManager returns the entire string. The following are examples of the types of messages you can construct using these keywords: • Event from `$MachineName$`: The `$ShortMsg$[1-3]` has failed. The last command was `$DetailMsg$[4*]`. • A severity `$Severity$` event has occurred! Call the owner of `$MachineName$` immediately!

2.14 Messenger

Use this Knowledge Script to use the Windows Messenger service to send a message containing AppManager event information to a specified computer.

By default, the event information includes the computer name of the managed client and the event severity. You can select additional information to include.

You can also construct a custom message to send to recipients.

This script raises an event if you select the custom message format but neglect to enter any text for the custom message body. Under these circumstances, the script continues to execute and uses the standard message format.

The destination computer must be running the Windows Messenger service. To send the message to multiple computers, enter a comma-separated list of computer names.

NOTE:

- This Knowledge Script is not supported on Windows operating systems later than Windows Server 2003.
- If you are using this Knowledge Script to send a message from a Windows Server 2003 computer to a Windows NT 4 computer, the Messenger service must be running on both computers.

2.14.1 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Event Notification	
Event severity – Action warning	Set the severity level, from 1 to 40, to indicate the importance of an event in which the Messenger job returns a warning. The default is 35 (magenta event indicator).
Event severity – Action failure	Set the severity level, from 1 to 40, to indicate the importance of an event in which the Messenger job fails. The default is 5 (red event indicator).
Severity Configuration	
Minimum event severity for Action	Set the minimum severity level, from 1 to 40, for an event that triggers this Action. The default is 1.
Maximum event severity for Action	Set the maximum severity level, from 1 to 40, for an event that triggers this Action. The default is 40.
Action	
List of computers to receive message	Provide a computer name or click the Browse [...] button to select the recipient of the Messenger service message. To send a message to multiple recipients, enter a comma-separated list of computer names. For example: `QELAB,PORT1,Chris`. Each specified computer must be running the Messenger service.
Message format	Select whether you want to use the standard message format or create a custom message. The default is Standard. Use the Standard message format if you want the message text to be generated by the Knowledge Script. Use the Custom message format if you want to create your own message.

Parameter	How to Set It
Standard message options	
Include date/timestamp?	Select **Yes** to include the date and time of the event. The default is unselected.
Include JobID?	Select **Yes** to include the ID of the Knowledge Script job that raised the event. The default is unselected.
Include agent computer name?	Select **Yes** to include the name of the computer on which the event was raised. The default is Yes.
Include event severity?	Select **Yes** to include the event severity. The default is Yes.
Include Knowledge Script name?	Select **Yes** to include the name of the Knowledge Script that raised the event. The default is unselected.
Include AppManager object name?	Select **Yes** to include the name of the AppManager object where the event was raised. The default is unselected.
Include AppManager Event ID (only on MS action)?	Select **Yes** to include the event ID number when the Action is initiated by the AppManager management server. The default is unselected.
Include event detail message?	Select **Yes** to include the event detail message. The default is unselected.
Custom message options	

Parameter	How to Set It
Custom text (can include substitutions)	Provide the text you want to include in your custom message. You can use the keywords listed below to indicate the information you want to include in the body of your custom message. Add a space before and after keywords to ensure that the keywords display properly. • `$ShortMsg$` (short event message) • `$DetailMsg$` (detailed event message) • `$Time$` (date and time of the event) • `$JobID$` (ID of the job that raised the event) • `$MachineName$` (name of the computer where the event was raised) • `$Severity$` (severity of the event) • `$KSName$` (name of the Knowledge Script that raised the event) • `$ObjectName$` (name of the AppManager resource object where the event was raised) • `$EventID$` (event ID) For `$ShortMsg$` and `$DetailMsg$` you can use number and wildcard options to indicate specific portions of the text string to include. For example: • `$DetailMsg$[5]` includes the fifth word of the detailed event message • `$ShortMsg$[1-5]` includes the first through fifth words of the short message event • `$DetailMsg$[*5]` includes the first through fifth words of the detailed event message • `$ShortMsg$[5*]` includes the fifth through last words of the short event message If you do not enter a word specifier, AppManager returns the entire string. The following are examples of the types of messages you can construct using these keywords: • Event from `$MachineName$`: The `$ShortMsg$[1-3]` has failed. The last command was `$DetailMsg$[4*]`. • A severity `$Severity$` event has occurred! Call the owner of `$MachineName$` immediately!
Retry count	Set the number of time this script attempts to send the message. The default is 5.

2.15 NetAppFilerDoSnapMirror

Use this Knowledge Script to open a Telnet session on the specified Network Appliance filer and issue a `snapmirror` command. You should customize the command for your environment.

To issue a `snapmirror` command with no customization, use the NetAppFiler_DoSnapMirror Knowledge Script.

This Knowledge Script raises an event each time the Action runs. The event message displays the results of the `snapmirror` command.

TIP: A Network Appliance filer can have only one open Telnet session at a time. If a Telnet session is open when this Knowledge Script runs, the Knowledge Script job cannot issue the command and creates an event with a "Too Many Users" message. If this happens, you must wait for the next job iteration to detect the event condition and run this Action.

2.15.1 Setting Parameter Values

Set the following parameter as needed:

Parameter	How to Set It
Command to execute	Enter a Network Appliance filer non-interactive maintenance command. Enter a command as you would from a Telnet session. You do not need to enclose the command in quotation marks. The default is `snapmirror update`.

2.16 NetAppFilerIssueCommand

Use this Knowledge Script to open a Telnet session on the specified Network Appliance filer and issue a non-interactive maintenance command.

To simply issue a maintenance command, use the NetAppFiler_IssueCommand Knowledge Script.

This Knowledge Script does not support multi-line commands or interactive behavior.

This Knowledge Script raises an event each time the job runs. The event message displays the results of the maintenance command.

TIP: A Network Appliance filer can have only one open Telnet session at a time. If a Telnet session is open when this Knowledge Script runs, the Knowledge Script job cannot issue the command and creates an event with a "Too Many Users" message. If this happens, you must wait for the next job iteration to detect the event condition and run this Action.

2.16.1 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Command to execute	Specify the Network Appliance filer non-interactive maintenance command you want to execute. Enter a command as you would from a Telnet session. You do not need to enclose the command in quotation marks. The default, `?`, returns a list of all Network Appliance filer maintenance commands.

2.17 NetAppFilerReboot

Use this Knowledge Script to Telnet into a specified Network Appliance filer and issue a `reboot` command.

To only issue a `reboot` command, use the NetAppFiler_Reboot Knowledge Script.

This Knowledge Script raises an event each time the job runs. The event message displays the results of the `reboot` command.

TIP: A Network Appliance filer can have only one open Telnet session at a time. If a Telnet session is open when this Knowledge Script runs, the Knowledge Script job cannot issue the command and creates an event with a "Too Many Users" message. If this happens, you must wait for the next job iteration to detect the event condition and run this Action.

2.17.1 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Reboot filer?	Set to y to reboot the Network Appliance filer. To avoid an accidental reboot, the default is n.

2.18 NotesMail

Use this Knowledge Script to send a mail message containing AppManager event information to one or more Lotus Domino/Notes email users. To use this script, you must have a Domino Notes server, and the Notes server must be on the computer initiating the Action, either on the management server or on the managed client.

By default, the event information includes the computer name of the managed client and the event severity. You can select additional information to include.

You can also construct a custom message to send.

This script raises an event if you select the custom message format but neglect to enter any text for the custom message body. Under these circumstances, the script continues to execute and uses the standard message format.

2.18.1 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Event Notification	
Event severity – Action warning	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the NotesMail job returns a warning. The default is 35 (magenta event indicator).
Event severity – Action failure	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the NotesMail job fails. The default is 5 (red event indicator).
Severity Configuration	
Minimum event severity for Action	Set the minimum event severity level, from 1 to 40, for an event that triggers this Action. The default is 1.
Maximum event severity for Action	Set the maximum event severity level, from 1 to 40, for an event that triggers this Action. The default is 40.
Action	
List of recipients (comma-separated; form is "`user/company`")	Provide a list of recipients for the message, separated by commas (,) with no spaces, using the Notes username format (for example, `user/company`).
Sender name	Provide the mail sender name. It is displayed in the **From** field of the mail message that has the AppManager event information. The default is NetIQ AppManager.
Message format	Select the format you want to use for the message sent by this script: • **Standard** format generates a message based upon the selections you make from the *Standard message options* parameters. • **Custom** format generates a message based upon the subject and message body you supply in the *Custom message options* parameters. The default is Standard.
Standard message options	

Parameter	How to Set It
Include date/timestamp?	Select **Yes** to include the date/timestamp in the standard message. The default is unselected.
Include JobID?	Select **Yes** to include the job ID in the standard message. The default is unselected.
Include agent computer name?	Select **Yes** to include the name of the agent computer in the standard message (the computer hosting the agent that initiated the Action). The default is Yes.
Include event severity?	Select **Yes** to include the severity of the event in the standard message. The default is Yes.
Include Knowledge Script name?	Select **Yes** to include the Knowledge Script name in the standard message (the Knowledge Script that initiated the Action). The default is unselected.
Include AppManager object name?	Select **Yes** to include the AppManager resource object name in the standard message (the AppManager resource object where the event was raised). The default is unselected.
Include AppManager event ID (only on MS Action)?	Select **Yes** to include the AppManager event ID in the standard message (possible only in cases when the Action is carried out by the management server). The default is unselected.
Include event detail message?	Select **Yes** to include the event detail message. The default is unselected.
Custom message options	
Custom message subject	Provide the text you want to use for the custom message subject line.

Parameter	How to Set It
Custom message body	Provide the text you want to include in your custom message. You can use the keywords listed below to indicate the information you want to include in the body of your custom message. Add a space before and after keywords to ensure that the keywords display properly. • `$ShortMsg$` (short event message) • `$DetailMsg$` (detailed event message) • `$Time$` (date and time of the event) • `$JobID$` (ID of the job that raised the event) • `$MachineName$` (name of the computer where the event was raised) • `$Severity$` (severity of the event) • `$KSName$` (name of the Knowledge Script that raised the event) • `$ObjectName$` (name of the AppManager resource object where the event was raised) • `$EventID$` (event ID) For `$ShortMsg$` and `$DetailMsg$` you can use number and wildcard options to indicate specific portions of the text string to include. For example: • `$DetailMsg$[5]` includes the fifth word of the detailed event message • `$ShortMsg$[1-5]` includes the first through fifth words of the short message event • `$DetailMsg$[*5]` includes the first through fifth words of the detailed event message • `$ShortMsg$[5*]` includes the fifth through last words of the short event message If you do not enter a word specifier, AppManager returns the entire string. The following are examples of the types of messages you can construct using these keywords: • Event from `$MachineName$`: The `$ShortMsg$[1-3]` has failed. The last command was `$DetailMsg$[4*]`. • A severity `$Severity$` event has occurred! Call the owner of `$MachineName$` immediately!

2.19 NTEventLog

Use this Knowledge Script to write AppManager event information to the Windows event log. By default, the event is written to the Windows Application event log on the computer where the Action is initiated. You can select another event log where the event will be written, and you can select the event type: Error, Warning, or Information. You can also specify a custom event message or use the default message.

NOTE: This Action is performed on all physical nodes of a cluster when the NTEventLog Knowledge Script runs on a cluster server.

2.19.1 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Event Notification	
Event severity – Action warning	An event is raised when you select the custom message format but neglect to enter any text for the custom message body. Under these circumstances, the script continues to execute and uses the standard message format. Set the severity level, from 1 to 40, to indicate the importance of an event in which the NTEventLog job returns a warning. The default is 35 (magenta event indicator).
Event severity – Action failure	Set the severity level, from 1 to 40, to indicate the importance of an event in which the NTEventLog job fails. The default is 5 (red event indicator).
Severity Configuration	
Minimum event severity for Action	Set the minimum severity level, from 1 to 40, for an event that triggers this Action. The default is 1.
Maximum event severity for Action	Set the maximum severity level, from 1 to 40, for an event that triggers this Action. The default is 40.
Action	
Event log name	Select the log where the event message is written. The default is Application.
Event type	Select the type of event message. The default is Error.
Destination computer (leave blank for local computer)	Provide the name or IP address of the computer to whose log the event message is written. You can also click **Browse [...]** to select from a list of computers in the same domain as the agent computer.
Event source	Specify a name for the source of the event. The default is AppManager.
Event category	Specify a numerical identifier for the event category. Enter a number from 0 to 32766. The default is 0.
Event ID	Specify a numerical ID for the event. Enter a number from 0 to 65535. The default is 260.

Parameter	How to Set It
Message format	Select the format you want to use for the message sent by this script: • **Standard** format generates a message based upon the selections you make from the *Standard message options* parameters. • **Custom** format generates a message based upon the subject and message body you supply in the *Custom message options* parameters. The default is Standard.
Standard message options	
Include date/timestamp?	Select **Yes** to include the date/timestamp in the standard message. The default is unselected.
Include JobID?	Select **Yes** to include the job ID in the standard message. The default is unselected.
Include agent computer name?	Select **Yes** to include the name of the agent computer in the standard message (the computer hosting the agent that initiated the Action). The default is Yes.
Include event severity?	Select **Yes** to include the severity of the event in the standard message. The default is Yes.
Include Knowledge Script name?	Select **Yes** to include the Knowledge Script name in the standard message (the Knowledge Script that initiated the Action). The default is unselected.
Include AppManager object name?	Select **Yes** to include the AppManager resource object name in the standard message (the AppManager resource object where the event was raised). The default is unselected.
Include AppManager event ID (MS Action only)?	Select **Yes** to include the AppManager event ID in the standard message (possible only in cases when the Action is carried out by the management server). The default is unselected.
Include event detail message?	Select **Yes** to include the event detail message. The default is unselected.
Custom message options	

Parameter	How to Set It
Custom text (can include substitutions)	Provide the text you want to include in your custom message. You can use the keywords listed below to indicate the information you want to include in the body of your custom message. Add a space before and after keywords to ensure that the keywords display properly. • `$ShortMsg$` (short event message) • `$DetailMsg$` (detailed event message) • `$Time$` (date and time of the event) • `$JobID$` (ID of the job that raised the event) • `$MachineName$` (name of the computer where the event was raised) • `$Severity$` (severity of the event) • `$KSName$` (name of the Knowledge Script that raised the event) • `$ObjectName$` (name of the AppManager resource object where the event was raised) • `$EventID$` (event ID) For `$ShortMsg$` and `$DetailMsg$` you can use number and wildcard options to indicate specific portions of the text string to include. For example: • `$DetailMsg$[5]` includes the fifth word of the detailed event message • `$ShortMsg$[1-5]` includes the first through fifth words of the short message event • `$DetailMsg$[*5]` includes the first through fifth words of the detailed event message • `$ShortMsg$[5*]` includes the fifth through last words of the short event message If you do not enter a word specifier, AppManager returns the entire string. The following are examples of the types of messages you can construct using these keywords: • Event from `$MachineName$`: The `$ShortMsg$[1-3]` has failed. The last command was `$DetailMsg$[4*]`. • A severity `$Severity$` event has occurred! Call the owner of `$MachineName$` immediately!

2.20 Page

Use this Knowledge Script to send a paging call with AppManager event information to one or more recipients. Paging systems and target recipients (individuals or groups) are defined in the `\netiqpage.ini` file on the AppManager repository (QDB) computer. Before using this script, review and edit the `netiqpage.ini` file to identify the groups, phone numbers, and other parameters appropriate for your specific paging system.

By default, the event information includes the name of the agent computer and the event severity. You can select additional information to include.

You can also construct a custom message to send to recipients.

This script raises an event if you select the custom message format but neglect to enter any text for the custom message body. Under these circumstances, the script continues to execute and uses the standard message format.

2.20.1 Example of How this Script Is Used

Because each paging system has its own command-line syntax or API requirements, you need to define some information about the paging systems you are using in the `netiqpage.ini` file before using this Knowledge Script. The `netiqpage.ini` file specifies:

- Path to the paging server interface. For example, the path to the command-line program used to send the page.
- Command-line parameters or API syntax used to construct the page. For example, a specific paging interface may require a pager number, sender ID, or start time as command line arguments.
- Target group or profile names that contain the rules for contacting groups or individuals. For example, some paging systems allow an administrator to set up templates that define contact flow to control when specific groups can be reached by pager.

The following information is defined in the `netiqpage.ini` file in two sections:

- The `[system]` section, which defines the paging system, the path to the interface, and the command line parameters to be passed in from the `[group_name]` section depending on the *Name of the group to page* you enter in the Knowledge Script.
- The `[group_name]` sections, which define the details for target groups.

The following in an example of a `netiqpage.ini` file with definitions for three paging systems and two target groups, `QA` and `Sales`:

```
;;
;; sample netiqpage.ini file
;;
[system]
;; For the command line syntax for these paging systems:
;; first %s maps to the target_name [target]
;; second %s maps additional parameters [param]
;; third %s is the message passed in from the Knowledge Script
;;
attention=c:\AttnClient\attn -t %s %s %s
telalert=c:\usr\telalert\telalertc -c %s %s -m %s
hiplink=c:\hiplink\cms\hlclp -r:%s %s -m:'%s'  ;; msg in quotes
```

```
[QA]
    pageco1=hiplink
    target1=M
    param1=
    start_time1=00/00/00 00:00:00
    stop_time1=00/00/00 23:59:59
[Sales]
    pageco1=telalert
    target1=Pager
    param1= -n 4083031937
    start_time1=00/00/00 00:00:00
    stop_time1=00/00/00 23:59:59
    pageco2=telalert
    target2=Pager
    param2= -n 4083031937
    start_time2=5/12/98 00:00:00
    stop_time2=6/30/98 00:00:00
```

The Action_Page Knowledge Script uses the information defined in this file and the Action properties entered to construct the required command line to send the page. For example, if you set the *Name of the group to page* parameter to `Sales`, AppManager sends a page to the Sales pager number (`408-303-1937`) using the `telalert` paging system.

2.20.2 Defining a Paging Schedule

Within the `netiqpaqe.ini` file, you can set a paging start time and end time for each person or group. This allows you to define specific periods when the individuals in a group can be paged. For example, if you have a Tech Support group with two employees who can be paged any day of the week between the hours of midnight and 8:00 a.m. and one employee who can be paged at any hour during specific dates, you might create entries similar to the following in the `netiqpaqe.ini` file:

```
[TechSupport]
    pageco1=telalert
    target1=Blake                     // Blake can be paged
    param1= -n 4083031937             // between 12:00 a.m.
    start_time1=00/00/00 24:00:00     // and 8:00 a.m.
    stop_time1=00/00/00 08:00:00      // (no start date or
                                      // end date)
    pageco2=telalert
    target2=Andy                    // Andy has the same
    param2= -n 4084551037           // schedule as Blake
    start_time2=00/00/00 24:00:00
    stop_time2=00/00/00 08:00:00
    pageco3=telalert
    target3=Alex                    // Alex can be paged any
    param3= -n 4156542200           // hour from midnight
    start_time3=7/12/98 00:00:00    // July 12, 1998 until
    stop_time3=7/30/98 10:30:00     // 10:30a.m. July 30
```

Both the `start_time` and `stop_time` parameters consist of two parts—the date and time. If you do not want to specify a start date or an end date, set the first part of the appropriate parameter to `00/00/00` (as illustrated with `Blake` and `Andy` in the example above). If you do not want to specify a start time or an end time, set the second part of the appropriate parameter to `00:00:00` (as illustrated with `Alex` in the example).

You cannot use the `start_time` and `stop_time` parameters to set up weekly scheduling. You can only define scheduling profiles or templates using parameters associated with your paging system. For example, if your paging system supports a `-s schedule_profile` command-line parameter, you can include this in the netiqpaqe.ini file as you do other parameters. For example:

```
[system]
page_app=c:\PageSysClient\sendpage -t %s -n %s %s -m %s
[WeekdayCrew]
    pageco1=page_app
    target1=scott
    param1= -n 4083031937 -s weekday_profile
                          // name of a template that
                          // allows paging Mon-Fri
    start_time1=00/00/00 00:00:00
    stop_time1=00/00/00 00:00:00
```

2.20.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Event Notification	
Event severity – Action warning	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the Page job returns a warning. The default is 35 (magenta event indicator).
Event severity – Action failure	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the Page job fails.
Severity Configuration	
Minimum event severity for Action	Set the minimum severity level, from 1 to 40, for an event that triggers this Action. The default is 1.
Maximum event severity for Action	Set the maximum severity level, from 1 to 40, for an event that triggers this Action. The default is 40.
Action	
Name of the group to page (in netiqpage.ini)	Provide the name of the individual or group to receive this page. Valid names are the [group_name] sections you defined in the `netiqpage.ini` file.
Send a test page to a file?	Select **Yes** to send a test page to a file. The default is unselected.
Full path to test page file	Provide the full path to the file where you want to send your test page. The default is `c:\page.log`.
Message format	Select whether you want to use the standard message or create a custom message. The default is Standard. Use the Standard message format if you want the message text to be generated by the Knowledge Script. Use the Custom message format if you want to create your own message.
Standard Message Options	
Include date/timestamp?	Select **Yes** to include the date and time of the event. The default is unselected.

Parameter	How to Set It
Include JobID?	Select **Yes** to include the ID of the Knowledge Script job that raised the event. The default is unselected.
Include agent computer name?	Select **Yes** to include the name of the computer on which the event was raised. The default is Yes.
Include event severity?	Select **Yes** to include the event severity with the page. The default is Yes.
Include Knowledge Script name?	Select **Yes** to include the name of the Knowledge Script that raised the event. The default is unselected.
Include AppManager object name?	Select **Yes** to include the name of the AppManager object where the event was raised. The default is unselected.
Include AppManager event ID (MS Action only)?	Select **Yes** to include the event ID number when the Action is initiated by the AppManager management server. The default is unselected.
Include event detail message?	Select **Yes** to include the text of the event detail message with the page. The default is unselected.
Custom Message Options	
Custom message	Provide the message, up to 255 characters, you want to send with the page. If you do not specify a message, AppManager constructs a default message including the name of the agent computer and the severity level of the event.

2.21 RebootSystem

Use this Knowledge Script to shut down and restart a computer when an event is raised. This Action can run only on the managed computer as a Managed Client Action; select *Managed Client Action* in the Knowledge Script Properties dialog box.

To run this Knowledge Script, you need to be identified as a user with administrator privileges or have been granted permission to use this Action by the AppManager administrator.

This Knowledge Script also requires a registry setting under `HKEY_LOCAL_MACHINE\Software`: `NetIQ\AppManager\4.0\NetIQmc\Security`.

By default, the `AllowReboot` registry key is set to `null` to prevent *any* management servers from rebooting clients. If you have administrative privileges, you can change the registry settings to specify individual management servers or all management servers (using the wildcard *). For example: `AllowReboot:REG_SZ:mktg02;salesNA;190.12.1.28`.

You can use the NTAdmin_RegistrySet Knowledge Script to modify the registry key with the appropriate management server computer names.

Because of an Exchange mechanism, this Knowledge Script takes some time to reboot a computer if any Exchange service is running on that computer. Before using this Action, check whether any Exchange service is running on the target computers. If any Exchange service is running:

- Consider stopping the service before starting a Knowledge Script job that uses this Action.
- Consider whether you want to use this Action Knowledge on the selected computer.
- Allow for a longer-than-normal shutdown and reboot period.

2.21.1 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Restart computer after shutdown?	Set to y to automatically restart the computer after shutting down. The default is y.
Force applications with unsaved changes to be closed?	Set to y to force any open applications to close when shutting down. In most cases, unsaved changes will be lost. The default is y.
Message to be displayed in the shutdown dialog box	Provide the message you want displayed in the shutdown dialog box. For example, if you are forcing applications to close, you may want the shutdown message to include a warning that unsaved changes may be lost.
Number of seconds to display shutdown dialog box	Specify the number of seconds you want the shutdown dialog displayed. The default is 60 seconds.
Number of hours to wait between restarts	Specify the number of hours to wait after the last restart before attempting another reboot. This parameter allows you to prevent the Knowledge Script job from continuously shutting down and rebooting a computer. The default is 4 hours.
Event severity	Set the event severity level, from 1 to 40, to indicate the importance of the event when this Action Knowledge Script encounters problems in shutting down or restarting the computer. The default is 7 (red event indicator).

2.22 RestartServices

Use this Knowledge Script to stop and restart Windows services. Enter the services you want to stop and restart as a comma-separated list.

Enable the *Restart dependent services?* parameter to restart services that depend on the ones you stopped. By default, this script restarts dependent services.

2.22.1 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Event Notification	
Event severity – Job failure	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the RestartServices job fails. The default is 10 (red event indicator).
Severity Configuration	
Minimum event severity for Action	Set the minimum severity level, from 1 to 40, for an event that triggers this Action. The default is 1.
Maximum event severity for Action	Set the maximum severity level, from 1 to 40, for an event that triggers this Action. The default is 40.
Action	
List of services (comma-separated, no spaces)	Provide a comma-separated list of the services you want to stop and restart.
Service start/stop delay	Set the number of seconds to wait between stopping and restarting a service. The default is 30.
Restart dependent services?	Select **Yes** to restart services that depend on the ones you stopped. The default is Yes. For example, if you stop the `MSSQLSERVER` service, the dependent service `SQLSERVERAGENT` is also stopped. If you select **Yes**, the `MSSQLSERVER` service will be restarted, and then the `SQLSERVERAGENT` service will also be restated. If you clear this check box, any dependent services of the service you specified are stopped and not restarted.

2.23 RunDiscoveryCiscoCallMgr

Use this Knowledge Script to discover Cisco Unified Communication Manager resources as a result of an event raised by the CiscoCallMgr_CCM_RoleStatus Knowledge Script.

In the event of a failover from a Primary CallManager to a Backup Communication Manager, you can set the Actions tab of the CCM_RoleStatus script to run RunDiscoveryCiscoCallMgr. This Action discovers Communication Manager resources on the Backup computer and, if you have configured a monitoring policy to do so, any jobs that are running on the Primary computer will be transferred to the Backup Communication Manager.

2.23.1 Prerequisite

NetIQ Object Linking and Embedding (`NetIQOLE`) must be registered on the computer on which this script runs. `NetIQOLE` is an automation object that allows AppManager to be run from a command-line. For more information, see the *Administrator Guide for AppManager* at the NetIQ AppManager Documentation Web site.

2.23.2 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
View name to use for Knowledge Script filter	Select the view by which you want to filter the list of Knowledge Scripts to choose from. For example, select Master to include all Knowledge Scripts.
Show REPORTAM Knowledge scripts?	Set to y to include Report scripts in the list of scripts to choose from.
Show Discovery Knowledge scripts?	Set to y to include Discovery scripts in the list of scripts to choose from.
Show AMAdmin Knowledge scripts?	Set to y to include Admin scripts in the list of scripts to choose from.
First Knowledge Script to run	From the filtered list of Knowledge Scripts, select the first script that you want to run in response to an error. The script will run using all of the default parameter values unless you select and enter information in *Parameter to pass* and *Values for parameters*.
Parameter to pass	Provide a comma-separated list of the parameters whose default values you want to change. Leave this field blank if you want to use the default values. If you select parameters in this field, you must also enter values in *Values for parameters*.
Values for parameters	Provide a comma-separated list of the values for the parameters that you want to change. For example, enter `y,y,20`. Leave this field blank if you leave *Parameters to pass* blank.
Second Knowledge Script to run	From the filtered list of Knowledge Scripts, select the second script that you want to run in response to an error. The script will run using all of the default parameter values unless you select and enter information in *Parameter to pass* and *Values for parameters*.
Parameters to pass	Provide a comma-separated list of the parameters whose default values you want to change. Leave this field blank if you want to use the default values. If you select parameters in this field, you must also enter values in *Values for parameters*.

Parameter	How to Set It
Values for parameters	Provide a comma-separated list of the values for the parameters that you want to change. For example, enter `y,y,20`. Leave this field blank if you leave *Parameters to pass* blank.
Third Knowledge Script to run	From the filtered list of Knowledge Scripts, select the third script that you want to run in response to an error. The script will run using all of the default parameter values unless you select and enter information in *Parameter to pass* and *Values for parameters*.
Parameters to pass	Provide a comma-separated list of the parameters whose default values you want to change. Leave this field blank if you want to use the default values. If you select parameters in this field, you must also enter values in *Values for parameters*.
Values for parameters	Provide a comma-separated lis of the values for the parameters that you want to change. For example, enter `y,y,20`. Leave this field blank if you leave *Parameters to pass* blank.
Use trusted connection?	Set to y to use the credentials of the `netiqmc` service to connect to the repository server. The default is n. If you accept the default, then you must enter a *User ID* and *Password*.
QDB Server	Specify the name of the repository server. Leave this field blank if the repository server is the local server.
QDB Database	Specify the name of the AppManager repository that manages Knowledge Script jobs. Leave this field blank to use the default repository name, `QDB`.
User ID	Specify the user ID for a non-trusted connection to the repository server. You must enter a user ID if you disabled the *Use trusted connection?* parameter.
Password	Specify the password for a non-trusted connection to the repository server. You must enter a password if you disabled the *Use trusted connection?* parameter.
Run this Knowledge Script once	Set to y to schedule this script to run once, overriding the default schedule of the scripts you selected. If you disable this parameter, the scripts you selected will run according to the default.
Machine to run Knowledge Script on	Specify the name of the server on which you want to run the scripts you selected. Leave this field blank if the server is the same as the server of the parent job that raised the event.

2.24 RunDiscoveryNetworkDevice

Use this Knowledge Script to discover network device resources as a result of an event raised by the NetworkDevice_Device_Uptime Knowledge Script.

In the event of a network device reboot, you can set the Device_Uptime Knowledge Script to run this Action to rediscover network device resources on the rebooted device.

2.24.1 Prerequisite

NetIQ Object Linking and Embedding (`NetIQOLE`) must be registered on the computer on which this script runs. `NetIQOLE` is an automation object that allows AppManager to be run from a command-line. For more information, see the *Administrator Guide for AppManager* at the NetIQ AppManager Documentation Web site.

2.24.2 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
View name to use for KS filter	Select the view by which you want to filter the list of Knowledge Scripts to choose from. For example, select Master to include all Knowledge Scripts.
Show Report scripts?	Set to y to include Report scripts in the list of scripts to choose from.
Show Discovery scripts?	Set to y to include Discovery scripts in the list of scripts to choose from.
Show Admin scripts?	Set to y to include Admin scripts in the list of scripts to choose from.
First KS to run	From the filtered list of Knowledge Scripts, select the first script that you want to run in response to an error. The script will run using all of the default parameter values unless you select and enter information in the *Parameter to pass* and *Values for parameters* parameters.
Parameter to pass	Select the parameters whose default values you want to change. Leave this field blank if you want to use the default values. If you select parameters in this field, you must also enter values for the *Values for parameters* parameter.
Values for parameters	Specify the values for the parameters that you want to change. Separate the values with a comma. For example, enter `y,y,20`. Leave this field blank if you leave *Parameters to pass* blank.
Second KS to run	From the filtered list of Knowledge Scripts, select the second script that you want to run in response to an error. The script will run using all of the default parameter values unless you select and enter information for *Parameter to pass* and *Values for parameters*.
Parameters to pass	Select the parameters whose default values you want to change. Leave this field blank if you want to use the default values. If you select parameters in this field, you must then enter values for the *Values for parameters* parameter.
Values for parameters	Enter the values for the parameters that you want to change. Separate the values with a comma. For example, enter `y,y,20`. Leave this field blank if you leave the *Parameters to pass* parameter blank.

Parameter	How to Set It
Third KS to run	From the filtered list of Knowledge Scripts, select the third script that you want to run in response to an error. The script will run using all of the default parameter values unless you select and enter information for *Parameter to pass* and *Values for parameters*.
Parameters to pass	Select the parameters whose default values you want to change. Leave this field blank if you want to use the default values. If you select parameters in this field, you must also enter values for the *Values for parameters* parameter.
Values for parameters	Specify the values for the parameters that you want to change. Separate the values with a comma. For example, enter `y,y,20`. Leave this field blank if you leave *Parameters to pass* blank.
Use trusted connection?	Set to y to use the credentials of the `netiqmc` service to connect to the repository server. The default is n. If you accept the default, then you must enter a *User ID* and *Password*.
QDB Server	Specify the name of the repository server. Leave this field blank if the repository server is the local server.
User ID	Specify the user id for an un-trusted connection to the repository server. You must enter a user ID if you disable the *Use trusted connection?* parameter.
Password	Specify the password for an un-trusted connection to the repository server. You must enter a password if you disable the *Use trusted connection?* parameter.
Run this KS once	Set to y to schedule this script to run once, thereby overriding the default schedule of the scripts you have selected. If you disable this parameter, the scripts you selected will run according to the default.
Machine to run KS on	Specify the name of the server on which you want to run the scripts you selected. Leave this field blank if the server is the same as the server of the parent job that raised the event.

2.25 RunKS

Use this Knowledge Script to run up to three other Knowledge Scripts. You can also specify parameter settings for the Knowledge Scripts if you do not want to use the default settings.

This script uses the login credentials of the `NetIQmc` service (the AppManager agent) on the management server computer.

2.25.1 Prerequisite

NetIQ Object Linking and Embedding (`NetIQOLE`) must be registered on the computer on which this script runs. `NetIQOLE` is an automation object that allows AppManager to be run from a command-line. For more information, see the *Administrator Guide for AppManager* at the NetIQ AppManager Documentation Web site.

2.25.2 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Event Notification	
Event severity – Action failure	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the RunKS job fails. The default is 5 (red event indicator).
Severity Configuration	
Minimum event severity for Action	Set the minimum severity level, from 1 to 40, for an event that triggers this Action. The default is 1.
Maximum event severity for Action	Set the maximum severity level, from 1 to 40, for an event that triggers this Action. The default is 40.
Action	
Knowledge Script Configurations	
View name to use for Knowledge Script filter	Select an Operator Console view and computer by which you can filter the list of available Knowledge Scripts. The default is Master. Selecting an Operator Console view limits the list of available Knowledge Scripts to those visible in that view. Selecting a computer further limits the list of available Knowledge Scripts to ones that can run on that computer.
Show Report scripts?	Select **Yes** to include Report scripts in the list of available Knowledge Scripts. The default is unselected.
Show Discovery scripts?	Select **Yes** to include Discovery scripts in the list of available Knowledge Scripts. The default is unselected.
Show Administrator scripts?	Select **Yes** to include all Administrator scripts (for example, AMAdmin scripts), in the list of available Knowledge Scripts. The default is unselected.
First Knowledge Script to run	Select the first Knowledge Script run by this Action script.

Parameter	How to Set It
Parameters to pass (comma-separated)	Select the parameters whose default settings you want to change (for example, a different threshold value). To change the parameters you selected, select **CLEAR SELECTION** in the Select a Parameter dialog box, then click **Finish**. Once AppManager clears the previous parameters, click Browse [...] again and select new parameters for which you want to change the default settings. The browser for selecting parameters lists both the parameter name as it appears in the code for the script (for example, `TH_Physical`) and the description of the parameter as it appears in the Values tab of the Knowledge Script Properties dialog box (for example, `Maximum physical memory threshold`).

Values for parameters (comma-separated)	Provide a comma-separated list of the values for the parameters you have selected in an order that mirrors the parameter selection.
	
	For example, if you selected the following threshold parameters from NT_MemUtil for monitoring memory use:
	
	`TH_Physical,TH_Virtual,TH_Paging`
	
	then you would enter their values as follows:
	
	`95,95,95`
	
	NOTE: The value you enter must be in the format expected by the Knowledge Script. For example:
	• If the possible values for a parameter are numbers from 0-100, you must enter a number in that range.
	• If the possible values are `y` or `n`, then you must enter `y` or `n`.
	
	One exception to this is where a Knowledge Script uses a selected check box to specify a **Yes** value and a cleared check box to specify a **No** value. In this case, the underlying values are `y` or `n`, and you must enter `y` or `n`.

Second Knowledge Script to run	Select a second Knowledge Script run by this Action script.
Parameters to pass (comma-separated)	Select the parameters whose default settings you want to change (for example, a different threshold value). To change the parameters you selected, select **CLEAR SELECTION** in the Select a Parameter dialog box, then click **Finish**. Once AppManager clears the previous parameters, click Browse [...] again and select new parameters for which you want to change the default settings. The browser for selecting parameters lists both the parameter name as it appears in the code for the script (for example, `TH_Physical`) and the description of the parameter as it appears in the Values tab of the Knowledge Script Properties dialog box (for example, `Maximum physical memory threshold`).

Parameter	How to Set It

Values for parameters (comma-separated)	Provide a comma-separated list of the values for the parameters you have selected in an order that mirrors the parameter selection.
	
	For example, if you selected the following threshold parameters from NT_MemUtil for monitoring memory use:
	
	`TH_Physical,TH_Virtual,TH_Paging`
	
	then you would enter their values as follows:
	
	`95,95,95`
	
	NOTE: The value you enter must be in the format expected by the Knowledge Script. For example:
	• If the possible values for a parameter are numbers from 0-100, you must enter a number in that range.
	• If the possible values are `y` or `n`, then you must enter `y` or `n`.
	
	One exception to this is where a Knowledge Script uses a selected check box to specify a **Yes** value and a cleared check box to specify a **No** value. In this case, the underlying values are `y` or `n`, and you must enter `y` or `n`.

Third KS to run	Select a third Knowledge Script run by this Action script.
Parameters to pass (comma-separated)	Select the parameters whose default settings you want to change (for example, a different threshold value). To change the parameters you selected, select **CLEAR SELECTION** in the Select A Parameter dialog box, then click **Finish**. Once AppManager clears the previous parameters, click Browse [...] again and select new parameters for which you want to change the default settings. The browser for selecting parameters lists both the parameter name as it appears in the code for the script (for example, `TH_Physical`) and the description of the parameter as it appears on the **Values** tab of the Knowledge Script Properties dialog box (for example, `Maximum physical memory threshold`).

Values for parameters (comma-separated)	Provide a comma-separated list of the values for the parameters you have selected in an order that mirrors the parameter selection.
	
	For example, if you selected the following threshold parameters from NT_MemUtil for monitoring memory use:
	
	`TH_Physical,TH_Virtual,TH_Paging`
	
	then you would enter their values as follows:
	
	`95,95,95`
	
	NOTE: The value you enter must be in the format expected by the Knowledge Script. For example:
	• If the possible values for a parameter are numbers from 0-100, you must enter a number in that range.
	• If the possible values are `y` or `n`, then you must enter `y` or `n`.
	
	One exception to this is where a Knowledge Script uses a selected check box to specify a **Yes** value and a cleared check box to specify a **No** value. In this case, the underlying values are `y` or `n`, and you must enter `y` or `n`.

Run this Knowledge Script once (override default schedule)?	Select **Yes** to run the specified Knowledge Scripts only once regardless of their default schedules. The default is Yes.

Parameter	How to Set It
Computer to run Knowledge Script (leave blank for same as parent job)	Specify the name of the computer on which the Knowledge Scripts will run, or click **Browse [...]** to select a computer in the Computer Browser dialog box. If you leave this parameter blank, the scripts will run on the same computer as the Knowledge Script that initiated the Action.
AppManager Repository Configuration	
Use trusted connection?	Select **Yes** to use a trusted connection when running the Knowledge Scripts. The default is Yes. If you use a trusted connection, the Knowledge Scripts run under the logon account used by the `netiqmc` service on the computer running the Knowledge Script that initiated the Action. If you do not use a trusted connection, the Knowledge Scripts run with the username and password specified in the parameters below.a
Repository server (blank for local server)	Provide the name of the SQL Server used for the AppManager repository that will manage the Knowledge Script jobs. If you leave this value blank, the local computer name is used (the local computer is the one running the Knowledge Script that initiated the Action).
Repository database (blank if name is QDB)	Provide the name of the AppManager repository that will manage the Knowledge Script jobs. If you leave this value blank, the default repository name, `QDB`, is used.
User ID (non-trusted connection)	Provide the username for the account under which the Knowledge Scripts will run (if you disabled the *Use trusted connection?* parameter).
Password (non-trusted connection)	Provide the password for the account under which the Knowledge Scripts will run (if you disabled the *Use trusted connection?* parameter).

2.26 RunPhoneInventory

Use this Knowledge Script to produce an inventory of phones on a Cisco Unified Communication Manager Publisher.

This Action launches the CiscoCallMgr_CCM_PhoneInventory Knowledge Script on the Publisher associated with the server on which you are running the CiscoCallMgr_LossOfHardwarePhones Knowledge Script. Use the Actions tab on LossOfHardwarePhones to configure RunPhoneInventory.

The inventory results file is written on the computer where the AppManager agent is running, which is the Communication Manager Publisher.

This Action can invoke CCM_PhoneInventory only on repository computers (remote or local) that successfully communicate using Windows Authentication (a trusted connection).

2.26.1 Prerequisite

NetIQ Object Linking and Embedding (`NetIQOLE`) must be registered on the computer on which this script runs. `NetIQOLE` is an automation object that allows AppManager to be run from a command-line. For more information, see the *Administrator Guide for AppManager* at the NetIQ AppManager Documentation Web site.

2.26.2 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Event Notification	
Severity - Action warning	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the RunPhoneInventory job returns a warning. The default is 35.
Severity - Action failure	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the RunPhoneInventory job fails, such as an inability to write to the file or access the database. The default is 5.
Severity Configuration	
Minimum event severity for Action	Set the minimum severity level, from 1 to 40, for an event that triggers this Action. The default is 1.
Maximum event severity for Action	Set the maximum severity level, from 1 to 40, for an event that triggers this Action. The default is 40.
Phone Inventory Script Configuration	
CallManager database user name	Specify the user login account that you want to use to access the Communication Manager SQL Server database. Leave this field blank to use Windows authentication.
Search Options	

Parameter	How to Set It
Select by	Choose the criteria that you want to use to create the list of phones. • Name (the default) • DirectoryNumber • Description • DevicePool • CallingSearchSpace • Partition • Subnet. If you select this option, then you must enter the subnet address in the *Selection criteria* parameter. Use the following syntax: `172.16.10.0/20`. • SubnetFilepath. If you select this option, then, in the *Selection criteria* parameter, provide the UNC or full path to a file that contains a list of subnet specifications.
Selection criteria	Specify the selection criteria for the phones to be listed. Specify the actual item or specify a pattern by using the * wildcard. For example, to monitor all the phones with device names that begin with SEP, enter `SEP*`. To specify multiple items, separate each item with a comma. For example: `SEP0009A*,SEP0009B*` The items you list must be of the same type as the *Select by* parameter. So if *Select by* is Name, then the items you list must be device names or patterns. If *Select by* is DirectoryNumber, then the items you list must be directory numbers or patterns.
Order by	Select **Name** to display the contents of the results file in order by the phone name. The default is Name. Select **DirectoryNumber** to display the contents of the results file in order by directory numbers. Select **Subnet** to display the contents of the results file in order by subnet number.
Full path to results file	Specify the full path or a UNC path to which the inventory `.csv` file should be written. The default path is `c:\Program Files\NetIQ\Temp\NetIQ_Debug\PhoneInventory.csv`
AppManager Repository Configuration	
QDB Server	Specify the name of the SQL Server used for the AppManager repository that will manage the Knowledge Script jobs. If you leave this value blank, the local computer name is used (the local computer is the one running the Knowledge Script that initiated the Action).
QDB Database	Specify the name of the AppManager repository that manages Knowledge Script jobs. If you leave this value blank, the default repository name, `QDB`, is used.

2.27 RunPowerShell

Use this Knowledge Script to run a non-interactive Microsoft Windows PowerShell cmdlet or PowerShell script (`.PS1` file) when an event is raised by another Knowledge Script. You can also use this script to run any command that can be run from a Windows PowerShell command prompt, such as `dir c:\temp`. PowerShell accepts commands in cmdlet, `.PS1`, and Windows `cmd.exe` formats.

The Action_RunPowerShell script makes a number of callback and helper functions available to the PowerShell commands or scripts being run. For more information, see Appendix A, "Using PowerShell Callback and Helper Functions" in the management guide.

2.27.1 Prerequisites

- Microsoft Windows PowerShell version 1.0 or later
- Microsoft .NET Framework 3.0 or later
- AppManager for Windows version 7.6 or later

2.27.2 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Event Notification	
Severity - Action failure	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the RunPowerShell job fails. The default is 5.
Severity Configuration	
Minimum event severity for Action	Set the minimum severity level, from 1 to 40, for an event that triggers this Action Knowledge Script. The default is 1.
Maximum event severity for Action	Set the maximum severity level, from 1 to 40, for an event that triggers this Action Knowledge Script. The default is 40.
Action	

Parameter	How to Set It

PowerShell scripts, cmdlets, or code blocks to execute	Provide the PowerShell scripts, cmdlets, or code blocks you want to run. Do not provide a command that requires user input. The command should take care of any required input and output redirection or handling. You can string multiple commands together. You can use the following keywords in a command:
	• `$ShortMsg$` (short event message)
	• `$DetailMsg$` (detailed event message)
	• `$Time$` (date and time of the event)
	• `$JobID$` (ID of the job that raised the event)
	• `$MachineName$` (name of the computer where the event was raised)
	• `$Severity$` (severity of the event)
	• `$KSName$` (name of the Knowledge Script that raised the event)
	• `$ObjectName$` (name of the AppManager resource object where the event was raised)
	• `$EventID$` (event ID)
	For `$ShortMsg$` and `$DetailMsg$`, you can use number and wildcard options to indicate specific portions of a text string to include. If you do not include an option, AppManager returns the entire text string. For example:
	• `$DetailMsg$[5]` includes the fifth word of the detailed event message
	• `$ShortMsg$[1-5]` includes the first through fifth words of the short event message
	• `$DetailMsg$[*5]` includes the first through fifth words of the detailed event message
	• `$ShortMsg$[5*]` includes the fifth through last words of the short event message
	For example, the following string runs the `echo` command in PowerShell and prints the detailed event information, starting from the eighth word, into the `log.txt` file on the agent computer:
	`Echo $DetailMsg$[8*] > c:\temp\log.txt`
	Hint If the command you are entering includes quotation marks (“), enclose the quoted string within a second set of quotation marks. For example:
	`Send-MailMessage -From me@mycompany.com -To you@yourcompany.com -Subject ""Hello!"" -SmtpServer smtp.mycompany.com`

2.28 RunSql

Use this Knowledge Script to run SQL statements or stored procedures. You can enter the SQL statements to run, or you can supply the full path to a file from which to load SQL statements.

2.28.1 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if SQL statement succeeds?	Set to y to raise an event when the SQL statement is successful. The default is y. An event is always raised if an error occurs.
SQL Server name and instance if applicable ("SQL\Instance")	You can specify a SQL Server or a SQL Server and a named instance. Use the form "`SQL\Instance`". By default, the default SQL Server instance on the computer where the Action runs is used.
SQL login	Specify the database user account that will run the SQL statements (for example, `sa)`. However, it is also possible to run this Knowledge Script using other user accounts that have been set up in the SQL Server of the managed client and been given permission to run SQL Knowledge Scripts through AppManager Security Manager. **NOTE:** In general, permission to run specific SQL commands and statements is derived from the permissions granted to the login account you are using to run this Knowledge Script. However, the dbcc command can only be run by: • `dbo` account (SQL Server 6.x or 7) • `db_backup operator` account (SQL Server 7)
Load SQL script from a file?	Set to y to have SQL statements read from a file. Set to **n** to enter the SQL statements in the SQL Statements field. The default is n.
Full path to SQL script file	If you are entering SQL statements from a file, provide the complete file path (for example, `F:\netiq\Sample.sql`). If the NetIQmc service is running as a system account, do not provide a path in the form of `\\machine\dir\Sample.sql`
SQL statement	Specify the T-SQL statement to be executed. The default is `sp_who2`. **Tip** Unless you are entering very simple queries, typing SQL statements into this field may be error-prone. Use the *Load SQL Script from a file* parameter to read T-SQL statements from a file. Or, if you have an AppManager Developer's license, you can check the Knowledge Script out of the repository, use the script editor to paste the desired SQL statements into the SQL Statement field, then check the modified Knowledge Script back in.
Save query results to a file?	Set to y to save query results to an external file. The default is n. **NOTE:** Only the first 100 lines are written to the external file.
Full path to results file	Specify a full path to the file where you want query results saved.
Severity when SQL Statement fails	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the SQL statement fails to run. The default is 10 (red event indicator).

Parameter	How to Set It
Severity when SQL Statement succeeds	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the SQL statement runs successfully. The default is 20 (yellow event indicator).

2.29 SendReportToPrinter

Use this Knowledge Script to send a report to the printer that acts as the default printer for the managed client computer where the Report agent is running.

When running this script, consider the following:

- Install the Report agent and the Windows Management Server on the same computer.
- On the computer where the Report agent is installed, configure the managed client to run as `user`. Ensure that this user account has a default printer configured.
- Configure the `URLMapping` registry key to change the default output path of the Report agent to `<hostname>\AMReports\report`. Use the AMAdmin_SetReportPaths Knowledge Script to change the output path.

  NOTE: You can also manually configure the output path of the Report agent. At a command prompt, enter regedit. In the Registry Editor window, navigate to `NetIQ\Common\AMREPORTS`. In the right panel, right-click on **URLMapping** and select **Modify**. In the Edit String dialog box, enter `<hostname>\AMReports\report` in the **Value data** field, then click **OK**.

- To use this Action when you are configuring report properties, click the Action tab, click New, select SendReportToPrinter, and then change the Location to MC.

2.29.1 Configuring the Managed Client to Run As User

Before you can use SendReportToPrinter, you must create a user for the NetIQ Client Resource Monitor (`NetIQmc`, also called the managed client) service on the computer where the Report agent is installed. The log-on type for this service is probably `LocalSystem` — but you cannot enable the printer function from a `LocalSystem` logon account.

To create a user for the managed client:

1. From the Windows Control Panel of the computer you want to configure, double-click Administrative Tools, and then double-click Services.
2. Right-click NetIQ AppManager Client Resource Monitor, and select Properties.
3. Click the Logon tab. If `Local System account` is selected, select This account and enter your user ID and password in the appropriate fields.
4. Ensure the user ID and password have permission to access the AppManager repository.
5. Click OK. In the Services window, notice that the **Logon As** information for NetIQ AppManager Client Resource Monitor has changed from `LocalSystem` to your username.
6. In the Services window, right-click NetIQ AppManager Client Resource Monitor and select Restart. Once the service stops and restarts, it is ready to accept printer requests.

2.29.2 Using SendReportToPrinter to Print a PDF

You can use the SendReportToPrinter Action to print your report as a `PDF` (Portable Document Format) file. You must have PDF conversion software installed on the Report agent computer.

To print a report as a PDF:

1. Install your PDF conversion software on the Report agent computer. Refer to your PDF software documentation for details about installation and preferences.
2. On the Report agent computer, set the PDF computer as the default printer.
3. Configure your report properties.
4. On the Action tab, click **New**, select **SendReportToPrinter**, and then change **Location** to **MC**.
5. Generate your report. Look for the PDF in the default location specified by your conversion software.

2.29.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if job succeeds?	Set to y to raise an event if the process is successful. The default is n.
Event severity when...	Set the event severity level, from 1 to 40, to indicate the importance of the event when: • ... job succeeds. The default is 25 (blue event indicator). • **... job fails**. The default is 5 (red event indicator).

2.30 SMTPMail

Use this Knowledge Script to send an SMTP mail message with AppManager event information to a list of one or more mail recipients.

By default, the event information includes the computer name of the monitored computer and the event severity. You can include additional information by enabling the appropriate parameters.

To override the default subject and body for the email message, select *Custom Message Options* parameters.

This script raises an event if you select the custom message format but neglect to enter any text for the body of the custom message. Under these circumstances, the script continues to run using the standard message format.

NOTE: The event ID is not included in the default message when this Action runs on a managed client (MC) computer.

2.30.1 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Event Notification	
Raise event if SMTP server is not accessible?	Select **Yes** to raise an event if the SMTP server cannot be reached. The default is Yes.
Event severity – SMTP server not accessible	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the SMTP server cannot be reached. The default is 35 (magenta event indicator).
Event severity – Action failure	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the SMTPMail job fails. The default is 5 (red event indicator).
Severity Configuration	
Minimum event severity for Action	Specify the minimum severity level, from 1 to 40, for an event that triggers this Action. The default is 1.
Maximum event severity for Action	Specify the maximum severity level, from 1 to 40, for an event that triggers this Action. The default is 40.
Action	
List of recipient email addresses	Provide the full email address for each recipient of the message. Use semicolons (;) to separate multiple recipient addresses. For example: `chris@abc.com;pat@def.com;jw@abc.com`. **NOTE:** The following characters are invalid in this parameter: `/ \ [ ] : | = , * ? < >`
Sender's email address	Provide the email address of the person sending the message. **Notes** • In Microsoft Exchange Server 2007 environments, specify the sender name in SMTP format: `<name>@<domain>`. • The following characters are invalid in this parameter: `/ \ [ ] : | = , * ? < >`

Parameter	How to Set It
SMTP server name	Provide the host name or IP address of your SMTP server. The default is `inet01`.
SMTP port	Set the port number for your SMTP server. The default is 25.
Message format	Select the format you want to use for the message sent by this script: • **Standard** format generates a message based upon the selections you make from the *Standard message options* parameters. • **Custom** format generates a message based upon the subject and message body you supply in the *Custom message options* parameters. The default is Standard.
Ping SMTP server before sending mail message?	Select **Yes** to ping the SMTP server to verify TCP connectivity before attempting to send an email to your listed recipients. The default is Yes.
Standard Message Options	
Include date/timestamp?	Select **Yes** to include the date/timestamp in the standard message. The default is unselected.
Include JobID?	Select **Yes** to include the job ID in the standard message. The default is unselected.
Include agent computer name?	Select **Yes** to include the name of the agent computer that initiated the Action in the standard message. The default is Yes.
Include event severity?	Select **Yes** to include the severity of the event in the standard message. The default is Yes.
Include Knowledge Script name?	Select **Yes** to include the name of the Knowledge Script that initiated the Action in the standard message. The default is unselected.
Include AppManager object name?	Select **Yes** to include the name of the resource object where the event was raised in the standard message. The default is unselected.
Include AppManager event ID?	Select **Yes** to include the AppManager event ID in the standard message, possible only in cases when the Action is carried out by the management server. The default is unselected.

Include event detail message?	Select **Yes** to include the event detail message. The default is unselected.
	NOTE: In Microsoft Outlook 2003 SP2 environments, the detail message information may be unformatted and presented in one string of text, such as in the following example:
	`Detail Message:  Memory Utilization:  Top 10 Consuming Processes`
	`==========`
	`Process Name:  Rtvscan Process ID (PID): 1684 Utilization (KB): 51,528.00 Process Name:  NetIQmc Process ID (PID): 3424 Utilization (KB): 23,956.00 Process Name:  svchost#4 Process ID (PID): 832 Utilization (KB): 17,784.00`

Custom Message Options	
Custom message subject	Provide the text you want to use for the custom message subject line.

Parameter	How to Set It
Custom message body	Provide the text you want to include in your custom message. You can use the keywords listed below to indicate the information you want to include in the body of your custom message. Add a space before and after keywords to ensure that the keywords display properly. • `$ShortMsg$` (short event message) • `$DetailMsg$` (detailed event message) • `$Time$` (date and time of the event) • `$JobID$` (ID of the job that raised the event) • `$MachineName$` (name of the computer where the event was raised) • `$Severity$` (severity of the event) • `$KSName$` (name of the Knowledge Script that raised the event) • `$ObjectName$` (name of the AppManager resource object where the event was raised) • `$EventID$` (event ID) • `$tab$` inserts four whitespace characters in the message body • `$lf$` inserts a line feed in the message body • `$crlf$` inserts a carriage-return line feed in the message body • `$cr$` inserts a carriage-return in the message body For `$ShortMsg$` and `$DetailMsg$` you can use number and wildcard options to indicate specific portions of the text string to include. For example: • `$DetailMsg$[5]` includes the fifth word of the detailed event message • `$ShortMsg$[1-5]` includes the first through fifth words of the short message event • `$DetailMsg$[*5]` includes the first through fifth words of the detailed event message • `$ShortMsg$[5*]` includes the fifth through last words of the short event message This script treats the following character values as separators between words: carriage return, line feed, carriage return/line feed combination, form feed, horizontal tab, and space. Everything between those character values in a custom message is considered a word. If you do not enter a keyword, AppManager returns the entire string. The following are examples of the types of messages you can construct using keywords: • Event from `$MachineName$`: The `$ShortMsg$[1-3]` has failed. The last command was `$DetailMsg$[4*]`. • A severity `$Severity$` event has occurred. Call the owner of `$MachineName$` immediately.

2.31 SMTPMailRpt

This Knowledge Script supports the report-related (ReportAM) Knowledge Scripts, which can be application-specific reports or generic reports.

Use this Knowledge Script to email the first page of a report to a list of recipients.

The first page of the report contains a list of parameter values and hyperlinks to subsequent pages of the report. The hyperlinks refer to files on the computer where the report is located, so the email is lightweight (approximately 6-10 KB).

For this Action to succeed, generate reports on the same computer where the Report agent is installed, and use the AMAdmin_SetReportPaths Knowledge Script to display the location of each report as a hyperlink. Run AMAdmin_SetReportPaths on the AppManager Repositories object under the Report agent.

If the Admin_SetReportPaths Knowledge Script has not been used to display report locations as hyperlinks, the hyperlinks in the email message will not work.

If there is no data in the report, the email message will not be sent.

The **Location** for this Action must be defined as **MC** (referring to the managed computer where the Report agent is installed), and the Report agent computer must have Internet connectivity to be able to send mail.

NOTE: SMTPMailRpt will not send reports to Lotus Notes client because of a limitation with Lotus Notes in displaying the PNG images. For more information, see http://www-1.ibm.com/support/docview.wss?rs=0&q1=1090737&uid=swg21090737&loc=en_US&cs=utf-8&lang=

2.31.1 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Event Notification	
Raise event if SMTP server is not accessible?	Select **Yes** to raise an event when the SMTP server is not accessible. The default is Yes.
Event severity - SMTP server not accessible	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the SMTP server is not accessible. The default is 35 (magenta event indicator).
Event severity – Action failure	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the SMTPMailRpt job fails. The default is 5 (red event indicator).
Severity Configuration	
Minimum event severity for Action	Set the minimum severity level, from 1 to 40, for an event that triggers this action. The default is 1.
Maximum event severity for Action	Set the maximum severity level, from 1 to 40, for an event that triggers this action. The default is 40.
Action	

Parameter	How to Set It
List of recipient email addresses	Provide the email address of each individual who should receive the report, using the format <recipient>@<domain> (for example, SLAAdmin@netiq.com). Use commas (,) to separate multiple recipient addresses. **NOTE:** The following characters are invalid in this parameter: / \ [ ] : | = , * ? < >
Sender's email address	Provide the email address of the person sending the message. **Notes** • In Microsoft Exchange Server 2007 environments, specify the sender name in SMTP format: <name>@<domain>. • The following characters are invalid in this parameter: / \ [ ] : | = , * ? < >
SMTP server name	Specify the name of the SMTP mail server used to send mail from the Report agent computer.
SMTP server port	Set the port number for your SMTP server. The default is 25.
Message format	Select the format you want to use for the message sent by this script: • **Standard** format generates a message based upon the selections you make from the *Standard message options* parameters. • **Custom** format generates a message based upon the subject and message body you supply in the *Custom message options* parameters. The default is Standard.
Standard Message Options	
Include date/timestamp?	Select **Yes** to include the date/timestamp in the standard message. The default is unselected.
Include JobID?	Select **Yes** to include the job ID in the standard message. The default is unselected.
Include agent computer name?	Select **Yes** to include the name of the agent computer in the standard message (the computer hosting the agent that initiated the action). The default is Yes.
Include event severity?	Select **Yes** to include the severity of the event in the standard message. The default is Yes.
Include Knowledge Script name?	Select **Yes** to include the Knowledge Script name in the standard message (the Knowledge Script that initiated the action). The default is unselected.
Include AppManager object name?	Select **Yes** to include the AppManager resource object name in the standard message (the AppManager resource object where the event was raised). The default is unselected.
Include event detail message?	Select **Yes** to include the event detail message. The default is unselected.
Custom Message Options	
Custom message subject	Provide a subject line for the email message. This parameter is optional. If this parameter is not set, the report title is used for the subject line.

Parameter	How to Set It
Custom message body	Provide the text you want to include in your custom message. You can use the keywords listed below to indicate the information you want to include in the body of your custom message. Add a space before and after keywords to ensure that the keywords display properly. • `$ShortMsg$` (short event message) • `$DetailMsg$` (detailed event message) • `$Time$` (date and time of the event) • `$JobID$` (ID of the job that raised the event) • `$MachineName$` (name of the computer where the event was raised) • `$Severity$` (severity of the event) • `$KSName$` (name of the Knowledge Script that raised the event) • `$ObjectName$` (name of the AppManager resource object where the event was raised) • `$EventID$` (event ID) For `$ShortMsg$` and `$DetailMsg$` you can use number and wildcard options to indicate specific portions of the text string to include. For example: • `$DetailMsg$[5]` includes the fifth word of the detailed event message • `$ShortMsg$[1-5]` includes the first through fifth words of the short message event • `$DetailMsg$[*5]` includes the first through fifth words of the detailed event message • `$ShortMsg$[5*]` includes the fifth through last words of the short event message If you do not enter a word specifier, AppManager returns the entire string. The following are examples of the types of messages you can construct using these keywords: The following are examples of the types of messages you can construct using these keywords: • Event from `$MachineName$`: The `$ShortMsg$[1-3]` has failed. The last command was `$DetailMsg$[4*]`. • A severity `$Severity$` event has occurred! Call the owner of `$MachineName$` immediately!

2.32 SNMPTrap

Use this Knowledge Script to send an SNMP trap message with AppManager event information to a specified list of computers. Each computer you specify must be able to receive SNMP trap messages on UDP port 162.

If you do not specify a value for any of the parameters, this Knowledge Script uses the corresponding value found in the registry under: `HKEY_LOCAL_MACHINE\Software\NetIQ\AppManager\4.0\NetIQmc\SNMPTRAP\Config`.

For example, if you do not specify an object identifier in the OID field, the Knowledge Script checks the registry for the OID key entry: `OID: REG_SZ: 1.3.6.1.4.1.1691.1`.

By default, the event information includes the computer name of the managed client and the event severity. You can select additional information to include by enabling the appropriate parameters.

You can also specify a custom message to forward.

This script raises an event if you select the custom message format but neglect to enter any text for the custom message body. Under these circumstances, the script continues to execute and uses the standard message format.

2.32.1 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Event Notification	
Event severity – Action warning	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the SNMPTrap job returns a warning. The default is 35 (magenta event indicator).
Event severity – Action failure	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the SNMPTrap job fails. The default is 5 (red event indicator).
Severity Configuration	
Minimum event severity for Action	Set the minimum severity level, from 1 to 40, for an event that triggers this Action. The default is 1.
Maximum event severity for Action	Set the maximum severity level, from 1 to 40, for an event that triggers this Action. The default is 40.
Action	
List of computers to receive SNMP message (comma-separated)	Provide the name of the computer to receive the recipient of the SNMP trap message. The recipient computer must be able to receive SNMP traps on UDP Port 162. To specify multiple recipients, separate computer names with commas. For example, `Nancy01,10.41.40.16,finance03.us.netiq.corp`.
Community string	Provide a valid SNMP community string. Leave this parameter blank to use the SNMP community string entered in AppManager Security Manager. The default is `public`.
Destination port	Provide the number of the port where you want the trap sent. The default is 162.

Parameter	How to Set It
Object identifier	Provide an object identifier in OID notation (for example, `1.2.3.456.78`). The default is the NetIQ enterprise OID, `1.3.6.1.4.1.1691`.
Specific trap number	Specify a trap number. The trap number can be specific to your application. The default is 1.
Message format	Select the format you want to use for the message sent by this script: • **Standard** format generates a message based upon the selections you make from the *Standard message options* parameters. • **Custom** format generates a message based upon the subject and message body you supply in the *Custom message options* parameters. The default is Standard.
Standard Message Options	
Include JobID?	Select **Yes** to include the job ID in the standard message. The default is unselected.
Include agent computer name?	Select **Yes** to include the name of the agent computer in the standard message (the computer hosting the agent that initiated the Action). The default is Yes.
Include event severity?	Select **Yes** to include the severity of the event in the standard message. The default is Yes.
Include Knowledge Script name?	Select **Yes** to include the Knowledge Script name in the standard message (the Knowledge Script that initiated the Action). The default is unselected.
Include AppManager object name?	Select **Yes** to include the AppManager resource object name in the standard message (the AppManager resource object where the event was raised). The default is unselected.
Include AppManager event ID (only on MS Action)?	Select **Yes** to include the AppManager event ID in the standard message (possible only in cases when the Action is carried out by the management server). The default is unselected.
Include event detail message?	Select **Yes** to include the event detail message. The default is unselected.
Custom Message Options	

Parameter	How to Set It
Custom message (can include substitutions)	Provide the text to include in your custom message. Enter the custom message text without quotes. Use the following keywords to indicate the information to include in the message: • `$ShortMsg$` (the short event message) • `$DetailMsg$` (the detailed event message) • `$Time$` (the date and time of the event) • `$JobID$` (the ID of the job that raised the event) • `$MachineName$` (the name of the computer where the event was raised) • `$Severity$` (the severity of the event) • `$KSName$` (the name of the Knowledge Script that raised the event) • `$ObjectName$` (the name of the AppManager resource object where the event was raised) • `$EventID$` (the event ID) For `$ShortMsg$` and `$DetailMsg$` you can use number and wildcard options to indicate specific portions of the text string to include. For example: • `$DetailMsg$[5]` includes the fifth word of the detailed event message • `$ShortMsg$[1-5]` includes the first through fifth words of the short message event • `$DetailMsg$[*5]` includes the first through fifth words of the detailed event message • `$ShortMsg$[5*]` includes the fifth through last words of the short event message If you do not enter a word specifier, AppManager returns the entire string. The following are examples of the types of messages you can construct using these keywords: • Event from `$MachineName$`: The `$ShortMsg$[1-3]` has failed. The last command was `$DetailMsg$[4*]`. • A severity `$Severity$` event has occurred! Call the owner of `$MachineName$` immediately!

2.33 StartServices

Use this Knowledge Script to start Windows services in response to an event.

You can specify a number of seconds to wait after initiating the `service start` command to check the status of the service and make that it was successfully started.

NOTE: If the service you specify has dependent services, enter the names of dependent services after the name of the primary service. For example, SQLServerAgent is a dependent service of MSSQLServer. To start MSSQLServer and its dependent service, specify `MSSQLServer,SQLServerAgent` for the *Service name(s)* parameter. In cases with multiple dependent services, specify the least dependent service first and the most dependent service last.

2.33.1 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Event Notification	
Raise event if service is successfully started?	Select **Yes** to raise an event when the services you specify are successfully started. The default is unselected.
Event severity – Service started	Set the event severity level, from 1 to 40, to indicate the importance of an event in which a service is successfully started. The default is 25 (blue event indicator).
Event severity – Action Failure	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the StartServices job fails. The default is 10 (red event indicator). This Knowledge Script always raises an event when it is unable to start a service.
Severity Configuration	
Minimum event severity for Action	Set the minimum severity level, from 1 to 40, for an event that triggers this Action. The default is 1.
Maximum event severity for Action	Set the maximum severity level, from 1 to 40, for an event that triggers this Action. The default is 40.
Action	
Service name(s) (comma-separated, no spaces)	Provide a comma-separated list of the services you want to start. You can use the *service name* or *display name* listed in the Properties dialog box for the service. **NOTE:** If the service you specify has dependent services, enter the names of dependent services after the primary service. For example, `SQLServerAgent` is a dependent service of `MSSQLServer`. If you want to start `MSSQLServer` and all of its dependent services, specify `MSSQLServer,SQLServerAgent`.
Service start timeout	Set the number of seconds to attempt to start the specified services before timing out. The default is 10.

2.34 StopServices

Use this Knowledge Script to stop Windows services in response to an event.

NOTE: If the service you specify has dependent services, you must list the dependent services before the primary service. For example, SQLServerAgent is a dependent service of MSSQLServer. To stop MSSQLServer and its dependent service, specify `SQLServerAgent,MSSQLServer` for the *Service name(s)* parameter. In cases with multiple dependent services, specify the most dependent service first and the least dependent service last.

2.34.1 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Event Notification	
Raise event if service is successfully stopped?	Select **Yes** to raise an event if the services you specify are successfully stopped. The default is unselected.
Event severity – Service stopped successfully	Set the event severity level, from 1 to 40, to indicate the importance of an event in which services are successfully stopped. The default is 25 (blue event indicator). This Knowledge Script always raises an event when it is unable to stop a service.
Raise event if service is already stopped?	Select **Yes** to raise an event if the services you specify are already stopped. The default is unselected.
Event severity – Service already stopped	Set the event severity level, from 1 to 40, to indicate the importance of an event in which specified services are already stopped. The default is 25 (blue event indicator).
Raise event if service is missing?	Select **Yes** to raise an event if the services you specify are missing. The default is unselected.
Event severity – Service missing	Set the event severity level, from 1 to 40, to indicate the importance of an event in which specified services cannot be found. The default is 25 (blue event indicator).
Event severity – Action failure	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the StopServices job fails. The default is 10 (red event indicator).
Severity Configuration	
Minimum event severity for Action	Set the minimum severity level, from 1 to 40, for an event that triggers this Action. The default is 1.
Maximum event severity for Action	Set the maximum severity level, from 1 to 40, for an event that triggers this Action. The default is 40.
Action	

Parameter	How to Set It
Service name(s) (comma-separated, no spaces)	Provide a comma-separated list of the services you want to stop. You can use the *service name* or *display name* listed in the Properties dialog box for the service. **NOTE:** If the service you specify has dependent services, enter the dependent services before the primary service. For example, `SQLServerAgent` is a dependent service of `MSSQLServer`. If you want to stop `MSSQLServer` and all of its dependent services, specify `SQLServerAgent,MSSQLServer`.
Service stop timeout	Set the number of seconds to attempt to stop the specified services before timing out. The default is 30.

2.35 Traceroute

Use this Knowledge Script to collect exception traceroute data between a specified source and target location in response to an event in another Knowledge Script.

When you enable this script to run automatically in association with another Knowledge Script job, you must specify the source and target locations of the traceroute as parameters. The source location *must* have the ResponseTime for Networks managed object installed and discovered.

When you associate this Action with a monitoring Knowledge Script, you must set the **Location** to **MC** to run the Action on the managed client. Otherwise, this Action creates an error event and will not collect traceroute data when it is invoked.

NOTE: Although any managed client can be selected as the Location, the ResponseTime for Networks managed object must be installed on the managed client.

On the Actions tab, set the Action **Type** value to **Repeat Event - 1** to run a new traceroute each time an event occurs. The **Type** value is dependent on the settings for event collapsing and on the schedule of the associated Knowledge Script. If the Knowledge Script runs and generates events more often than the event collapsing interval (default is 20 minutes), the traceroute Action will not occur at every event. A new child event must be generated for the Action to be executed.

2.35.1 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Traceroute source location	The source is where the traceroute is run from. Select a ResponseTime for Networks node. The field may not be left blank. Specify only one source.
Traceroute target location	The target is where the traceroute will be run to. Select a ResponseTime for Networks node, some other AppManager node, an IP address, or a URL. The field may not be left blank. Specify only one target. The script will validate the source and target locations are not the same, and will generate an error if they are identical.
Maximum number of hops	Set the maximum number of hops, from 1 to 30, allowed in the traceroute. The default is 30.
Event when traceroute fails?	Set to y to raise events if the Traceroute job fails. The default is y.
Event severity – Traceroute failure	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the Traceroute job fails. The default is 20.

2.35.2 Example of How this Script Is Used

Before you launch a Knowledge Script (other than one of the Networks-RT scripts), double-click it to see its Properties dialog box. Click the **Actions** tab. Click **New** and select **Action_Traceroute** from the list. Then click **Properties** to specify the source location and target location for the traceroute. If an event is generated by the Knowledge Script, the Action_Traceroute Knowledge Script is launched automatically. It

collects traceroute data between the source and target you selected and stores the traceroute data in the AppManager repository.

The traceroute data is associated with the event that triggered the traceroute. Run the Report_TracerouteException Knowledge Script to generate a report that compares the traceroute data collected for this event with the historical traceroute data for the associated source and target locations.

2.36 TracerouteNetworks-RT

Use this Knowledge Script to collect exception traceroute data between a specified source and target location in response to an event in a separate Networks-RT Knowledge Script.

You do not have to specify source or target information when associating the Action script with the Knowledge Script. This script automatically determines the source and target locations for the traceroute, based on the event details from the Knowledge Script.

When you associate this Action with a monitoring Knowledge Script, you must set the **Location** to **MC** to run the Action on the managed client. Otherwise, this Action creates an error event and will not collect traceroute data when invoked.

NOTE: Although any managed client can be selected as the Location, the ResponseTime for Networks managed object must be installed on the managed client.

On the Actions tab, set the Action **Type** value to **Repeat Event - 1** to run a new traceroute each time an event occurs. The **Type** value is dependent on the settings for event collapsing and on the schedule of the associated Knowledge Script. If the Knowledge Script runs and generates events more often than the event collapsing interval (default is 20 minutes), the traceroute Action will not occur at every event. A new child event must be generated for the Action to be executed.

2.36.1 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Maximum number of hops	Set the maximum number of hops, from 1 to 30, allowed in the traceroute. The default is 30.
Event when traceroute fails?	Set to y to raise an event if the TracerouteNetworks-RT job fails. The default is y.
Event severity for traceroute failure	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the TracerouteNetworks-RT job fails. The default is 20.

2.36.2 Example of How this Script Is Used

Before you launch a Networks-RT Knowledge Script, double-click it and click the **Actions** tab on the Properties dialog box. Click **New**, and select **Action_TracerouteNetworks-RT** from the list. If an event is generated by the Knowledge Script, the Action_TracerouteNetworks-RT Knowledge Script is launched automatically. It collects traceroute data between the source and target locations associated with the event, and stores the traceroute data in the AppManager database.

The traceroute data is associated with the event that triggered the traceroute. Run the Report_TracerouteException Knowledge Script to generate a report that compares the traceroute data collected for this event with the historical traceroute data for the given pair of endpoints.

2.37 UpdateEventStatus

Use this Action Knowledge Script to acknowledge or close AppManager events from one or more specified computers. If you do not specify any computer, the computer that submitted the event is used. This script raises an event if an action fails.

2.37.1 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Event Notification	
Severity for Action failure	Set the severity level, from 1 to 40, to indicate the importance of the event when the UpdateEventStatus job fails. The default is 5 (red event indicator).
Severity Configuration	
Minimum event severity for Action	Set the minimum severity level, from 1 to 40, for an event that triggers this Action. The default is 1.
Maximum event severity for Action	Set the maximum severity level, from 1 to 40, for an event that triggers this Action. The default is 40.
Action	
SQL Server login	Specify the database user account used to run this Knowledge Script, for example, `sa`. You can run this Knowledge Script using other user accounts that have been set up in the SQL Server of the managed client and have been given permission to run SQL Knowledge Scripts through the AppManager Security Manager.
Repository Server	Provide the name of the server that hosts the AppManager repository.
Repository Database Name	Provide the name of the AppManager repository. The default is QDB.
Update event status to...	Select the update event status as closed or acknowledged. By default, the update event status is Acknowledged.
Filter Options	
Filter by computers?	Select **Yes** to filter events by computers. The default is Yes.
Filter by the computer that raised the event?	Select **Yes** to include the computer that raised the event. The default is Yes.
Filter by these computers (comma-separated list)	Select the computers or provide a comma-separated list of computer names by which you want to filter events. For example: `QELAB,PORT1,Chris`
Filter by these Knowledge Scripts (comma-separated list)	Provide a comma-separated list of Knowledge Scripts by which you want to filter events. For example, `Action_IISContinueSite,Action_Messenger,Action_Diagnose`
Filter by event severity	Specify the severity level by which you want to filter events. By default, the event severity is 1 to 40.
Filter by event message	Specify the message by which you want to filter events. The event message indicates whether or not the action was successful, and provides an explanation if the action fails.

Parameter	How to Set It
Filter by event age	Specify the age of the event. The default is 0 minutes.
Include only events that are...	Indicate whether to include newer or older events based on the age of the event. The default is Older.

2.38 UXCommand

Use this Knowledge Script to run a non-interactive UNIX command in response to an event. For example, you can use this Knowledge Script to run a batch command for appending a log file or stopping a process.

You can include arguments in the command-line string, but you need to escape any double quote (") or special characters by typing a preceding backslash (\). Special characters for Perl-based scripts include the dollar sign ($), percentage (%), and at symbol (@). In addition, avoid using the ampersand (&), the dollar sign ($), or backquotes (‘) in the command string.

2.38.1 Setting Parameter Values

Set the following parameter as needed:

Parameter	How to Set It
Non-interactive UNIX command	Specify the command to run. Do not enter a command that requires user input. If your command line includes double quotes or any other special characters, use a backslash to escape the characters. For example: `grep -l \"Abnormal shutdown\" applog* > /tmp/fail`. The command you enter should include all necessary arguments and handle any input and output redirection or file management required.

2.38.2 Example of How this Script Is Used

Use this Action is to create a script file that contains a series of commands to diagnose or correct problems on a server you are monitoring and have this Action launch your script file when an event is detected.

To run this Action on the managed UNIX computer, select **MC** (Managed Client) as the Location on the **Action** tab of the Properties dialog box. Also verify that the NetIQ UNIX agent account has permission to execute the command you want to run on the computer where you want the Action executed.

2.39 WriteMsgToFile

Use this Knowledge Script to write AppManager event information to a file. This file gets written to the computer that is running the action. The designation of that computer is controlled by the Action dialog when the monitoring job is created, and the options are `MC` (agent), `MS` (management server), or `proxy`, where proxy in turn prompts the user to designate any agent computer that is known to AppManager.

By default, the event information includes the agent computer name and the event severity level. You can select additional information to include by enabling the appropriate parameters.

You can also construct a custom message.

An event is raised when you select the custom message format but neglect to enter any text for the custom message body. Under these circumstances, the script continues to execute and uses the standard message format.

2.39.1 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Event Notification	
Event severity – Action warning	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the WriteMsgToFile job returns a warning. The default is 35 (magenta event indicator).
Event severity – Action failure	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the WriteMsgToFile job fails. The default is 5 (red event indicator).
Severity Configuration	
Minimum event severity for Action	Set the minimum severity level, from 1 to 40, for an event that triggers this Action. The default is 1.
Maximum event severity for Action	Set the maximum severity level, from 1 to 40, for an event that triggers this Action. The default is 40.
Action	
Full path to file	Provide the complete path to the file where you want to store event information or click Browse [...] to find the file. The default is `c:\temp\NetiQACT_Dump.txt`.
Append event information?	Select **Yes** to append event information to the specified file. If you do not select this check box, the log file is overwritten each time the Action runs. The default is Yes.
Create folder if it does not exist?	Select **Yes** to create folders specified in the file path if they do not exist. The default is Yes.
Message format	Select the format you want to use for the message sent by this script: • **Standard** format generates a message based upon the selections you make from the *Standard Message Options* parameters. • **Custom** format generates a message based upon the subject and message body you supply in the *Custom Message Options* parameters. The default is Standard.

Parameter	How to Set It
Standard Message Options	
Include date/timestamp?	Select **Yes** to include the date/timestamp in the standard message. The default is unselected.
Include JobID?	Select **Yes** to include the job ID in the standard message. The default is unselected.
Include agent computer name?	Select **Yes** to include the name of the agent computer in the standard message (the computer hosting the agent that initiated the Action). The default is Yes.
Include event severity?	Select **Yes** to include the severity of the event in the standard message. The default is Yes.
Include Knowledge Script name?	Select **Yes** to include the Knowledge Script name in the standard message (the Knowledge Script that initiated the Action). The default is unselected.
Include AppManager object name?	Select **Yes** to include the AppManager resource object name in the standard message (the AppManager resource object where the event was raised). The default is unselected.
Include AppManager event ID (only on MS Action)?	Select **Yes** to include the AppManager event ID in the standard message (possible only in cases when the Action is carried out by the management server). The default is unselected. **NOTE:** This Knowledge Script also displays the event ID on the proxy computer.
Include event detail message?	Select **Yes** to include the event detail message. The default is unselected.
Custom Message Options	

Parameter	How to Set It
Custom text (can include substitutions)	Provide the text you want to include in your custom message. You can use the keywords listed below to indicate the information you want to include in the body of your custom message. Add a space before and after keywords to ensure that the keywords display properly. • `$ShortMsg$` (short event message) • `$DetailMsg$` (detailed event message) • `$Time$` (date and time of the event) • `$JobID$` (ID of the job that raised the event) • `$MachineName$` (name of the computer where the event was raised) • `$Severity$` (severity of the event) • `$KSName$` (name of the Knowledge Script that raised the event) • `$ObjectName$` (name of the AppManager resource object where the event was raised) • `$EventID$` (event ID) • `$tab$` inserts four whitespace characters in the message body • `$lf$` inserts a line feed in the message body • `$crlf$` inserts a carriage-return line feed in the message body • `$cr$` inserts a carriage-return in the message body For `$ShortMsg$` and `$DetailMsg$` you can use number and wildcard options to indicate specific portions of the text string to include. For example: • `$DetailMsg$[5]` includes the fifth word of the detailed event message • `$ShortMsg$[1-5]` includes the first through fifth words of the short message event • `$DetailMsg$[*5]` includes the first through fifth words of the detailed event message • `$ShortMsg$[5*]` includes the fifth through last words of the short event message If you do not enter a word specifier, AppManager returns the entire string. The following are examples of the types of messages you can construct using these keywords: • Event from `$MachineName$`: The `$ShortMsg$[1-3]` has failed. The last command was `$DetailMsg$[4*]`. • A severity `$Severity$` event has occurred! Call the owner of `$MachineName$` immediately!

3 AD Knowledge Scripts

To help you set up AppManager for Microsoft Active Directory monitoring in accordance with NetIQ recommended best practices guidelines, five Knowledge Script Groups are provided. For more information, see "AD Knowledge Script Groups" on page 189.

From the Knowledge Script view of Control Center, you can access more information about any NetIQ-supported Knowledge Script by selecting it and clicking **Help**. Or in the Operator Console, click any Knowledge Script in the Knowledge Script pane and press **F1**.

Knowledge Script	What It Does
Authentications	Monitors the number of AD Kerberos and NT LAN Manager (NTLM) authentications per second.
BridgeheadChange	Monitors changes to the bridgehead roles in an Active Directory.
CacheHitRate	Monitors the Active Directory cache hit rate for name resolution.
ClientSessions	Monitors the total number of Active Directory client sessions: LDAP (Lightweight Directory Access Protocol), AB (address book), and XDS (external and foreign directory) connections.
ConnectivityObject	Verifies connectivity between the local target computer and the Active Directory object (domain, computer or user) you specify.
DatabaseSize	Monitors the Active Directory database logical disk space usage.
DCAdvertised	Checks whether the Active Directory domain controller is being advertised properly to Active Directory clients.
DCHealthMonitor	Monitors CPU and memory usage, disk space availability, and LSASS (the Windows Local Security Authority Server process) CPU and memory usage for an Active Directory domain controller.
DCInSiteConnectivity	Checks connectivity to domain controllers in the local site container.
DomainConnectivity	Monitors the connectivity between a domain controller and selected domains.
EnumerateSites	Monitors changes to sites in an Active Directory forest.
EventLog	Monitors the Windows Event Log for Active Directory entries that match your filtering criteria.
EventLog (NetLogon)	Monitors the Windows Event Log for Active Directory entries associated with the NetLogon service that match your filtering criteria.
EventLog (W32Time)	Monitors the Windows Event Log for Active Directory entries associated with the Windows Time service that match your filtering criteria.
FSMOChange	Monitors changes to Flexible Single Master Operations (FSMO) roles in an Active Directory forest.

Knowledge Script	What It Does
FSMOHealth	Monitors access to the domain controllers that have been given any Flexible Single Master Operations (FSMO) role.
FSMOPlacement	Monitors the placement of a Flexible Single Master Operations (FSMO) role in accordance with Microsoft Best Practices.
GlobalCatalogChange	Monitors changes to the list of global catalog servers defined in the forest.
GlobalCatalogHealth	Monitors access to the global catalog servers defined in the forest.
InboundReplStat	Monitors the Inbound replication rate (inbound replication requests per second) in the Active Directory, and the percentage of applied and filtered requests.
InterReplTraffic	Monitors replication traffic from the DRA (Directory Replication Agent) between Active Directory sites (intersite traffic).
IntraReplTraffic	Monitors replication traffic from the DRA (Directory Replication Agent) within an Active Directory site (intrasite traffic).
KCCConnections	Monitors the number of KCC (Knowledge Consistency Checker) connections to and from a server within a site.
KCCDisabled	Checks whether the KCC is enabled or disabled for a site or server. You can set this script to automatically reenable the KCC if it is disabled.
KDCRequests	Monitors the number of Active Directory requests serviced by KDC per second.
NumberOfComputers	Monitors the number of computers in a domain or organizational unit.
NumberOfDCs	Monitors changes in the number of domain controllers in a domain, site, or forest.
NumberOfGCs	Monitors changes to the number of global catalog servers in a domain, site, or forest.
NumberOfGroups	Monitors the number of groups in a domain or organizational unit.
NumberOfObjects	Monitors the number of objects in a domain or organizational unit.
NumberOfPrintQueues	Monitors the number of printer queues in a domain or organizational unit.
NumberOfUsers	Monitors the number of users in a domain or organizational unit.
NumberOfUsersLocked	Monitors the number of locked user accounts in a domain or organizational unit.
OutboundReplStat	Monitors the outbound replication rate (outbound replication requests per second) in the Active Directory, and the percentage of Applied and Filtered requests.
PropertyWatch	Monitors changes to any property of any Active Directory object.
ReadStat	Monitors the number of Active Directory read operations per second.
ReplEventLog	Scans the System log for replication errors matching your criteria.
ReplicationCheckByUSN	Monitors replication of the Active Directory using USNs (Update Sequence Numbers).
ReplicationLatency	Injects changes to Active Directory partitions and monitors replication latency.
ReplQueueLen	Monitors the queue length for unprocessed Active Directory replication synchronization requests.
ReplSysVol	Monitors SysVol folder replication.

Knowledge Script	What It Does
ResponseTime	Monitors the connection and read response times from the target computer to a specified Active Directory domain controller.
SearchStat	Monitors the number of Active Directory search operations per second.
ServerHealth	Monitors the health of an Active Directory domain controller.
SyncRequest	Monitors Active Directory synchronization requests and the percentage of replication synchronization requests that fail.
WriteStat	Monitors the number of Active Directory write operations per second.
AD Knowledge Script Groups	
AD	Performs essential monitoring for Active Directory domain controllers using job delegation.
AD (all DCs)	Performs essential monitoring for all domain controllers.
AD (one DC per domain)	Performs essential monitoring for a single domain controller in each domain.
AD (one DC per forest)	Performs essential monitoring for a single domain controller in a forest.
AD (one DC per site)	Performs essential monitoring for a single domain controller per site.

3.1 AD Knowledge Script Job Delegation

Some Knowledge Scripts in the AD category include an optional "job delegation" feature that automatically determines where a monitoring job should run.

Use job delegation to select the server role that should run the job. If the role-holder changes, an event is raised, and the job is delegated to the server that now holds the selected role. Forest-wide monitoring can be delegated to the Schema Master or Domain Master. Domain-wide monitoring can be delegated to the Relative ID (RID) master, the Primary Domain Controller (PDC), or the infrastructure master (IM). Site-wide monitoring can be delegated to the Inter-Site Topology Generator (ISTG).

For example, to run a Knowledge Script job on all servers in the forest that have the Domain Master role, enable job delegation and then deploy the script to all domain controllers (DCs) in the forest. The job will run only on the DC that is currently holding the Domain Master role. Anytime a DC relinquishes or assumes that role, an event informs you of the change. But the job continues to run according to its schedule, automatically delegating the monitoring tasks only to servers holding the Domain Master role. To achieve complete coverage, include all DCs in your forest when deploying the script.

Use the job delegation feature instead of selecting and re-selecting the DCs for a Knowledge Script job. Instead of re-deploying the script every time a server role changes, you can select a regular schedule and deploy the script once. The script then automatically runs only on the DCs holding a certain server role. You can also avoid creating special server groups to deploy scripts to, say, a DC from every domain. Instead, you can enable job delegation and run the script on all DCs in the forest. The job will run only on DCs holding the server role you selected — one per domain — not on every DC in the forest.

Included as part of the recommended Knowledge Script Groups (KSGs) in AppManager for Active Directory is a KSG named "AD" that uses the job delegation feature. For more information, see "AD" on page 190.

Job delegation works because the script itself determines if each server you run the script on is holding the role you selected for the *Delegate monitoring to the [Active Directory server role]* parameter. If a server is no longer holding that role, the script does the following:

- Raises an event notifying you of the change.
- Forces monitoring on that server to sleep for that schedule interval.

The DC that assumes the selected server role then performs the monitoring job.

The Knowledge Script job delegation feature also allows and event to be raised when a DC assumes the selected server role.

The following scripts offer job delegation:

- BridgeheadChange
- DCInSiteConnectivity
- DomainConnectivity
- EnumerateSites
- FSMOChange
- FSMOHealth
- FSMOPlacement
- GlobalCatalogChange
- GlobalCatalogHealth
- KCCDisabled
- NumberOfComputers
- NumberOfDCs
- NumberOfGCs
- NumberOfGroups
- NumberOfObjects
- NumberOfPrintQueues
- NumberOfUsers
- NumberOfUsersLocked

3.2 Authentications

Use this Knowledge Script to monitor the number of Kerberos and NTLM (Windows NT LAN Manager) authentications per second. This script raises an event if the number of Kerberos or NTLM authentications per second exceeds the threshold you set.

The default protocol for network authentication for computers with Windows 2000 and later is Kerberos, but because Windows 2000 also supports NTLM authentication, this script monitors both types of network authentication.

Windows requires users and workstations to receive authentication — to prove their identity — before servers allow them access to data. Authentication monitoring of domain controllers, which do much of the work associated with authentications, should be performed for several reasons:

- A rise in authentication load indicates authentication work has failed over to this domain controller from another domain controller.
- Sustained zero Kerberos authentication levels indicate Kerberos authentication has either failed over to another domain controller, or user authentications are failing entirely.
- A jump in authentication load is very common when a virus attack is underway.
- Any non-zero NTLM authentication load indicates legacy clients are connected.
- The ratio of Kerberos to NTLM traffic is a key indicator of how much of your client base has been upgraded to Windows 2000 or later.

This script gathers the following Windows performance counter values for use in data collection and threshold monitoring:

Performance Objects	Counters
NTDS	Kerberos Authentications
Security System-Wide Statistics	NTLM Authentications
NOTE: The Authentication Knowledge Script gathers values from the Security System-Wide Statistics performance object only when the Domain Controller where it runs is the Windows Server 2008 version or later.	

3.2.1 Resource Object

Active Directory domain controller

3.2.2 Default Schedule

The default interval for this script is **Every 30 minutes**.

The default interval is intended to minimize the amount of data collected. If your organization wants tight monitoring of security-related issues, you can decrease the interval to **Every 5 minutes**.

3.2.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Monitor authentication rate	
Event Notification	
Raise event if job fails	
Event severity when job fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the Authentications job fails. The default is 35.
Raise event if Kerberos authentication rate exceeds threshold?	Select Yes to raise an event if the Kerberos authentication rate exceeds the threshold you set. The default is Yes.
Threshold – Maximum rate of Kerberos authentications	Specify the maximum number of Kerberos authentications per second allowed during any interval before an event is raised. The default is 50 authentications per second.
Event severity when Kerberos authentication rate exceeds threshold	Set the severity level, from 1 to 40, to indicate the importance of an event in which the Kerberos authentication rate exceeds the threshold. The default is 20.
Raise event if NTLM authentication rate exceeds threshold?	Select Yes to raise an event if the NTLM authentication rate exceeds the threshold you set. The default is Yes.
Event severity when NTLM authentication rate exceeds threshold	Set the severity level, from 1 to 40, to indicate the importance of an event in which the NTLM authentication rate exceeds the threshold. The default is 20.
Threshold – Maximum rate of NTLM authentications	Specify the maximum number of NTLM authentications per second allowed during any interval before an event is raised. The default is 50 authentications per second.
Data Collection	
Collect data for Kerberos authentications?	Select Yes to collect data for charts and reports. If enabled, data collection returns the total number of Kerberos authentication requests since the first Knowledge Script interval (the cumulative number). The default is unselected.
Collect data for NTLM authentications?	Select Yes to collect data for charts and reports. If enabled, data collection returns the total number of NTLM authentication requests since the first Knowledge Script interval (the cumulative number). The default is unselected.

3.3 BridgeheadChange

Use this Knowledge Script to monitor changes to the bridgehead roles in an Active Directory forest. This script connects to the local Active Directory database of the target server and retrieves the list of bridgehead servers. In addition, this script raises an event if new bridgehead servers are added or existing bridgehead servers are run.

By default, Active Directory can move bridgehead servers as needed. Many large organizations manually designate which domain controllers will serve as bridgehead servers because there is significant load placed on bridgehead servers. If your organization has defined bridgeheads manually, use this script to report all bridgehead server changes. Otherwise, use this information to correlate with a condition of high CPU utilization. If they match, the bridgehead function is the cause of the high CPU load.

3.3.1 Resource Objects

Active Directory domain controller

3.3.2 Default Schedule

The default interval for this script is **Every 30 minutes**.

3.3.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Raise event if job fails	
Event severity when job fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the BridgeheadChange job fails. The default is 35.
Monitor bridgehead server changes	
Enable job delegation?	Select Yes to enable the delegation of the job to another server where appropriate. If enabled, the job runs on the computer that holds the server role (Domain Master or Schema Master) that you selected for the *Delegate forest-wide monitoring to the...* parameter. The default is unselected.For more information, see "AD Knowledge Script Job Delegation" on page 90.
Delegate forest-wide monitoring to the	Select the server role to delegate the job to: **Domain Master** or **Schema Master**. By default, the job is delegated to the Domain Master.
Raise event when DC assumes this role?	If you enabled job delegation, set to Yes to enable events if the DC assumes the server role you selected for the *Delegate forest-wide monitoring to the...* parameter. The event message indicates that the monitored computer has assumed the selected role. The default is Yes.
Event severity when DC assumes this role	Set the severity level, from 1 to 40, to indicate the importance of an event in which the DC assumes the role you selected for the *Delegate forest-wide monitoring to the...* parameter. The default is 30.

Parameter	How to Set It
Raise event when DC relinquishes this role?	If you enabled job delegation, set to Yes to enable events if the DC gives up the server role you selected for the *Delegate forest-wide monitoring to the...* parameter. The event message indicates that the monitored computer has relinquished the selected role. The default is Yes.
Event severity when DC relinquishes this role	Set the severity level, from 1 to 40, to indicate the importance of an event in which the DC relinquishes the role you selected for the *Delegate forest-wide monitoring to the...* parameter. The default is 30.
Event Notification	
Raise event if changes to bridgehead servers are detected?	Select Yes to raise an event if changes to the bridgehead servers are detected. The default is Yes.
Event severity when changes detected	Set the severity level, from 1 to 40, to indicate the importance of an event in which changes to the bridgehead servers are detected. The default is 25.
Data Collection	
Collect data for changes to bridgehead servers?	Select Yes to collect data for charts and reports. If enabled, data collection returns the number of bridgehead servers for the interval. The default is unselected.

3.4 CacheHitRate

Use this Knowledge Script to monitor the cache hit rate for the LSASS (Windows Local Security Authority Server) process. The cache hit rate is the percentage of time that a requested name is found in the Active Directory cache. This script raises an event if the cache hit rate falls below the threshold you set, which may indicate that you need to re-organize the Active Directory.

LSASS is the process responsible for core Active Directory functions performed using LDAP (Lightweight Directory Access Protocol). Ideally, all LDAP requests can be fulfilled out of RAM. However, when the cache hit rate falls below 95%, Active Directory performance falls off quickly. By 93%, Active Directory is typically unusable.

TIP: If the cache hit rate is low, consider adding physical RAM to the computer, or adding the /3GB switch to the `boot.ini` file.

This script gathers the following Windows performance counter values for use in data collection and threshold monitoring:

Performance Objects	Counter
NTDS	DS Name Cache hit rate
DirectoryServces	

3.4.1 Resource Object

Active Directory domain controller

3.4.2 Default Schedule

The default interval for this script is **Every 10 minutes**.

3.4.3 Setting Parameter Values

The default settings for the **Advanced** tab on the Properties dialog box are overridden for this script. Specifically, the *Collapse duplicates* option is disabled, and the *Raise event if event condition occurs* option is set to 3 times within 3 job iterations.

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Raise event if job fails	
Event severity when job fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the CacheHitRate job fails. The default is 35.
Monitor cache hit rate	

Parameter	How to Set It
Event Notification	
Raise event if cache hit rate falls below threshold?	Select Yes to raise an event if the cache hit rate falls below the threshold you set. The default is Yes.
Threshold – Minimum cache hit rate	Specify the minimum percentage of time that requested data should be found in the cache before an event is raised. The default is 93%.
Event severity when cache hit rate falls below threshold	Set the severity level, from 1 to 40, to indicate the importance of an event in which the cache hit rate falls below the threshold. The default is 20.
Data Collection	
Collect data for cache hit rate?	Select Yes to collect data for charts and reports. If enabled, data collection returns the name cache hit rate for the interval. By default, data is not collected.

3.5 ClientSessions

Use this Knowledge Script to monitor the number of Active Directory client sessions. Typically, there are three types of clients that need to access the Active Directory:

- Lightweight Directory Access Protocol (LDAP) clients
- Address book clients (AB clients)
- Exchange Directory Service clients (XDS clients)

The Active Directory system administrator configures a maximum number of threads to service each of these clients. With this script, you can set a threshold for maximum number of active clients sessions across all client session types. This script raises an event if the total number of client sessions exceeds the threshold you set.

A sudden surge in the number of clients may indicate that either another domain controller has gone offline, or that a change in the Active Directory subnet definitions has defined this DC as "closest."

If a surge is due to a change in Active Directory subnet definitions, then the DC being monitored may indeed be the closest server, in which case you should close the event. If this is not the intended closest DC, re-check your definitions to see why the expected DC is not in the correct site.

This script gathers the following Windows performance counter values for use in data collection and threshold monitoring:

Performance Objects	Counters
NTDS	LDAP Client Sessions
DirectoryServices	AB Client Sessions
	XDS Client Sessions

The total number of client sessions is calculated using the following formula:

```
Number of AB client sessions + Number of LDAP client sessions + Number of XDS client
```

3.5.1 Resource Objects

Active Directory domain controller

3.5.2 Default Schedule

The default interval for this script is **Every 30 minutes**.

3.5.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Raise event if job fails	
Event severity when job fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the ClientSessions job fails. The default is 35.
Monitor number of client sessions	
Event Notification	
Raise event if number of client sessions exceeds threshold?	Select Yes to raise an event if the number of client sessions exceeds the threshold you set. The default is Yes.
Threshold – Maximum number of client sessions	Specify the maximum number of active client sessions allowed during an interval before an event is raised. The default is -1 sessions. You must change the default setting to run this script. You should first collect data to establish a baseline, then specify a threshold appropriate to your environment.
Event severity when client sessions exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of client sessions exceeds the threshold you set. The default is 20.
Data Collection	
Collect data for number of client sessions?	Select Yes to collect data for charts and reports. If enabled, data collection returns the number of client sessions of each type for the interval. The default is unselected.

3.5.4 Example of Using this Knowledge Script

This script monitors all three types of client sessions and raises an event if the total number of client sessions exceeds the threshold. Although the event is based on the total number of client sessions, the script collects data for each type of client session separately. Because you can collect data on the number of sessions for each client type, you can use this script to analyze your client session usage and compare the usage patterns to your Active Directory configuration.

For example, assume you have configured the ATQ (Asynchronous Thread Queue) for LDAP to use a maximum of 100 threads. If you enable data collection, you can keep track of the number of LDAP client sessions detected at each interval. If you see a steady increase, you can check for stale or hung LDAP client sessions, which are sessions that have not timed out properly. If hung client sessions are not the cause of the problem and the computer is frequently near the maximum thread limit, you may need to increase the number of ATQ threads for servicing the LDAP clients.

You can also use the *Number of consecutive occurrences before raising an event* option, on the Advanced tab of the Properties dialog box, to determine whether client session activity is an ongoing problem or simply an unusual spike in activity.

3.6 ConnectivityObject

Use this Knowledge Script to verify connectivity between the target computer and the Active Directory objects (domains, computers, or users) you specify. This script raises an event if the computer cannot connect to the Active Directory object you specified.

3.6.1 Resource Objects

Any Windows computer

3.6.2 Default Schedule

The default interval for this script is **Every hour**.

3.6.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Raise event if job fails	
Event severity when job fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the ConnectivityObject job fails. The default is 35.
Monitor connectivity to an Active Directory object	
Active Directory object type	Select the Active Directory object to which you want to check connectivity: **domain**, **computer**, or **user**. The default is domain.
Object name (for user, type Domain/username)	Specify the name of the object to which you are checking connectivity. For example, if you specified the "domain" object, type the name of the domain to which you want to check connectivity. If you specified the "user" object, type the full user account name, including the domain. For example: `NC/wolfpack` The default entry is `rootDSE`.
Event Notification	
Raise event if connection fails?	Select Yes to raise an event if connection to the object fails. The default is Yes.
Event severity when connection fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which connection to the object fails. The default is 10.
Data Collection	
Collect data for connection status?	Select Yes to collect data for charts and reports. If enabled, data collection returns: • 100 – the connection was successful, or • 0 – the object is not accessible. The default is unselected.

3.7 DatabaseSize

Use this Knowledge Script to monitor logical disk space used by the Active Directory database file on a domain controller. This script monitors the percentage of disk space used and the database size (in MB). In addition, this script raises an event if the percentage of logical disk space used exceeds the threshold you set.

Lack of disk space prevents password changes and user adds and deletes, and causes many other problems. Correcting an out-of-disk space situation may involve adding hardware, moving the database to a different drive, or both. Both of these tasks involve extended outages.

WARNING: If multiple domain controllers suddenly alert to database growth problems, a replication storm may be occurring. Multiple DCs all running out of disk space concurrently can disable the entire company and be extremely costly and time-consuming to fix.

3.7.1 Resource Objects

Active Directory domain controller

3.7.2 Default Schedule

The default interval for this script is **Every 15 minutes**.

3.7.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Raise event if job fails	
Event severity when job fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the DatabaseSize job fails. The default is 35.
Monitor database size	
Event Notification	
Raise event if disk space usage exceeds threshold?	Select Yes to raise an event if disk space usage exceeds the threshold you set. The default is Yes.
Threshold – Maximum percentage of disk space used	Specify the maximum percentage of logical disk space that can be used by the Active Directory database file before an event is raised. The default is 80%.
Event severity when disk space usage exceeds threshold	Set the severity level, from 1 to 40, to indicate the importance of an event in which disk space usage exceeds the threshold. The default is 5.
Data Collection	

Parameter	How to Set It
Collect data for database disk space usage?	Select Yes to collect data for charts and reports. If enabled, data collection returns the percentage of disk space used by the database. The default is unselected.
Collect data for database size?	Select Yes to collect data for charts and reports. If enabled, data collection returns the size of the database (in MB). The default is unselected. **Tip** Consider enabling data collection if you are planning to migrate data to your Active Directory domain or to add large numbers of objects, such as users or computers.

3.8 DCAdvertised

Use this Knowledge Script to check whether an Active Directory domain controller (DC) is being advertised to Active Directory clients. This script performs a DC Locator lookup to verify that the DC is being advertised in DNS properly. In addition, this script raises an event if the DC is not being advertised.

This script monitors the `netlogon` process to ensure it is advertising the correct SRV (or service) records in DNS. These records are required by Active Directory so that clients can "find" Active Directory domain controllers. If a domain controller is not properly advertised, the domain controller will be under utilized because it cannot be found.

3.8.1 Resource Objects

Active Directory domain controller

3.8.2 Default Schedule

The default interval for this script is **Every 15 minutes**.

3.8.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
General Settings	
Raise event if job fails	
Event severity when job fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the DCAdvertised job fails. The default is 35.
Monitor directory service availability	
Event Notification	
Raise event if directory service is unavailable?	Select Yes to raise an event if the directory service is unavailable. The default is Yes.
Threshold – Maximum percentage of disk space used	Specify the maximum percentage of logical disk space that can be used by the Active Directory database file before . The default is 80%.
Event severity when directory service is unavailable	Set the event severity level, from 1 to 40, to indicate the importance of an event in which a directory service is unavailable. The default is 10.
Data Collection	
Collect data for directory service availability?	Select Yes to collect data for charts and reports. If enabled, data collection returns: • 100 – the domain controller is advertising, or • 0 – the domain controller is not advertising. The default is unselected.

3.9 DCHealthMonitor

Use this Knowledge Script to monitor CPU and memory usage, and disk space availability for an Active Directory domain controller. You can also use this script to monitor the CPU and memory usage for the `LSASS` process. This script raises an event if a monitored value exceeds the threshold you set.

LSASS, the Windows Local Security Authority Server process, handles Windows security mechanisms. It verifies the validity of user logons to your computer or server. Technically, the software generates the process that is responsible for authenticating users for the `Winlogon` service.

TIP: If you use this script, you should not need to perform additional operating system monitoring for CPU, memory, or disk space usage.

3.9.1 Resource Objects

Active Directory domain controller

3.9.2 Default Schedule

The default interval for this script is **Every 5 minutes**.

3.9.3 Setting Parameter Values

The default settings for the Advanced tab on the Properties dialog box are overridden for this script. Specifically, the *Collapse duplicates* option is disabled, and the *Raise event if event condition occurs* option is set to 3 times within 3 job iterations.

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Raise event if job fails	
Event severity when job fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the DCHealthMonitor job fails. The default is 35.
Monitor CPU, memory, and disk utilization?	
Event Notification	
Raise event if CPU utilization exceeds threshold?	Select Yes to raise an event if CPU usage exceeds the threshold you set. The default is Yes.
Threshold – Maximum CPU utilization	Specify the maximum percentage of CPU resources that can be used by the Active Directory domain controller before an event is raised. The default is 90%.
Event severity when CPU utilization exceeds threshold	Set the severity level, from 1 to 40, to indicate the importance of an event in which CPU usage exceeds the threshold. The default is 5.

Parameter	How to Set It
Raise event if memory utilization exceeds threshold?	Select Yes to raise an event if memory usage exceeds the threshold you set. The default is Yes.
Threshold – Maximum memory utilization	Specify the maximum percentage of memory resources that can be used by the Active Directory domain controller before an event is raised. The default is 90%
Event severity when memory utilization exceeds threshold	Set the severity level, from 1 to 40, to indicate the importance of an event in which memory usage exceeds the threshold. The default is 5.
Raise event if disk utilization exceeds threshold?	Select Yes to raise an event is disk usage exceeds the threshold you set. The default is Yes.
Threshold – Maximum disk utilization	Specify the maximum percentage of disk space that can be used by the Active Directory domain controller before an event is raised. The default is 90%.
Event severity when disk utilization exceeds threshold	Set the severity level, from 1 to 40, to indicate the importance of an event in which disk usage exceeds the threshold. The default is 5.
Data Collection	
Collect data for system CPU utilization?	Select Yes to collect data for charts and reports. If enabled, data collection returns the CPU usage of the server as a percentage of total CPU time. The default is unselected. **Tip** Enable this parameter for domain controller load trend analysis.
Collect data for system memory utilization?	Select Yes to collect data for charts and reports. If enabled, data collection returns the memory usage of the server (as a percentage of total system memory). The default is unselected. **Tip** Enable this parameter for domain controller load trend analysis.
Collect data for disk utilization?	Select Yes to collect data for charts and reports. If enabled, data collection returns the disk usage of the server (as a percentage of total disk space). The default is unselected. **Tip** Enable this parameter for domain controller load trend analysis.
Monitor memory and CPU for LSASS?	Select Yes to monitor CPU and memory usage of the LSASS process. The default is Yes.
Event Notification	
Raise event if LSASS CPU utilization exceeds threshold?	Select Yes to raise an event if LSASS CPU usage exceeds the threshold you set. The default is Yes.
Threshold – Maximum LSASS CPU usage	Specify the maximum percentage of CPU resources that can be used by LSASS before an event is raised. The default is 90%.
Event severity when LSASS CPU utilization exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which LSASS CPU usage exceeds the threshold. The default is 5.
Raise event if LSASS memory utilization exceeds threshold?	Select Yes to raise an event if LSASS memory usage exceeds the threshold you set. The default is Yes.
Threshold – Maximum LSASS memory usage	Specify the maximum amount of memory (in KB) that can be used by LSASS before an event is raised. The default is 1700000 KB (1.7 GB). **NOTE:** Set this parameter to 2700000 (2.7 GB) if the "`/3GB`" option is enabled in the `boot.ini` file.

Parameter	How to Set It
Event severity when LSASS memory utilization exceeds threshold	Set the severity level, from 1 to 40, to indicate the importance of an event in which LSASS memory usage exceeds the threshold. The default is 5.
Data Collection	
Collect data for LSASS CPU utilization?	Select Yes to collect data for charts and reports. If enabled, data collection returns the CPU usage of the LSASS process as a percentage of total CPU time. The default is unselected. **Tip** Enable this parameter for domain controller load trend analysis.
Collect data for LSASS memory utilization?	Select Yes to collect data for charts and reports. If enabled, data collection returns the memory usage of the LSASS process as a percentage of total LSASS memory. The default is unselected. **Tip** Enable this parameter for domain controller load trend analysis.

3.10 DCInSiteConnectivity

Use this Knowledge Script to check the connectivity to domain controllers in the local site. This script raises an event if connectivity to any Active Directory domain controller in the site fails.

3.10.1 Resource Objects

Active Directory site container on a domain controller

3.10.2 Default Schedule

The default interval for this script is **Every 10 minutes**.

3.10.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Raise event if job fails	
Event severity when job fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the DCInSiteConnectivity job fails. The default is 35.
Monitor connectivity to DCs in the same site	
Enable job delegation?	Select Yes to enable the delegation of the job to another server where appropriate. If enabled, runs the job on the selected computer that holds the Inter-Site Topology Generator (ISTG) server role. The default is unselected. For more information, see "AD Knowledge Script Job Delegation" on page 90.
Delegate site-wide monitoring to the	Indicates the server role to which the job should be delegated, the ISTG.
Raise event when DC assumes this role?	If you enabled job delegation, set to Yes to raise an event if the domain controller (DC) assumes the ISTG server role. The event indicates that the monitored computer has assumed that role. The default is Yes.
Event severity when DC assumes this role	Set the severity level, from 1 to 40, to indicate the importance of an event in which the DC assumes the ISTG server role. The default is 30.
Raise event when DC relinquishes this role?	If you enabled job delegation, set to Yes to raise an event if the DC gives up the ISTG server role. The event indicates that the monitored computer has relinquished that role. The default is Yes.
Event severity when DC relinquishes this role	Set the severity level, from 1 to 40, to indicate the importance of an event in which the DC relinquishes the ISTG server role. The default is 30.
Event Notification	
Raise event when connectivity to domain controller fails?	Select Yes to raise an event if connectivity to the DC fails. The default is Yes.

Parameter	How to Set It
Event severity when domain controller down	Set the severity level, from 1 to 40, to indicate the importance of an event in which connectivity to the DC fails. The default is 5.
Data Collection	
Collect data for site connectivity percentage?	Select Yes to collect data for charts and reports. If enabled, data collection returns the connectivity percentage for the site. For example, if 9 of the 10 domain controllers in the site are accessible, connectivity is 90%. The default is unselected.

3.11 DomainConnectivity

Use this Knowledge Script to monitor the connectivity between a domain controller and selected domains included in the scope of the target: domains included in the run target or selected on the Objects tab. This script raises an event if the connection to any trusted domain fails.

Trust relationships are fragile, and problems with them are hard to diagnose. Broken trusts prevent users from logging in or accessing cross-domain resources.

The most common reason for broken trust relationships are:

- No domain controllers are available for a remote domain.
- Trust password is not synchronized properly.

3.11.1 Resource Objects

Active Directory trusted domain

3.11.2 Default Schedule

The default interval for this script is **Every 30 minutes**.

3.11.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Raise event if job fails	
Event severity when job fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the DomainConnectivity job fails. The default is 35.
Monitor connectivity to selected domains	
Enable job delegation?	Select Yes to enable the delegation of the job to another server where appropriate. If enabled, runs the job on the selected computer that holds the server role that you selected for the *Delegate forest-wide monitoring to the...* parameter. The default is unselected. For more information, see "AD Knowledge Script Job Delegation" on page 90.
Delegate domain-wide monitoring to the	Select the server role to which the job should be delegated: **Primary Domain Controller (PDC)**, **Infrastructure Master**, or **RID Master**. The default is PDC.
Raise event when DC assumes this role?	If you enabled job delegation, set to Yes to raise an event if the DC assumes the server role you selected for the *Delegate domain-wide monitoring to the...* parameter. The event indicates that the monitored computer has assumed the selected role. The default is Yes.
Event severity when DC assumes this role	Set the severity level, from 1 to 40, to indicate the importance of an event in which the DC assumes the role you selected for the *Delegate domain-wide monitoring to the...* parameter. The default is 30.

Parameter	How to Set It
Raise event when DC relinquishes this role?	If you enabled job delegation, set to Yes to raise an event if the DC gives up the server role you selected for the *Delegate domain-wide monitoring to the...* parameter. The event indicates that the monitored computer has relinquished the selected role. The default is Yes.
Event severity when DC relinquishes this role	Set the severity level, from 1 to 40, to indicate the importance of an event in which the DC relinquishes the role you selected for the *Delegate domain-wide monitoring to the...* parameter. The default is 30.
Event Notification	
Raise event when domain connectivity fails?	Select **Yes** to raise an event if connectivity to a domain fails. The default is Yes.
Event severity when domain connectivity fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which connectivity to a domain fails. The default is 10.
Data Collection	
Collect data for connection status?	Select Yes to collect data for charts and reports. If enabled, data collection returns: • 100 – the connection to a trusted domain was successful, or • 0 – the connection failed. The default is unselected.

3.12 EnumerateSites

Use this Knowledge Script to monitor changes to sites in an Active Directory forest. This script raises an event if any changes since the last job iteration are detected.

3.12.1 Resource Objects

Active Directory domain controller

3.12.2 Default Schedule

The default interval for this script is **Every 24 hours**.

3.12.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Raise event if job fails	
Event severity when job fails	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the EnumerateSites job fails. The default is 35.
Monitor the number of sites in forest	
Enable job delegation?	Select Yes to enable the delegation of the job to another server where appropriate. If enabled, runs the job on the selected computer that holds the server role (Domain Master or Schema Master) that you selected for the *Delegate forest-wide monitoring to the...* parameter (see below). The default is unselected. For more information, see "AD Knowledge Script Job Delegation" on page 90.
Delegate forest-wide monitoring to the	Select the server role to which the job should be delegated: **Domain Master** or **Schema Master**. The default is Domain Master.
Raise event when DC assumes this role?	If you enabled job delegation, set to Yes to raise an event if the DC assumes the server role you selected for the *Delegate forest-wide monitoring to the...* parameter. The event message indicates that the monitored computer has assumed the selected role. The default is Yes.
Event severity when DC assumes this role	Set the severity level, from 1 to 40, to indicate the importance of an event in which the DC assumes the role you selected for the *Delegate forest-wide monitoring to the...* parameter. The default is 30.
Raise event when DC relinquishes this role?	If you enabled job delegation, set to Yes to raise an event if the DC gives up the server role you selected for the *Delegate forest-wide monitoring to the...* parameter. The event message indicates that the monitored computer has relinquished the selected role. The default is Yes.
Event severity when DC relinquishes this role	Set the severity level, from 1 to 40, to indicate the importance of an event in which the DC relinquishes the role you selected for the *Delegate forest-wide monitoring to the...* parameter. The default is 30.
Event Notification	

Parameter	How to Set It
Raise event when changes to sites occur?	Select Yes to raise an event if changes occur to sites in the forest. The default is Yes.
Event severity when number of sites changes	Set the severity level, from 1 to 40, to indicate the importance of an event in which changes occur to sites in the forest. The default is 25.
Data Collection	
Collect data for number of sites in forest?	Select Yes to collect data for charts and reports. If enabled, data collection returns the number of sites. The default is unselected.

3.13 EventLog

Use this Knowledge Script to monitor the Directory Service Log for Active Directory error and entries. You can configure this script to scan the log only for entries that match a set of filtering criteria.

This script does not fully rescan the event log each time it runs. All event-log entries that match the filtering criteria are returned in the event or data point detail message.

You can restrict the types of log entries that generate an event by using the *Filtering* parameters:

- Use the *Event Type* parameters to search only certain types of events, such as Warning events.
- Use the *Other* parameters to search only for specific information, such as events associated with a specific user or computer name.

NOTE:

- Only the most recent batch of events can be viewed in the data point detail message. For example, assume you set the script to scan all previous entries in the event log and list ten matching entries in each event detail message. When the script runs, 30 entries are found that match your filtering criteria. In this case, the script would create three child events for the interval. Each child event would have ten entries: the oldest matching entries in one child event batch, the second oldest in a second batch, and the most recent in a third batch. If this same job is collecting data and you view the detail message for the interval, only the entries from the third child event (Batch 3) are displayed.
- If you are notified of an error with **Event ID: 1311**, it is extremely important to follow the instructions provided in the error message to resolve this problem. The details that identify this event are as follows:
  - Event Type: `Error`
  - Event Source: `NTDS KCC`
  - Category: `Knowledge Consistency Checker`
  - Event ID: `1311`

3.13.1 Resource Object

Active Directory domain controller

3.13.2 Default Schedule

The default interval for this script is **Every 15 minutes**.

3.13.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
General Settings	
Raise event if job fails	
Event severity when job fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the EventLog job fails. The default is 35.

Description	How to Set It
Monitor Directory Service log events	
Start with events in past N hours	Set this parameter to control checking for the first job iteration. After the first iteration, checking of the log is incremental: • **-1**–all the existing log entries • **n**–entries from the past *n* hours (8 for the past 8 hours, 50 for the past 50 hours, etc.) • **0**–no previous entries (only search from the present moment forward) The default is 0.
Filtering	
Event Types	
Error	Select Yes to monitor Error entries. The default is Yes.
Warning	Select Yes to monitor Warning entries. The default is unselected.
Information	Select Yes to monitor Information entries. The default is unselected.
Success Audit	Select Yes to monitor Success Audit entries. The default is unselected.
Failure Audit	Select Yes to monitor Failure Audit entries. The default is unselected.
Other	
Filter – Source	To monitor events generated by a particular source, enter an appropriate search string. This script looks for matching entries in the Event Log's **Source** field. Multiple strings can be entered separated by commas. The search string can contain criteria used to include entries, exclude entries, or both. Separate the include and exclude criteria with a colon (:). If you are specifying only include criteria, the colon is not necessary.
Filter – Category	To monitor events in a particular category, such as Server or Logon, enter an appropriate search string. This script looks for matching entries in the Event Log's **Category** field. Multiple strings can be entered separated by commas. The search string can contain criteria used to include entries, exclude entries, or both. Separate the include and exclude criteria with a colon (:). If you are specifying only include criteria, the colon is not necessary.
Filter – Event ID	To monitor particular event IDs, enter an appropriate search string or ID range, for example, 100-2000. This script looks for matching entries in the Event Log's **Event** field. Multiple IDs and ranges can be entered, separated by commas and no spaces. For example: `1,2,10-15,202`. The search string can contain criteria used to include entries, exclude entries, or both. Separate the include and exclude criteria with a colon (:). If you are specifying only include criteria, the colon is not necessary.
Filter – User	To monitor events associated with a particular user, enter an appropriate search string, for example, `<domain name>\<user name>`. This script looks for matching entries in the Event Log's **User** field. Multiple strings can be entered separated by commas. The search string can contain criteria used to include entries, exclude entries, or both. Separate the include and exclude criteria with a colon (:). If you are specifying only include criteria, the colon is not necessary.

Description	How to Set It
Filter – Computer	To monitor events generated by a particular computer, enter an appropriate search string. This script looks for matching entries in the Event Log's **Computer** field. Multiple strings can be entered separated by commas. The search string can contain criteria used to include entries, exclude entries, or both. Separate the include and exclude criteria with a colon (:). If you are specifying only include criteria, the colon is not necessary.
Filter – Description	To monitor events with a particular detail description or containing keywords in the description, enter an appropriate search string. This script looks for matching entries in the Event Log's **Description** field. Multiple strings can be entered separated by commas. The search string can contain criteria used to include entries, exclude entries, or both. Separate the include and exclude criteria with a colon (:). If you are specifying only include criteria, the colon is not necessary.
Event Notification	
Raise event if new log entries found?	Select Yes to raise an event if new log entries are found. The default is Yes.
Maximum number of entries per event message	Specify the maximum number of entries to be recorded into each event's detail message. If this script finds more entries from the log than can be put into one event message, it will return multiple events to report all the outstanding entries in the log. The default is 1 entry.
Event severity when new event log entries found	Set the event severity level, from 1 to 40, to indicate the importance of an event in which event log entries are found. The default is 10.
Data Collection	
Collect data for number of matching entries?	Select Yes to collect data for charts and reports. If enabled, data collection returns the number of Event Log entries that match your filtering criteria. Additional information is supplied in the data detail message. The default is unselected.

3.14 EventLog (NetLogon)

Use this Knowledge Script to monitor the Windows Event Log for Active Directory entries associated with the NetLogon service. You can configure this script to scan the log only for entries that match a set of filtering criteria.

This script does not fully rescan the event log each time it runs. All event-log entries that match the filtering criteria are returned in the event or data point detail message.

You can restrict the types of log entries that generate an event by using the *Filtering* parameters:

- Use the *Event Type* parameters to search only certain types of events, such as Warning events.
- Use the *Other* parameters to search only for specific information, such as events associated with a specific user or computer name.

NOTE: Only the most recent batch of events can be viewed in the data point detail message. For example, assume you set this script to scan all previous entries in the event log and list ten matching entries in each event detail message. When the script runs, 30 entries are found that match your filtering criteria. In this case, the script would create three child events for the interval.

Each child event would have ten entries: the oldest matching entries in one child event batch, the second oldest in a second batch, and the most recent in a third batch.

If this same job is collecting data and you view the detail message for the interval, only the entries from the third child event (Batch 3) are displayed.

3.14.1 Resource Objects

Active Directory domain controller

3.14.2 Default Schedule

The default interval for this script is **Every 15 minutes**.

3.14.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
General Settings	
Raise event if job fails	
Event severity when job fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the EventLog (NetLogon) job fails. The default is 35.
Monitor Windows System log for NetLogon events	

Description	How to Set It
Start with events in past	Set this parameter to control checking for the first job iteration. After the first iteration, checking of the log is incremental: • **-1**–all the existing log entries • **n**–entries from the past *n* hours (8 for the past 8 hours, 50 for the past 50 hours, etc.) • **0**–no previous entries (only search from the present moment forward) The default is 0.
Filtering	
Event Types	
Error	Select Yes to monitor Error entries. The default is Yes.
Warning	Select Yes to monitor Warning entries. The default is Yes.
Information	Select Yes to monitor Information Entries. The default is unselected.
Other	
Filter – Source	To monitor events generated by a particular source, enter an appropriate search string. This script looks for matching entries in the Event Log's **Source** field. Multiple strings can be entered separated by commas. The search string can contain criteria used to include entries, exclude entries, or both. Separate the include and exclude criteria with a colon (:). If you are specifying only include criteria, the colon is not necessary.
Filter – Category	To monitor events in a particular category, such as Server or Logon, enter an appropriate search string. This script looks for matching entries in the Event Log's **Category** field. Multiple strings can be entered separated by commas. The search string can contain criteria used to include entries, exclude entries, or both. Separate the include and exclude criteria with a colon (:). If you are specifying only include criteria, the colon is not necessary.
Filter – Event ID	To monitor particular event IDs, enter an appropriate search string or ID range, for example, 100-2000. This script looks for matching entries in the Event Log's **Event** field. Multiple IDs and ranges can be entered, separated by commas and no spaces. For example: `1,2,10-15,202`. The search string can contain criteria used to include entries, exclude entries, or both. Separate the include and exclude criteria with a colon (:). If you are specifying only include criteria, the colon is not necessary.
Filter – User	To monitor events associated with a particular user, enter an appropriate search string, for example, `<domain name>\<user name>`. This script looks for matching entries in the Event Log's **User** field. Multiple strings can be entered separated by commas. The search string can contain criteria used to include entries, exclude entries, or both. Separate the include and exclude criteria with a colon (:). If you are specifying only include criteria, the colon is not necessary.
Filter – Computer	To monitor events generated by a particular computer, enter an appropriate search string. This script looks for matching entries in the Event Log's **Computer** field. Multiple strings can be entered separated by commas. The search string can contain criteria used to include entries, exclude entries, or both. Separate the include and exclude criteria with a colon (:). If you are specifying only include criteria, the colon is not necessary.

Description	How to Set It
Filter – Description	To monitor events with a particular detail description or containing keywords in the description, enter an appropriate search string. This script looks for matching entries in the Event Log's **Description** field. Multiple strings can be entered separated by commas. The search string can contain criteria used to include entries, exclude entries, or both. Separate the include and exclude criteria with a colon (:). If you are specifying only include criteria, the colon is not necessary.
Event Notification	
Raise event if new log entries found?	Select Yes to raise an event if new log entries are found. The default is Yes.
Maximum number of entries per event message	Specify the maximum number of entries to be recorded into each event's detail message. If this script finds more entries from the log than can be put into one event message, it will return multiple events to report all of the outstanding entries in the log. The default is 1 entry.
Event severity when new event log entries found	Set the severity level, from 1 to 40, to indicate the importance of an event in which new log entries are fund. The default is 10.
Data Collection	
Collect data for number of matching entries?	Select Yes to collect data for charts and reports. If enabled, data collection returns the number of Event Log entries that match your filtering criteria. Additional information is supplied in the data detail message. The default is unselected.

3.15 EventLog (W32Time)

Use this Knowledge Script to monitor the Windows Event Log for Active Directory entries associated with the Windows Time service (`W32Time`). You can configure this script to scan the log only for entries that match a set of filtering criteria.

This script does not fully rescan the event log each time it runs. All event-log entries that match the filtering criteria are returned in the event or data point detail message.

You can restrict the types of log entries that generate an event by using the *Filtering* parameters:

- Use the *Event Type* parameters to search only certain types of events, such as Warning events.
- Use the *Other* parameters to search only for specific information, such as events associated with a specific user or computer name.

NOTE: Only the most recent batch of events can be viewed in the data point detail message. For example, assume you set this script to scan all previous entries in the event log and list ten matching entries in each event detail message.

When the script runs, 30 entries are found that match your filtering criteria. In this case, the script would create three child events for the interval. Each child event would have ten entries: the oldest matching entries in one child event batch, the second oldest in a second batch, and the most recent in a third batch.

If this same job is collecting data and you view the detail message for the interval, only the entries from the third child event (Batch 3) are displayed.

3.15.1 Resource Objects

Active Directory domain controller

3.15.2 Default Schedule

The default interval for this script is **Every 15 minutes**.

3.15.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Raise event if job fails	
Event severity when job fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the EventLog (W32Time) job fails. The default is 35.
Monitor Windows System log for time synchronization events	

Parameter	How to Set It
Start with events in past	Set this parameter to control checking for the first job iteration. After the first iteration, checking of the log is incremental: • **-1**–all the existing log entries • **n**–entries from the past *n* hours (8 for the past 8 hours, 50 for the past 50 hours, etc.) • **0**–no previous entries (only search from the present moment forward) The default is 0.
Filtering	
Event Types	
Error	Select Yes to monitor Error entries. The default is Yes.
Warning	Select Yes to monitor Warning entries. The default is Yes.
Information	Select Yes to monitor Information entries. The default is unselected.
Other	
Filter – Source	To monitor events generated by a particular source, enter an appropriate search string. This script looks for matching entries in the Event Log's **Source** field. Multiple strings can be entered separated by commas. The search string can contain criteria used to include entries, exclude entries, or both. Separate the include and exclude criteria with a colon (:). If you are specifying only include criteria, the colon is not necessary.
Filter – Category	To monitor events in a particular category, such as Server or Logon, enter an appropriate search string. This script looks for matching entries in the Event Log's **Category** field. Multiple strings can be entered separated by commas. The search string can contain criteria used to include entries, exclude entries, or both. Separate the include and exclude criteria with a colon (:). If you are specifying only include criteria, the colon is not necessary.
Filter – Event ID	To monitor particular event IDs, enter an appropriate search string or ID range, for example, 100-2000. This script looks for matching entries in the Event Log's **Event** field. Multiple IDs and ranges can be entered, separated by commas and no spaces. For example: `1,2,10-15,202`. The search string can contain criteria used to include entries, exclude entries, or both. Separate the include and exclude criteria with a colon (:). If you are specifying only include criteria, the colon is not necessary.
Filter – User	To monitor events associated with a particular user, enter an appropriate search string, for example, `<domain name>\<user name>`. This script looks for matching entries in the Event Log's **User** field. Multiple strings can be entered separated by commas. The search string can contain criteria used to include entries, exclude entries, or both. Separate the include and exclude criteria with a colon (:). If you are specifying only include criteria, the colon is not necessary.
Filter – Computer	To monitor events generated by a particular computer, enter an appropriate search string. This script looks for matching entries in the Event Log's **Computer** field. Multiple strings can be entered separated by commas. The search string can contain criteria used to include entries, exclude entries, or both. Separate the include and exclude criteria with a colon (:). If you are specifying only include criteria, the colon is not necessary.

Parameter	How to Set It
Filter – Description	To monitor events with a particular detail description or containing keywords in the description, enter an appropriate search string. This script looks for matching entries in the Event Log's **Description** field. Multiple strings can be entered separated by commas. The search string can contain criteria used to include entries, exclude entries, or both. Separate the include and exclude criteria with a colon (:). If you are specifying only include criteria, the colon is not necessary.
Event Notification	
Raise event if new log entries found?	Select Yes to raise an event if new log entries are found. The default is Yes.
Maximum number of entries per event message	Specify the maximum number of entries to be recorded into each event's detail message. If this script finds more entries from the log than can be put into one event message, it returns multiple events to report all the outstanding entries in the log. The default is 1 entry.
Event severity when new event log entries found	Set the event severity level, from 1 to 40, to indicate the importance of an event in which new log entries are found. The default is 10.
Data Collection	
Collect data for number of matching entries?	Select Yes to collect data for charts and reports. If enabled, data collection returns the number of Event Log entries that match your filtering criteria. Additional information is supplied in the data detail message. The default is unselected.

3.16 FSMOChange

Use this Knowledge Script to monitor changes to Flexible Single Master Operations (FSMO) roles in an Active Directory forest. This script raises an event if the domain controller for any role is changed.

TIP: Carefully monitor any FSMO role-holder movements to help correlate performance issues with improper role-holder placement.

3.16.1 Resource Objects

Active Directory domain

3.16.2 Default Schedule

The default interval for this script is **Every 30 minutes**.

3.16.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Raise event if job fails	
Event severity when job fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the FSMOChange job fails. The default is 35.
Monitor changes to FSMO roles	
Enable job delegation?	Select Yes to enable the delegation of the job to another server where appropriate. If enabled, runs the job on the selected computer that holds the server role that you selected for the *Delegate domain-wide monitoring to the...* parameter. The default is unselected. For more information, see "AD Knowledge Script Job Delegation" on page 90.
Delegate domain-wide monitoring to the	Select the server role to which the job should be delegated: **Primary Domain Controller (PDC)**, **Infrastructure Master**, or **RID Master**. The default is PDC.
Raise event when DC assumes this role?	If you enabled job delegation, set to Yes to raise events if the DC assumes the server role you selected for the *Delegate domain-wide monitoring to the...* parameter. The event indicates that the monitored computer has assumed the selected role. The default is Yes.
Event severity when DC assumes this role	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the DC assumes the role you selected for the *Delegate domain-wide monitoring to the...* parameter. The default is 30.
Raise event when DC relinquishes this role?	If you enabled job delegation, set to Yes to raise events if the DC gives up the server role you selected for the *Delegate domain-wide monitoring to the...* parameter. The event indicates that the monitored computer has relinquished the selected role. The default is Yes.

Parameter	How to Set It
Event severity when DC relinquishes this role	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the DC relinquishes the role you selected for the *Delegate domain-wide monitoring to the...* parameter. The default is 30.
Event Notification	
Raise event if change to FSMO roles detected?	Select Yes to raise an event if changes to FSMO roles are detected. The default is Yes.
Event severity when change detected	Set the severity level, from 1 to 40, to indicate the importance of an event in which changes to FSMO roles are detected. The default severity level is 20.
Data Collection	
Collect data for changes to FSMO roles?	Select Yes to collect data for charts and reports. If enabled, data collection returns: • 100 – no change to the FSMO roles detected, or • 0 – change to FSMO role detected. The default is unselected.

3.17 FSMOHealth

Use this Knowledge Script to monitor access to the domain controllers that have been given any Flexible Single Master Operations (FSMO) role. FSMO roles include:

- Schema Master
- Domain Naming Master
- Primary Domain Controller (PDC) emulator
- Relative ID (RID) Master
- Infrastructure Master

This script uses the Active Directory Service Interface (ADSI) and attempts to connect to each domain controller that is serving an FSMO role. In addition, this script raises an event if the connection fails for any domain controller holding an Operations Master role. The event detail message identifies the domain controller that failed to respond and its FSMO role.

3.17.1 Job Delegation and the FSMOHealth Knowledge Script

The Knowledge Script job delegation feature is implemented differently in this script than in other scripts. Unlike other scripts, FSMOHealth performs a connectivity check. For obvious reasons, you do not want it merely to perform a connectivity self-check on the domain controller (DC) to which the job has been delegated.

When enabling job delegation for AD_FSMOHealth, you are not asked to select the role holder to which the monitoring job is to be delegated. Instead, this script runs on every domain FSMO role holder: the IM, PDC, and RID. If one DC in the domain holds all of the roles, another DC in the domain is selected to connect to the Operations Master.

NOTE: Having only one DC in a domain is not a recommended Active Directory practice. Redundancy for the domain partition is recommended, and a lack of redundancy for a domain partition is identified by the replication monitoring feature of the ServerHealth Knowledge Script.

3.17.2 Deploying this Script Without Job Delegation

Deploy this script to one DC per domain, selecting a DC that does not hold any of the domain FSMO roles. If no such DC exists (say, if you have three or fewer DCs and each holds a domain FSMO role), then deploy this script to every DC. As they each hold a domain FSMO role, they will check each other.

Exercise care in selecting the DCs to be monitored and deploying the job to those DCs. Consider creating a custom server group for this script unless you enable job delegation. If you change the domain FSMO role holders, modify the server group accordingly.

3.17.3 Resource Objects

Active Directory domain

3.17.4 Default Schedule

The default interval for this script is **Every 10 minutes**.

3.17.5 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Raise event if job fails	
Event severity when job fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the FSMOHealth job fails. The default is 35.
Monitor connectivity to FSMO role holders	
Enable job delegation?	Select Yes to enable the delegation of the job to another server where appropriate. If enabled, the runs job on each DC that holds a domain FSMO role. The default is unselected. For more information, see "AD Knowledge Script Job Delegation" on page 90.
Raise event when DC assumes this role?	If you enabled job delegation, set to **Yes** to raise events if the DC assumes a domain FSMO role. The event indicates that the monitored computer has assumed a domain FSMO role. The default is Yes.
Event severity when DC assumes this role	Set the severity level, from 1 to 40, to indicate the importance of an event in which the DC assumes a domain FSMO role. The default is 30.
Raise event when DC relinquishes this role?	If you enabled job delegation, set to **Yes** to raise events if the DC gives up a domain FSMO role. The event indicates that the monitored computer has relinquished the selected role. The default is Yes.
Event severity when DC relinquishes this role	Set the severity level, from 1 to 40, to indicate the importance of an event in which the DC relinquishes a domain FSMO role. The default is 30.
Event Notification	
Raise event if domain controller inaccessible?	Select Yes to raise an event if a DC that holds a FSMO role is inaccessible. The default is Yes.
Event severity when domain controller inaccessible	Set the severity level, from 1 to 40, to indicate the importance of an event in which a DC that holds a FSMO role is inaccessible. The default is 10.
Data Collection	
Collect data for inaccessible DC and its role?	Select Yes to collect data for charts and reports. If enabled, data collection returns a value of 100 if there is no change to the FMSO roles, or a value of 0 if there has been a change during the interval. The default is unselected.

3.18 FSMOPlacement

Use this Knowledge Script to monitor the placement of a Flexible Single Master Operations (FSMO) role.

Active Directory follows Microsoft Best Practices for the placement of FSMO roles:

- The FSMO role of the infrastructure master must not host a global catalog unless all domain controllers in the domain of the Infrastructure Master are hosting global catalogs.
- The Domain-Naming Master must host a global catalog.

This script raises an event if the placement of the FSMO role violates either rule.

3.18.1 Resource Objects

Active Directory domain

3.18.2 Default Schedule

The default interval for this script is **Every 4 hours**.

3.18.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Raise event if job fails	
Event severity when job fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the FSMOPlacement job fails. The default is 35.
Monitor FSMO role placement	
Enable job delegation?	Select Yes to enable the delegation of the job to another server where appropriate. If enabled, runs the job on the selected computer that holds the server role that you selected for the *Delegate domain-wide monitoring to the...* parameter. The default is unselected. For more information, see "AD Knowledge Script Job Delegation" on page 90.
Delegate domain-wide monitoring to the	Select the server role to which the job should be delegated: **Primary Domain Controller (PDC)**, **Infrastructure Master**, or **RID Master**. The default is PDC.
Raise event when DC assumes this role?	If you enabled job delegation, set to **Yes** to raise events if the DC assumes the server role you selected for the *Delegate domain-wide monitoring to the...* parameter. The event indicates that the monitored computer has assumed the selected role. The default is Yes.
Event severity when DC assumes this role	Set the severity level, from 1 to 40, to indicate the importance of an event in which the DC assumes the role you selected for the *Delegate domain-wide monitoring to the...* parameter. The default is 30.

Parameter	How to Set It
Raise event when DC relinquishes this role?	If you enabled job delegation, set to **Yes** to raise events if the DC gives up the server role you selected for the *Delegate domain-wide monitoring to the...* parameter. The event indicates that the monitored computer has relinquished the selected role. The default is Yes.
Event severity when DC relinquishes this role	Set the severity level, from 1 to 40, to indicate the importance of an event in which the DC relinquishes the role you selected for the *Delegate domain-wide monitoring to the...* parameter. The default is 30.
Event Notification	
Raise event if role placement invalid?	Select Yes to raise an event if the FSMO role placement is invalid. The default is Yes.
Event severity when role placement invalid	Set the severity level, from 1 to 40, to indicate the importance of an event in which the FSMO role placement is invalid. The default is 10.
Data Collection	
Collect data for role placement status (valid or invalid)?	Select Yes to collect data for charts and reports. If enabled, data collection returns: • 100 – the FMSO role placement is valid, or • 0 – a problem with role placement was found. The default is unselected.

3.19 GlobalCatalogChange

Use this Knowledge Script to monitor changes to the list of global catalog (GC) servers defined in the forest. This script raises an event if new GC servers are added or any GC servers are run.

TIP: Global catalog placement is critical to Active Directory health, especially in branch office deployments. Carefully monitor GC placement to ensure that clients can always log in and use Microsoft Exchange, even if a WAN link is down. Proper GC placement also prevents significant accidental WAN traffic because clients will go to remote GCs if a local GC is not present.

3.19.1 Resource Objects

Active Directory domain controller

3.19.2 Default Schedule

The default interval for this script is **Every 4 hours**.

3.19.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Raise event if job fails	
Event severity when job fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the GlobalCatalogChange job fails. The default is 35.
Monitor global catalog server changes	
Enable job delegation?	Select Yes to enable the delegation of the job to another server where appropriate. If enabled, runs the job on the selected computer that holds the server role (Domain Master or Schema Master) that you selected for the *Delegate forest-wide monitoring to the...* parameter. The default is unselected. For more information, see "AD Knowledge Script Job Delegation" on page 90.
Delegate forest-wide monitoring to the	Select the server role to which the job should be delegated: **Domain Master** or **Schema Master**. The default is Domain Master.
Raise event when DC assumes this role?	If you enabled job delegation, set to **Yes** to raise events if the DC assumes the server role you selected for the *Delegate forest-wide monitoring to the...* parameter. The event indicates that the monitored computer has assumed the selected role. The default is Yes.
Event severity when DC assumes this role	Set the severity level, from 1 to 40, to indicate the importance of an event in which the DC assumes the role you selected for the *Delegate forest-wide monitoring to the...* parameter. The default is 30.
Raise event when DC relinquishes this role?	If you enabled job delegation, set to **Yes** to raise events if the DC gives up the server role you selected for the *Delegate forest-wide monitoring to the...* parameter. The event indicates that the monitored computer has relinquished the selected role. The default is Yes.

Parameter	How to Set It
Event severity when DC relinquishes this role	Set the severity level, from 1 to 40, to indicate the importance of an event in which the DC relinquishes the role you selected for the *Delegate forest-wide monitoring to the...* parameter. The default is 30.
Event Notification	
Raise event if global catalog server changes detected?	Select Yes to raise an event if GC servers are added or run. The default is Yes.
Event severity when changes detected	Set the severity level, from 1 to 40, to indicate the importance of an event in which GC servers are added or run. The default is 25.
Data Collection	
Collect data for global catalog server changes?	Select Yes to collect data for charts and reports. If enabled, data collection returns: • 0 – no changes to the list of global catalog servers, or • 1 – there have been changes to the list of global catalog servers. The default is unselected.

3.20 GlobalCatalogHealth

Use this Knowledge Script to monitor access to the global catalog (GC) servers defined in the forest. This script retrieves a list of all GC servers within the site or forest specified in the *Site list* parameter, and tries to connect to them using ADSI (Active Directory Service Interfaces). In addition, this script raises an event if the connection fails for any domain controller hosting a GC.

3.20.1 Resource Objects

Active Directory domain controller

3.20.2 Default Schedule

The default interval for this script is **Every 10 minutes**.

3.20.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Raise event if job fails	
Event severity when job fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the GlobalCatalogHealth job fails. The default is 35.
Monitor connectivity to global catalog servers	
Scope of global catalog monitoring	Select **site(s)** or **forest** to indicate the scope within which you want to monitor your global catalog servers.
Site list (comma-separated, no spaces)	Specify a list of sites to monitor. Separate names by commas and no spaces. The list can contain no more than 4096 characters.
Full path to file with list of sites	You can use a text file that contains a list of sites, rather than using the previous parameter. Specify the path to that file here. The path can be to a file on the computer where the AppManager agent is installed (for example, `C:\AMAgent\sitelist`), or a UNC path if the file exists on a different computer (for example, `\\Server1\SiteLists\sitelist`). The file should contain one site per line. The AppManager agent must have read permission for the file.
Enable job delegation?	Select Yes to enable the delegation of the job to another server where appropriate. If enabled, runs the job on the selected computer that holds the Inter-Site Topology Generator (ISTG) server role. The default is unselected. For more information, see "AD Knowledge Script Job Delegation" on page 90.
Delegate site-wide monitoring to the	Indicates the server role to which the job should be delegated, the ISTG.

Parameter	How to Set It
Raise event when DC assumes this role?	If you enabled job delegation, set to **Yes** to raise events if the domain controller (DC) assumes the ISTG server role. The event indicates that the monitored computer has assumed that role. The default is Yes.
Event severity when DC assumes this role	Set the severity level, from 1 to 40, to indicate the importance of an event in which the DC assumes the ISTG server role. The default is 30.
Raise event when DC relinquishes this role?	If you enabled job delegation, set to **Yes** to raise events if the DC gives up the ISTG server role. The event indicates that the monitored computer has relinquished that role. The default is Yes.
Event severity when DC relinquishes this role	Set the severity level, from 1 to 40, to indicate the importance of an event in which the DC relinquishes the ISTG server role. The default is 30.
Event Notification	
Raise event if connection to global catalog fails?	Select Yes to raise an event if the connection to the GC fails. The default is Yes.
Event severity when connection fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the connection to the GC fails. The default is 10.
Data Collection	
Collect data for global catalog status?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns: • Percentage of Global Catalog Servers Up % • Number of Global Catalog Servers Up GCs • Number of Global Catalog Servers Down GCs

3.21 InboundReplStat

Use this Knowledge Script to monitor the number of inbound replication requests per second in the Active Directory. This script raises an event if the number of inbound replications per second exceeds the threshold you set.

This script gathers the following Windows performance counter values for use in data collection and threshold monitoring:

Performance Objects	Counters
NTDS	DRA Inbound Values Total/sec
DirectoryServices	If data collection is enabled, values for the following counters are included in the data detail message: • DRA Inbound Objects Applied/sec • DRA Inbound Objects Filtered/sec • DRA Inbound Properties Applied/sec • DRA Inbound Properties Filtered/sec

3.21.1 Resource Objects

Active Directory domain controller

3.21.2 Default Schedule

The default interval for this script is **Every 30 minutes**.

3.21.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Raise event if job fails	
Event severity when job fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the InboundReplStat job fails. The default is 35.
Monitor inbound replication rate	
Event Notification	
Raise event if inbound replication rate exceeds threshold?	Select Yes to raise an event if the inbound replication rate exceeds the threshold you set. The default is Yes.
Threshold – Maximum inbound replication rate	Specify the maximum number of inbound replication requests allowed per second before an event is raised. The default is 120 requests per second.

Parameter	How to Set It
Event severity when replication rate exceeds threshold	Set the severity level, from 1 to 40, to indicate the importance of an event in which the inbound replication rate exceeds the threshold. The default is 20.
Data Collection	
Collect data for inbound replication rate?	Select Yes to collect data for charts and reports. If enabled, data collection returns the total inbound replication rate per second (replication requests/sec). The default is unselected.

3.22 InterReplTraffic

Use this Knowledge Script to monitor the replication traffic from the DRA (Directory Replication Agent) between Active Directory sites, sometimes referred to as inter-site replication traffic. This script raises an event if either the inbound bytes per second or the outbound bytes per second exceeds the threshold for the specified consecutive number of monitoring intervals.

This script gathers the following Windows performance counter values for use in data collection and threshold monitoring:

Performance Objects	Counters
NTDS	DRA Inbound Bytes Compressed (Between Sites, After Compression)/sec
DirectoryServices	DRA Outbound Bytes Compressed (Between Sites, After Compression)/sec
	NOTE: The same threshold applies to both counters. No computation applies.

3.22.1 Resource Objects

Active Directory domain controller

3.22.2 Default Schedule

The default interval for this script is **Every 3 hours**.

3.22.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Raise event if job fails	
Event severity when job fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the InterReplTraffic job fails. The default is 35.
Monitor intersite replication traffic	
Event Notification	
Raise event when threshold exceeded too often?	Select **Yes** to raise an event if the replication traffic threshold is exceeded too often. The default is Yes.
Threshold – Maximum inbound or outbound bytes per second	Specify the maximum number of inbound or outbound replication bytes allowed per second before an event is raised. The default is 60000 bytes per second. Inbound bytes and outbound bytes per second are monitored separately and checked against this threshold. This script raises an event if either the inbound rate or the outbound rate exceeds this threshold more than *n* times.

Parameter	How to Set It
Maximum consecutive intervals threshold can be exceeded	Specify the maximum number of consecutive intervals the inbound or outbound rate can be exceeded before raising an event. The default is 1 interval. Because replication traffic can have periodic spikes, consider setting this parameter to a higher value to filter out unnecessary events. For example, you can allow the inbound/outbound byte rate to exceed the threshold 3 to 4 times before an event is raised.
Event severity when replication traffic exceeds threshold	Set the severity level, from 1 to 40, to indicate the importance of an event in which replication traffic exceeds the threshold more than *n* times. The default is 20.
Data Collection	
Collect data for inbound and outbound bytes per second?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the number of inbound bytes per second and the number of outbound bytes per second. The default is unselected.

3.23 IntraReplTraffic

Use this Knowledge Script to monitor the replication traffic from the DRA (Directory Replication Agent) within an Active Directory site (intrasite replication traffic). You specify the maximum number of inbound or outbound bytes per second and the number of consecutive times the threshold can be exceeded before raising an event. This script raises an event if the rate of either inbound bytes per second or outbound bytes per second exceeds the threshold for the specified consecutive number of monitoring intervals.

This script gathers the following Windows performance counter values for use in data collection and threshold monitoring:

Performance Objects	Counters
NTDS	DRA Inbound Bytes Not Compressed (Within Site)/sec
DirectoryServices	DRA Outbound Bytes Not Compressed (Within Site)/sec
	NOTE: The same threshold applies to both counters. No computation applies.

3.23.1 Resource Objects

Active Directory domain controller

3.23.2 Default Schedule

The default interval for this script is **Every 10 minutes**.

3.23.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Raise event if job fails	
Event severity when job fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the IntraReplTraffic job fails. The default is 35.
Monitor intrasite replication traffic	
Event Notification	
Raise event when threshold exceeded too often?	Select **Yes** to raise an event if the replication traffic threshold is exceeded more than *n* times. The default is Yes. Use the *Maximum consecutive intervals threshold can be exceeded* parameter to determine the value of *n*.
Threshold – Maximum inbound or outbound bytes per second	Specify the maximum number of inbound or outbound replication bytes per second allowed before an event is raised. The default is 60000 bytes per second. The inbound bytes and outbound bytes per second are monitored separately and checked against this threshold. This script raises an event if either the inbound rate or the outbound rate exceeds this threshold more than *n* times.

Parameter	How to Set It
Maximum consecutive intervals threshold can be exceeded	Specify the consecutive number of intervals the inbound or outbound rate can be exceeded before raising an event. The default is 1 interval. Because replication traffic can have periodic spikes, consider setting this parameter to a higher value to filter out unnecessary events. For example, you can allow the inbound/outbound byte rate to exceed the threshold 3 to 4 times before an event is raised.
Event severity when replication traffic exceeds threshold	Set the severity level, from 1 to 40, to indicate the importance of an event in which the replication traffic threshold is exceeded more than *n* times. The default is 20.
Data Collection	
Collect data for inbound and outbound bytes per second?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the number of inbound bytes per second and the number of outbound bytes per second. The default is unselected.

3.24 KCCConnections

Use this Knowledge Script to monitor the number of Knowledge Consistency Checker (KCC) connections to and from a domain controller. The KCC is a core Active Directory service that is responsible for generating the intersite and intrasite replication topology. This script raises an event if the number of inbound or outbound KCC connections exceeds the thresholds you set.

Significant changes in the number of replication partners indicates that something significant in Active Directory replication has failed, and KCC is automatically trying to recover. If the number of partners is too great, the replication window may close before replication can complete, causing replication to fail. NetIQ Corporation recommends that no domain controller ever serve more than 50 KCC connections because of the load generated by each partner.

3.24.1 Resource Objects

Active Directory domain controller

3.24.2 Default Schedule

The default interval for this script is **Every hour**.

3.24.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Raise event if job fails	
Event severity when job fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the KCCConnections job fails. The default is 35.
Monitor number of KCC connections	
Event Notification	
Raise event if number of KCC connections exceeds threshold?	Select **Yes** to raise an event if the number of KCC connections exceeds the threshold you set. The default is Yes.
Threshold – Maximum number of inbound KCC connections	Specify the maximum number of inbound KCC connections allowed before an event is raised. The default is 10 connections.
Threshold – Maximum number of outbound KCC connections	Specify the maximum number of outbound KCC connections allowed before an event is raised. The default is 10 connections.
Event severity when either threshold exceeded	Set the severity level, from 1 to 40, to indicate the importance of an event in which a threshold is exceeded. The default is 5.
Data Collection	
Collect data for number of KCC connections?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the total number of KCC connections. The default is unselected.

3.25 KCCDisabled

Use this Knowledge Script to check if the Knowledge Consistency Checker (KCC) is enabled or disabled for a site or server. The KCC is a core Active Directory service that is responsible for generating the intersite and intrasite replication topology. You can set this script to reenable the KCC for either intersite or intrasite replication topology if it is found to be disabled.

NOTE: Enabling the KCC requires Domain Admin permission. If you want to use this Knowledge Script to enable the KCC, set the AppManager agent to run as an account with Domain Admin permission, or specify an account and password with Domain Admin permission.

3.25.1 Resource Object

Active Directory domain controller

3.25.2 Default Schedule

The default interval for this script is Every hour.

3.25.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Raise event if job fails	
Event severity when job fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the KCCDisabled job fails. The default is 35.
Monitor KCC status	
Enable job delegation?	Select **Yes** to enable the delegation of the job to another server where appropriate. If enabled, runs the job on the selected computer that holds the Inter-Site Topology Generator (ISTG) server role. The default is unselected. For more information, see "AD Knowledge Script Job Delegation" on page 90.
Delegate site-wide monitoring to the	Indicates the server role to which the job should be delegated, the ISTG.
Raise event when DC assumes this role?	If you enabled job delegation, set to **Yes** to raise events if the domain controller (DC) assumes the ISTG server role. The event indicates that the monitored computer has assumed that role. The default is Yes.
Event severity when DC assumes this role	Set the severity level, from 1 to 40, to indicate the importance of an event in which the DC assumes the ISTG server role. The default is 30.
Raise event when DC relinquishes this role?	If you enabled job delegation, set to **Yes** to raise events if the DC gives up the ISTG server role. The event indicates that the monitored computer has relinquished that role. The default is Yes.

Parameter	How to Set It
Event severity when DC relinquishes this role	Set the severity level, from 1 to 40, to indicate the importance of an event in which the DC relinquishes the ISTG server role. The default is 30.
Event Notification	
Raise event if KCC is disabled?	Select **Yes** to raise an event if the KCC is disabled. The default is Yes.
Event severity when KCC is disabled	Set the severity level, from 1 to 40, to indicate the importance of an event in which the KCC is disabled. The default is 20.
Raise event if KCC is enabled?	Select **Yes** to raise an event if the KCC is enabled. The default is unselected.
Event severity when KCC is enabled	Set the severity level, from 1 to 40, to indicate the importance of an event in which the KCC is enabled. The default is 25.
Data Collection	
Collect data for KCC status?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns: • 100 – KCC is enabled • 0 – KCC is disabled. The default is unselected.
Remediation	
Enable KCC for intrasite topology generation?	Select **Yes** to reenable the KCC for intrasite topology generation if the KCC is disabled. The default is Yes.
Enable KCC for intersite topology generation?	Select **Yes** to reenable the KCC for intersite topology generation if the KCC is disabled. The default is unselected.
Account to use to enable KCC (leave blank to use the MC account)	Specify the account to be used by AppManager for Microsoft Active Directory to reenable the KCC. Use the format `domain\user` or `user@domain`. Leave this value blank to use the managed client account.
Password for this account	Specify the password associated with the account you noted above. The maximum length allowed for the password is 32 characters.

3.26 KDCRequests

Use this Knowledge Script to monitor the rate of Kerberos Key Distribution Center (KDC) requests. The Key Distribution Center provides services for authentication and security. This script lets you set thresholds for Authentication Service (AS) requests per second and Ticket Granting Service (TGS) requests per second. In addition, this script raises an event if either threshold is exceeded.

TIP: This scripts monitors the number of authentications per second coming into the KDC. A burst indicates a surge of logon traffic.

This script gathers the following Windows performance counter values for use in data collection and threshold monitoring:

Performance Objects	Counters
NTDS	KDC AS Requests
Security System-Wide Statistics	KDC TGS Requests

3.26.1 Resource Objects

Active Directory domain controller

3.26.2 Default Schedule

The default interval for this script is **Every 30 minutes**.

3.26.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Raise event if job fails	
Event severity when job fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the KDCRequests job fails. The default is 35.
Monitor KDC request rate	
Event Notification	
Raise event if KDC request rate exceeds a threshold?	Select **Yes** to raise an event if the KDC request rate exceeds the threshold you set. The default is Yes.
Threshold – Maximum Authentication Service request rate	Specify the maximum number of Authentication Service requests allowed per second before an event is raised. The default is 20 requests per second.

Parameter	How to Set It
Threshold – Maximum Ticket Granting Service request rate	Specify the maximum number of Ticket Granting Service requests allowed per second before an event is raised. The default is 20 requests per second.
Event severity when either threshold exceeded	Set the severity level, from 1 to 40, to indicate the importance of an event in which a threshold is exceeded. The default is 20.
Data Collection	
Collect data for KDC request rates?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the rate of Authentication Service and Ticket Granting Service requests (requests/ second) during the monitoring interval. The default is unselected.

3.27 NumberOfComputers

Use this Knowledge Script to monitor the number of computers in a domain or organizational unit. This script raises an event if the number of computers exceeds the threshold you set.

3.27.1 Resource Objects

Active Directory domain or organizational unit (OU).

To monitor OUs with this script, specify `organizationalUnit` in the *Classes to include* parameter of the Discovery_ActiveDS Knowledge Script.

When run on an OU, this script monitors all computers in that OU and any child OUs. The total number of computers for an OU consists of all computers in the OU and in any child OUs.

When you run this script on a domain, the domain and all child OUs will show a job is running. However, the job runs only on the domain and not on the child OUs.

3.27.2 Default Schedule

The default interval for this script is **Every 24 hours**.

3.27.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Raise event if job fails	
Event severity when job fails	Set the severity level, from 1 to 40, to indicate the importance an event in which the NumberOfComputers job fails. The default is 35.
Monitor number of computers	
Enable job delegation?	Select **Yes** to enable the delegation of the job to another server where appropriate. If enabled, runs the job on the selected computer that holds the server role that you selected for the *Delegate domain-wide monitoring to the...* parameter. The default is unselected. For more information, see "AD Knowledge Script Job Delegation" on page 90.
Delegate domain-wide monitoring to the	Select the server role to which the job should be delegated: **Primary Domain Controller (PDC)**, **Infrastructure Master**, or **RID Master**. The default is PDC.
Raise event when DC assumes this role?	If you enabled job delegation, set to **Yes** to raise events if the DC assumes the server role you selected for the *Delegate domain-wide monitoring to the...* parameter. The event indicates that the monitored computer has assumed the selected role. The default is Yes.
Event severity when DC assumes this role	Set the severity level, from 1 to 40, to indicate the importance of an event in which the DC assumes the role you selected for the *Delegate domain-wide monitoring to the...* parameter. The default is 30.

Parameter	How to Set It
Raise event when DC relinquishes this role?	If you enabled job delegation, set to **Yes** to raise events if the DC gives up the server role you selected for the *Delegate domain-wide monitoring to the...* parameter. The event indicates that the monitored computer has relinquished the selected role. The default is Yes.
Event severity when DC relinquishes this role	Set the severity level, from 1 to 40, to indicate the importance of an event in which the DC relinquishes the role you selected for the *Delegate domain-wide monitoring to the...* parameter. The default is 30.
Event Notification	
Raise event if number of computers exceeds threshold?	Select **Yes** to raise an event if the number of computers in the domain or OU exceeds the threshold you set. The default is Yes.
Threshold – Maximum number of computers	Specify the maximum number of computers that can be in the domain or OU before an event is raised. The default is -1 computer. **NOTE:** You must change the default setting to run this script. Collect data to establish a baseline, then specify a threshold appropriate for your environment.
Event severity when number of computers exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of computers exceeds the threshold. The default is 5.
Data Collection	
Collect data for number of computers?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the number of computers detected during the monitoring interval. The default is unselected.
Number of computers to return when collecting data (0 for all computers)	Specify the number of computers you want returned when collecting data. For example, if you set this parameter to 500 and the domain contains 2,000 computers, only the first 500 computers are returned in the event message. Select 0 to return all computers. The default is 500 computers.

3.28 NumberOfDCs

Use this Knowledge Script to monitor changes to the number of domain controllers (DCs) in a domain, site, or forest.

The script retrieves the total number and names of all DCs using ADSI (Active Directory Service Interfaces). In addition, this script raises an event if any changes are detected during consecutive iterations. By default, only the local domain or site of the computer running this script is monitored. However, you can supply a list of fully qualified domain names or sites to monitor. The list overrides the local domain or site — that is, the domain of the local computer will not be monitored unless it is included in the list you supply.

This script also raises an event if the number of DCs falls below the minimum threshold or exceeds the maximum threshold.

3.28.1 Resource Objects

Active Directory domain controller

3.28.2 Default Schedule

The default interval for this script is **Every 24 hours**.

3.28.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Raise event if job fails	
Event severity when job fails	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the NumberOfDCs job fails. The default is 35.
Monitor number of domain controllers	
Monitor number of DCs in:	Select the domain, site, or forest where you want to monitor the number of DCs.

List of fully qualified domains or sites to monitor (comma-separated, no spaces)	Specify a list of fully qualified domain names or sites to monitor, separated by commas and no spaces. Leave this parameter blank to use the local domain or site of the DC.
	For example, if you selected **domains** for the *Monitor number of DCs in* parameter, you could enter:
	`us.netiq.local,dev.us.netiq.local`
	If you selected sites, enter:
	`netiqus,netiqdev`

Parameter	How to Set It
Full path to file with list of domains or sites	To instruct this script to read from a file with a list of domains or sites, rather than entering a list in the *List of fully qualified domains or sites to monitor* parameter, enter the full directory path to that file here. The path can be to a file on the computer where the AppManager agent is installed (for example, `C:\AMAgent\domainsitelist`), or a UNC path if the file exists on a different computer (for example, `\\Server1\SiteLists\domainsitelist`). The file should contain one site per line. The AppManager agent must have read permission for the file.
Enable job delegation?	Select **Yes** to enable the delegation of the job to another server where appropriate. If enabled, runs the job on the selected computer that holds the server role that you selected for the *Delegate [scope] monitoring to the...* parameter. The default is unselected. For more information, see "AD Knowledge Script Job Delegation" on page 90.
Delegate domain-wide monitoring to the	Select the server role to which the job should be delegated: **Primary Domain Controller (PDC)**, **Infrastructure Master**, or **RID Master**. The default is PDC.
Delegate site-wide monitoring to the	Indicates the server role to which the job should be delegated, the ISTG.
Delegate forest-wide monitoring to the	Select the server role to which the job should be delegated: **Domain Master** or **Schema Master**. The default is Domain Master.
Raise event when DC assumes this role?	If you enabled job delegation, set to **Yes** to raise events if the DC assumes the server role you selected for the *Delegate [scope] monitoring to the...* parameter. The event indicates that the monitored computer has assumed the selected role. The default is Yes.
Event severity when DC assumes this role	Set the severity level, from 1 to 40, to indicate the importance of an event in which the DC assumes the role you selected for the *Delegate [scope] monitoring to the...* parameter. The default is 30.
Raise event when DC relinquishes this role?	If you enabled job delegation, set to **Yes** to enable events if the DC gives up the server role you selected for the *Delegate [scope] monitoring to the...* parameter. The event indicates that the monitored computer has relinquished the selected role. The default is Yes.
Event severity when DC relinquishes this role	Set the severity level, from 1 to 40, to indicate the importance of an event in which the DC relinquishes the role you selected for the *Delegate [scope] monitoring to the...* parameter. The default is 30.
Event Notification	
Raise event if threshold exceeded or not met?	Select **Yes** to raise an event if the number of DCs exceeds or falls below the threshold you set. The default is Yes.
Threshold – Minimum number of domain controllers	Specify the minimum number of DCs that must exist to prevent an event from being raised. The default is 2 DCs.
Threshold – Maximum number of domain controllers	Specify the maximum number of DCs that can exist before an event is raised. The default is 20 DCs.
Event severity when threshold exceeded or not met	Set the severity level, from 1 to 40, to indicate the importance of ant in which the number of DCs exceeds or falls below the threshold. The default is 5.
Data Collection	

Parameter	How to Set It
Collect data for number of DCs?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the number of DCs detected during the monitoring interval. The default is unselected.

3.29 NumberOfGCs

Use this Knowledge Script to monitor changes to the number of global catalog (GC) servers in a domain, site, or forest. If the number of servers falls below the minimum threshold or exceeds the maximum threshold you set, an event is raised.

By default, only the local domain or site of the computer running this script is monitored for changes to the number of GC servers. However, you can supply a list of fully qualified domain names or sites to monitor. The list overrides the local domain or site, that is, the domain of the local computer will not be monitored unless it is included in the list you supply.

The first time the job runs, the script retrieves the total number of, and a list of, all GC servers in a domain, site, or forest.

3.29.1 Resource Objects

Active Directory domain controller

3.29.2 Default Schedule

The default interval for this script is **Every 24 hours**.

3.29.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Raise event if job fails	
Event severity when job fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the NumberOfGCs job fails. The default is 35.
Monitor number of domain controllers	
Monitor number of global catalog servers in:	Select the scope of monitoring: whether you want to monitor the number of GC servers in a domain, site, or forest.

List of fully qualified domains or sites to monitor (comma-separated, no spaces)	Specify a list of fully qualified domain names or sites to monitor, separated by commas and no spaces. Leave this parameter blank to use the local domain or site of the domain controller.
	For example, if you selected **domains** for the *Monitor number of global catalog servers in* parameter, you could enter:
	`us.netiq.local,dev.us.netiq.local`
	If you selected sites, enter:
	`netiqus,netiqdev`

Parameter	How to Set It
Full path to file with list of domains or sites	To instruct this script to read from a file with a list of domains or sites, rather than entering a list for the *List of fully qualified domains or sites to monitor* parameter, enter the full directory path to that file here. The path can be to a file on the computer where the AppManager agent is installed (for example, `C:\AMAgent\domainsitelist`), or a UNC path if the file exists on a different computer (for example, `\\Server1\SiteLists\domainsitelist`). The file should contain one site per line. The AppManager agent must have read permission for the file.
Enable job delegation?	Select **Yes** to enable the delegation of the job to another server where appropriate. If enabled, runs the job on the selected computer that holds the server role that you selected for the *Delegate [scope] monitoring to the...* parameter. The default is unselected. For more information, see "AD Knowledge Script Job Delegation" on page 90.
Delegate domain-wide monitoring to the	Select the server role to which the job should be delegated: **Primary Domain Controller (PDC)**, **Infrastructure Master**, or **RID Master**. The default is PDC.
Delegate site-wide monitoring to the	Indicates the server role to which the job should be delegated, the ISTG.
Delegate forest-wide monitoring to the	Select the server role to which the job should be delegated: **Domain Master** or **Schema Master**. The default is Domain Master.
Raise event when DC assumes this role?	If you enabled job delegation, set to **Yes** to raise events if the DC assumes the server role you selected for the *Delegate [scope] monitoring to the...* parameter. The event indicates that the monitored computer has assumed the selected role. The default is Yes.
Event severity when DC assumes this role	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the DC assumes the role you selected for the *Delegate [scope] monitoring to the...* parameter. The default is 30.
Raise event when DC relinquishes this role?	If you enabled job delegation, set to **Yes** to raise events if the DC gives up the server role you selected for the *Delegate [scope] monitoring to the...* parameter. The event indicates that the monitored computer has relinquished the selected role. The default is Yes.
Event severity when DC relinquishes this role	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the DC relinquishes the role you selected for the *Delegate [scope] monitoring to the...* parameter. The default is 30.
Event Notification	
Raise event if threshold exceeded or not met?	Select **Yes** to raise an event if the number of GC servers exceeds or falls below the threshold you sent. The default is Yes.
Threshold – Minimum number of global catalog servers	Specify the minimum number of GC servers that must exist to prevent an event from being raised. The default is 1 global catalog server.
Threshold – Maximum number of global catalog servers	Specify the maximum number of GC servers that can exist before an event is raised. The default value is 20 global catalog servers.
Event severity when threshold exceeded or not met	Set the severity level, from 1 to 40, to indicate the importance of an event in which the number of GC servers exceeds or falls below the threshold. The default is 20.
Data Collection	

Parameter	How to Set It
Collect data for number of global catalog server?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the number of GC servers detected in the interval. The first time the job runs, it also returns a list of all the GC servers. The default is unselected.

3.30 NumberOfGroups

Use this Knowledge Script to monitor the number of groups in a domain or organizational unit. This script raises an event if the number of groups exceeds the threshold you set.

3.30.1 Resource Objects

Active Directory domain or organizational unit (OU)

To monitor OUs with this script, specify `organizationalUnit` in the *Classes to include* parameter of the Discovery_ActiveDS Knowledge Script.

When run on an OU, this script monitors all groups in that OU and any child OUs. The total number of groups for an OU consists of all groups in the OU and in any child OUs.

When you run this script on a domain, the domain and all child OUs will show a job is running. However, when the script is run on a domain, the script runs only on the domain and not on the child OUs.

3.30.2 Default Schedule

The default interval for this script is **Every 24 hours**.

3.30.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Raise event if job fails	
Event severity when job fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the NumberOfGroups job fails. The default is 35.
Monitor number of groups	
Enable job delegation?	Select **Yes** to enable the delegation of the job to another server where appropriate. If enabled, runs the job on the selected computer that holds the server role that you selected for the *Delegate domain-wide monitoring to the...* parameter. The default is unselected. For more information, see "AD Knowledge Script Job Delegation" on page 90.
Delegate domain-wide monitoring to the	Select the server role to which the job should be delegated: **Primary Domain Controller (PDC)**, **Infrastructure Master**, or **RID Master**. The default is PDC.
Raise event when DC assumes this role?	If you enabled job delegation, set to **Yes** to raise events if the DC assumes the server role you selected for the *Delegate domain-wide monitoring to the...* parameter. The event indicates that the monitored computer has assumed the selected role. The default is Yes.
Event severity when DC assumes this role	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the DC assumes the role you selected for the *Delegate domain-wide monitoring to the...* parameter. The default is 30.

Parameter	How to Set It
Raise event when DC relinquishes this role?	If you enabled job delegation, set to **Yes** to raise events if the DC gives up the server role you selected for the *Delegate domain-wide monitoring to the...* parameter. The event indicates that the monitored computer has relinquished the selected role. The default is Yes.
Event severity when DC relinquishes this role	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the DC relinquishes the role you selected for the *Delegate domain-wide monitoring to the...* parameter. The default is 30.
Event Notification	
Raise event if number of groups exceeds threshold?	Select **Yes** to raise an event if the number of groups exceeds the threshold you set. The default is Yes.
Threshold – Maximum number of groups	Specify the maximum number of groups that can be in the domain, site, or forest before an event is raised. The default is -1 group. **NOTE:** You must change the default setting to run this script. Collect data to establish a baseline, then specify a threshold appropriate to your environment.
Event severity when number of groups exceeds threshold	Set the severity level, from 1 to 40, to indicate the importance of an event in which the number of groups exceeds the threshold. The default is 20.
Data Collection	
Collect data for number of groups?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the number of groups detected during the monitoring interval. the default is unselected.
Number of groups to return when collecting data (0 for all groups)	Specify the number of groups you want returned when collecting data. For example, if you set this parameter to 400 and the domain contains 700 groups, only the first 400 groups are returned. Enter 0 to return all groups. The default is 400 groups.

3.31 NumberOfObjects

Use this Knowledge Script to monitor the number of objects in a domain or organizational unit. This script raises an event if the number of objects exceeds the threshold you set.

Monitor the number of objects in your user domains to proactively detect any significant growth in the total number of objects. Large object growth is an unusual and serious event. Large growth overwhelms replication, causes high CPU on all affected domain controllers, and can create out-of-disk space conditions.

TIP: The recommended value for the Threshold – Maximum number of objects parameter is the current number of objects, plus 10% of that value.

3.31.1 Resource Objects

Active Directory domain or organizational unit (OU)

To monitor OUs with this script, specify `organizationalUnit` in the *Classes to include* parameter of the Discovery_ActiveDS Knowledge Script.

When run on an OU, this script monitors all objects in that OU and any child OUs. The total number of objects for an OU consists of all objects in the OU and in any child OUs.

When you run this script on a domain, the domain and all child OUs will show a job is running; but, in reality, the script runs only on the domain and not on the child OUs.

3.31.2 Default Schedule

The default interval for this script is **Every 24 hours**.

3.31.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Raise event if job fails	
Event severity when job fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the NumberOfObjects job fails. The default is 35.
Monitor number of objects	
Object class to check (* for all objects)	Select the type of Active Directory object to check: **domain**, **computer**, or **user**. Select an asterisk (*) to check for all objects. The default is none.
Enable job delegation?	Select **Yes** to enable the delegation of the job to another server where appropriate. If enabled, runs the job on the selected computer that holds the server role that you selected for the *Delegate domain-wide monitoring to the...* parameter. The default is unselected. For more information, see "AD Knowledge Script Job Delegation" on page 90.

Parameter	How to Set It
Delegate domain-wide monitoring to the	Select the server role to which the job should be delegated: **Primary Domain Controller (PDC)**, **Infrastructure Master**, or **RID Master**. The default is PDC.
Raise event when DC assumes this role?	If you enabled job delegation, set to **Yes** to enable events if the DC assumes the server role you selected for the *Delegate domain-wide monitoring to the...* parameter. The event indicates that the monitored computer has assumed the selected role. The default is Yes.
Event severity when DC assumes this role	Set the severity level, from 1 to 40, to indicate the importance of an event in which the DC assumes the role you selected for the *Delegate domain-wide monitoring to the...* parameter. The default is 30.
Raise event when DC relinquishes this role?	If you enabled job delegation, set to **Yes** to enable events if the DC gives up the server role you selected for the *Delegate domain-wide monitoring to the...* parameter. The event indicates that the monitored computer has relinquished the selected role. The default is Yes.
Event severity when DC relinquishes this role	Set the severity level, from 1 to 40, to indicate the importance of an event in which the DC relinquishes the role you selected for the *Delegate domain-wide monitoring to the...* parameter. The default is 30.
Event Notification	
Raise event when number of objects exceeds threshold?	Select **Yes** to raise an event if the number of objects in the organizational unit exceeds the threshold you set. The default is Yes.
Threshold – Maximum number of objects in class	Specify the maximum number of objects of the specified class that can be in the organizational unit before an event is raised. The default is -1 object. **NOTE:** Change the default setting to run this script. Collect data to establish a baseline, then specify a threshold appropriate to your environment.
Event severity when number of objects exceeds threshold	Set the severity level, from 1 to 40, to indicate the importance of an event in which the number of objects in the organizational unit exceeds the threshold. The default is 5.
Data Collection	
Collect data for number of objects?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the number of objects detected during the monitoring interval. The default is unselected.
Number of objects to return when collecting data (0 for all objects)	Specify the number of objects you want to include when collecting data. For example, if you set this parameter to 500 and the domain contains 800 objects, only the first 500 objects are returned. Enter 0 to return all objects. The default is 500 objects.

3.32 NumberOfPrintQueues

Use this Knowledge Script to monitor the number of print queues associated with the printer objects in a domain or an organizational unit. This script raises an event if the number of printer queues exceeds the threshold you set.

3.32.1 Resource Objects

Active Directory domain or organizational unit (OU)

To monitor OUs with this script, specify `organizationalUnit` in the *Classes to include* parameter of the Discovery_ActiveDS Knowledge Script.

When run on an OU, this script monitors all print queues in that OU and any child OUs. The total number of print queues for an OU consists of all print queues in the OU and in any child OUs.

When you run this script on a domain, the domain and all child OUs will show a job is running. However, when the script is run on a domain, the script runs only on the domain and not on the child OUs.

3.32.2 Default Schedule

The default interval for this script is **Every 24 hours**.

3.32.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if number of printer queues exceeds threshold?	Select **Yes** to raise an event if the number of printer queues exceeds the threshold you set. The default is Yes.
Collect data for number of printer queues?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the number of printer queues detected during the monitoring interval. The default is unselected.
Threshold – Maximum number of printer queues	Specify the maximum number of printer queues that can be in the domain or OU before an event is raised. The default is -1 printer queue. **NOTE:** Change the default setting to run this script. Collect data to establish a baseline, then specify a threshold appropriate to your environment.
Number of printer queues to return when collecting data	Specify the number of printer queues you want returned when collecting data. For example, if you set this parameter to 500 and the domain contains 800 printer queues, only the first 500 printer queues are returned. Enter 0 to return all printer queues. The default is 500 printer queues.
Event severity when number of printer queues exceeds threshold	Set the severity level, from 1 to 40, to indicate the importance of an event in which the number of printer queues exceeds the threshold. The default is 5.

3.33 NumberOfUsers

Use this Knowledge Script to monitor the number of users in a domain or organizational unit. This script raises an event if the number of users exceeds the threshold you set.

3.33.1 Resource Objects

Active Directory domain or organizational unit (OU).

To monitor OUs with this script, specify `organizationalUnit` in the *Classes to include* parameter of the Discovery_ActiveDS Knowledge Script.

When run on an OU, this script monitors all users in that OU and any child OUs. The total number of users for an OU consists of all users in the OU and in any child OUs.

When you run this script on a domain, the domain and all child OUs will show a job is running. But in reality, the script runs only on the domain and not on the child OUs.

3.33.2 Default Schedule

The default interval for this script is **Every 24 hours**.

3.33.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Raise event if job fails	
Event severity when job fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the NumberOfUsers job fails. The default is 35.
Monitor number of users	
Include contacts?	Select **Yes** to include contact objects in your count of the Number of Users. By default this script refers to security users only.
Enable job delegation?	Select **Yes** to enable the delegation of the job to another server where appropriate. If enabled, runs the job on the selected computer that holds the server role that you selected for the *Delegate domain-wide monitoring to the...* parameter. The default is unselected. For more information, see "AD Knowledge Script Job Delegation" on page 90.
Delegate domain-wide monitoring to the	Select the server role to which the job should be delegated: **Primary Domain Controller (PDC)**, **Infrastructure Master**, or **RID Master**. The default is PDC.
Raise event when DC assumes this role?	If you enabled job delegation, set to **Yes** to raise events if the DC assumes the server role you selected for the *Delegate domain-wide monitoring to the...* parameter. The event indicates that the monitored computer has assumed the selected role. The default is Yes.

Parameter	How to Set It
Event severity when DC assumes this role	Set the severity level, from 1 to 40, to indicate the importance of an event in which the DC assumes the role you selected for the *Delegate domain-wide monitoring to the...* parameter. The default is 30.
Raise event when DC relinquishes this role?	If you enabled job delegation, set to **Yes** to raise events if the DC gives up the server role you selected for the *Delegate domain-wide monitoring to the...* parameter. The event indicates that the monitored computer has relinquished the selected role. The default is Yes.
Event severity when DC relinquishes this role	Set the severity level, from 1 to 40, to indicate the importance of an event in which the DC relinquishes the role you selected for the *Delegate domain-wide monitoring to the...* parameter. The default is 30.
Event Notification	
Raise event when number of users exceeds threshold?	Select **Yes** to raise an event if the number of users in an organization unit or domain exceeds the threshold you set. The default is Yes.
Threshold – Maximum number of users	Specify the maximum number of users that can be in the domain or organizational unit before an event is raised. The default is -1 user. **NOTE:** Change the default setting to run this script. Collect data to establish a baseline, then specify a threshold appropriate to your environment.
Event severity when number of users exceeds threshold	Set the severity level, from 1 to 40, to indicate the importance of an event in which the number of users in the domain or organizational unit exceeds the threshold. The default is 5.
Data Collection	
Collect data for number of users?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the number of users detected in the interval. The default is unselected.
Number of users to return when collecting data (0 for all users)	Specify the number of users you want returned when collecting data. For example, if you set this parameter to 1000 and the domain or OU contains 10,000 users, only the first 1000 users are returned. Enter 0 to return all users. The default is 1000 users.

3.34 NumberOfUsersLocked

Use this Knowledge Script to monitor the number of locked user accounts in the selected a domain or organizational unit. This script raises an event if the number of locked user accounts exceeds the threshold you set.

You can set this script to automatically unlock any accounts that are found to be locked. You can also enter a comma-separated list of accounts to be unlocked. Leave the *List of accounts to unlock* parameter blank to unlock all locked accounts.

This script includes an option to ignore user accounts that have been disabled.

TIP: If your organization experiences a large number of locked accounts, this script can automatically reset them, thereby saving the organization roughly $50 per locked-out user, according to a common industry estimate.

3.34.1 Resource Objects

Active Directory domain or organizational unit (OU)

To monitor OUs with this script, specify `organizationalUnit` in the *Classes to include* parameter of the Discovery_ActiveDS Knowledge Script.

When run on an OU, this script monitors all locked user accounts in that OU and any child OUs. The total number of locked user accounts for an OU consists of all locked user accounts in the OU and in any child OUs.

When you run this script on a domain, the domain and all child OUs will show a job is running. However, when the script is run on a domain, the script runs only on the domain and not on the child OUs.

3.34.2 Default Schedule

The default interval for this script is **Every 24 hours**.

3.34.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Raise event if job fails	
Event severity when job fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the NumberOfUsersLocked job fails. The default is 35.
Monitor number of locked user accounts	
Omit disabled accounts?	Select **Yes** to ignore disabled user accounts when checking for locked user accounts. By default, this script includes disabled accounts when checking for locked user

Parameter	How to Set It
Enable job delegation?	Select **Yes** to enable the delegation of the job to another server where appropriate. If enabled, runs the job on the selected computer that holds the server role that you selected for the *Delegate domain-wide monitoring to the...* parameter. The default is unselected. For more information, see "AD Knowledge Script Job Delegation" on page 90.
Delegate domain-wide monitoring to the	Select the server role to which the job should be delegated: **Primary Domain Controller (PDC)**, **Infrastructure Master**, or **RID Master**. The default is PDC.
Raise event when DC assumes this role?	If you enabled job delegation, set to **Yes** to raise events if the DC assumes the server role you selected for the *Delegate domain-wide monitoring to the...* parameter. The event indicates that the monitored computer has assumed the selected role. The default is Yes.
Event severity when DC assumes this role	Set the severity level, from 1 to 40, to indicate the importance of an event in which the DC assumes the role you selected for the *Delegate domain-wide monitoring to the...* parameter. The default is 30.
Raise event when DC relinquishes this role?	If you enabled job delegation, set to **Yes** to raise events if the DC gives up the server role you selected for the *Delegate domain-wide monitoring to the...* parameter. The event indicates that the monitored computer has relinquished the selected role. The default is Yes.
Event severity when DC relinquishes this role	Set the severity level, from 1 to 40, to indicate the importance of an event in which the DC relinquishes the role you selected for the *Delegate domain-wide monitoring to the...* parameter. The default is 30.
Event Notification	
Raise event if number of locked user accounts exceeds threshold?	Select **Yes** to raise an event if the number of locked user accounts exceeds the threshold you set. The default is Yes.
Threshold – Maximum number of locked user accounts	Specify the maximum number of locked user accounts that can be in the domain naming context before an event is raised. The default is 10 locked accounts.
Event severity when number of locked accounts exceeds threshold	Set the severity level, from 1 to 40, to indicate the importance of an event in which the number of locked user accounts exceeds the threshold. The default is 5.
Data Collection	
Collect data for number of locked user accounts?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the number of locked user accounts detected in the interval. The default is unselected.
Remediation	
Unlock accounts that are locked?	Select **Yes** to automatically unlock locked user accounts. The default is unselected.
List of accounts to unlock	If you enabled the previous parameter, list specific user accounts to unlock, or leave the field blank to unlock all locked user accounts. Separate multiple entries with commas and no spaces. For example, to only unlock specific accounts, enter: `wolfpack,serge,elan` **NOTE:** Use the account name as it is displayed in the Users and Computers administrative tool. The names specified will match any part of an account name.

3.35 OutboundReplStat

Use this Knowledge Script to monitor the Active Directory outbound replication rate — the number of outbound replication requests per second. This script raises an event if the total number of outbound replication requests per second exceeds the threshold you set.

This script gathers the following Windows performance counter values for use in data collection and threshold monitoring:

Performance Objects	Counters
NTDS	DRA Outbound Values Total/sec
DirectoryServices	If data collection is enabled, values for the following counters are included in the data detail message: • DRA Outbound Objects/sec • DRA Outbound Properties/sec

3.35.1 Resource Objects

Active Directory domain controller

3.35.2 Default Schedule

The default interval for this script is **Every 30 minutes**.

3.35.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Raise event if job fails	
Event severity when job fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the OutboundReplStat job fails. The default is 35.
Monitor outbound replication rate	
Event Notification	
Raise event if outbound replication rate exceeds threshold?	Select **Yes** to raise an event if the outbound replication rate exceeds the threshold you set. The default is Yes.
Threshold – Maximum outbound replication rate	Specify the maximum number of outbound replication requests allowed per second before an event is raised. The default is 120 requests per second.

Parameter	How to Set It
Event severity when outbound replication rate exceeds threshold	Set the severity level, from 1 to 40, to indicate the importance of an event in which the outbound replication rate exceeds the threshold. The default is 20.
Data Collection	
Collect data for outbound replication rate?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the total outbound replication requests per second. The default is unselected.

3.36 PropertyWatch

Use this Knowledge Script to monitor changes to any property of any Active Directory object. This script raises an event if any Active Directory property changes for an object, and if Active Directory properties are not found or are not available.

This script monitors one property at a time. By default, it monitors the `whenChanged` property, which includes any changes to the Active Directory object.

Because there are many different types of Active Directory object properties, some properties are not supported by this script. If you try to monitor a property that is not supported by this script, the job fails and an event is raised.

3.36.1 Resource Objects

Any Windows computer

3.36.2 Default Schedule

The default interval for this script is **Every 15 minutes**.

3.36.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Raise event if job fails	
Event severity when job fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the PropertyWatch job fails. The default is 35.
Monitor property changes for an object	
LDAP path to the Active Directory object	Specify the LDAP path to the Active Directory object. For example: `LDAP://dc1.netiq.com/CN=Administrator,CN=Users, DC=dc1,DC=netiq,DC=com`

Parameter	How to Set It
Active Directory property name	Specify the name of the Active Directory property you want to monitor for changes. The default is **whenChanged**. Some valid property names are: • **isDeleted**, which indicates whether the object has been deleted. • **modifyTimeStamp**, which indicates whether the object's modification time has changed. • **USNChanged**, which indicates whether the object's Update Sequence Number has changed. • **whenCreated**, which indicates when the object was created. • **allowedChildClasses**, which lists the classes that can be created under the object. • **displayName**, which indicates the object's displayed name. For example, to monitor changes to the modification time stamp for an object, specify the `modifyTimeStamp` property name. The `USNChanged` property provides similar information but uses the USN rather than a timestamp and can be useful for monitoring replicated object properties.
Event Notification	
Raise event if object property has changed?	Select **Yes** to raise an event if the object property changes. The default is Yes.
Event severity when object property has changed	Set the severity level, from 1 to 40, to indicate the importance of an event in which the object property changes. The default is 20.
Data Collection	
Collect data for changes to object property?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns: • 100 – no property changes detected, or • 0 – a property has changed. The default is unselected.

3.37 ReadStat

Use this Knowledge Script to monitor the Active Directory read rate — the number of Active Directory reads per second. This script raises an event if the read rate exceeds the threshold you set.

If you use this script to collect data, you have three options for what is included in the data stream and data detail message:

- One data stream that records the total read rate. The data detail message describes the percentage of Active Directory reads that are being performed by various services, such as DRA, KCC, LSA, NSPI, SAM, XDS, and NTDSAPI.
- One data stream that records the total read rate, but without the detail message breakdown.
- Separate data streams that track the total number of reads per second and the number of reads per second for various services such as DRA, KCC, LSA, NSPI, SAM, XDS, and NTDSAPI.

If you collect data, keep in mind that the more data streams and details you collect, the greater the impact on your database management system and overall system performance. For example, if you choose the third data collection option, consider adjusting your archive policies or check the size of data tables in the AppManager repository more frequently.

This script gathers the following Windows performance counter values for use in data collection and threshold monitoring:

Performance Objects	Counters
NTDS DirectoryServices	For monitoring, only the following counter is used to determine whether the threshold has been crossed and an event should be raised: • DS Directory Reads/sec If data collection is enabled and data collection mode 1 or 3 is specified, values for the following counters are included in the data detail message: • DS % Reads from DRA • DS % Reads from KCC • DS % Reads from LSA • DS % Reads from NSPI • DS % Reads from SAM • DS % Reads from NTDSAPI (Windows Server 2003 and Windows Server 2008)

3.37.1 Resource Objects

Active Directory domain controller

3.37.2 Default Schedule

The default interval for this script is **Every 30 minutes**.

3.37.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Raise event if job fails	
Event severity when job fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the ReadStat job fails. The default is 35.
Monitor rate of read operations	
Event Notification	
Raise event if read rate exceeds threshold?	Select **Yes** to raise an event if the read rate exceeds the threshold you set. The default is Yes.
Threshold – Maximum reads per second	Specify the maximum number of Active Directory reads allowed per second before an event is raised. The default is 1 read per second.
Event severity when read rate exceeds threshold	Set the severity level, from 1 to 40, to indicate the importance of an event in which the read rate exceeds the threshold. The default is 20.
Data Collection	
Collect data for read rate?	Select **Yes** to collect data for charts and reports. If enabled, specify a value in the *Data collection mode* parameter. The default is unselected.
Data collection mode	Specify the type of data you want to collect. The following entries are valid: • 1 – one data stream that records the total read rate. The data detail message describes the percentage of Active Directory read operations that are performed by various Active Directory services. • 2 – one data stream that records the total read rate without any detail message. • 3 – several data streams: total read rate for all Active Directory services, and one data stream for each separate services. The default is 1 (one data stream and detail message).

3.38 ReplEventLog

Use this Knowledge Script to periodically scan the Directory Service log for Active Directory replication errors. This script raises an event if any Active Directory replication errors are found.

During the first monitoring interval, the value you specify for the *Directory Service log entries to scan* parameter determines how far back in the log to check for matching entries. As the script continues to run at subsequent intervals, it checks for any new entries created since the last time the log was checked.

You can further restrict the types of log entries that raise an event by using the *Filtering* parameters:

- Use the *Event Type* parameters to search only certain types of events, such as Warning events.
- Use the *Other* parameters to search only for specific information, such as events associated with a specific user or computer name.

Each time this script runs, it checks the Directory Service log for entries matching your selection criteria and raises an event if matching entries are found. The event detail message returns the text of the log entries found. When this script is set to collect data, it returns the number of log entries found, and the data point detail message returns the text of the log entries.

3.38.1 Resource Objects

Active Directory domain controller

3.38.2 Default Schedule

The default interval for this script is **Every hour**.

3.38.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Raise event if job fails	
Event severity when job fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the ReplEventLog job fails. The default is 35.
Monitor Directory Service log for replication events	
Raise event if matching log entries found?	Select **Yes** to raise an event if log entries are found that match the filters you set. The default is Yes.
Start with events in past	Set this parameter to control checking for the first interval, after which, checking is incremental: • **-1**–all the existing entries • **n**–the past *n* hours (8 for the past 8 hours, 50 for the past 50 hours, etc.) • **0**–no previous entries (only search from this moment on) The default is 0.

Parameter	How to Set It
Filtering	
Event Types	
Error	Select **Yes** to monitor Error entries. The default is Yes.
Warning	Select **Yes** to monitor Warning entries. The default is unselected.
Information	Select **Yes** to monitor Information entries. The default is unselected.
Success Audit	Select **Yes** to monitor Success Audit entries. The default is unselected.
Failure Audit	Select **Yes** to monitor Failure Audit entries. The default is unselected.
Other	
Filter – Category	To monitor events in a particular category, such as Server or Logon, enter an appropriate search string. This script looks for matching entries in the Directory Service Log's **Category** field. Multiple strings can be entered separated by commas. The search string can contain criteria used to include entries, exclude entries, or both. Separate the include and exclude criteria with a colon (:). If you are specifying only include criteria, the colon is not necessary.
Filter – Event ID	To monitor particular event IDs, enter an appropriate search string or ID range, for example 100-2000. This script looks for matching entries in the Directory Service Log's **Event** field. Multiple IDs and ranges can be entered separated by commas (for example: `1,2,10-15,202`). The search string can contain criteria used to include entries, exclude entries, or both. Separate the include and exclude criteria with a colon (:). If you are specifying only include criteria, the colon is not necessary.
Filter – User	To monitor events associated with a particular user, enter an appropriate search string, for example, `DomainName\UserName`. This script looks for matching entries in the Directory Service Log's **User** field. Multiple strings can be entered separated by commas. The search string can contain criteria used to include entries, exclude entries, or both. Separate the include and exclude criteria with a colon (:). If you are specifying only include criteria, the colon is not necessary.
Filter – Computer	To monitor events generated by a particular computer, enter an appropriate search string. This script looks for matching entries in the Directory Service Log's **Computer** field. Multiple strings can be entered separated by commas. The search string can contain criteria used to include entries, exclude entries, or both. Separate the include and exclude criteria with a colon (:). If you are specifying only include criteria, the colon is not necessary.
Filter – Description	To monitor events with a particular detail description or containing keywords in the description, enter an appropriate search string. This script looks for matching entries in the Directory Service Log's **Description** field. Multiple strings can be entered separated by commas. The search string can contain criteria used to include entries, exclude entries, or both. Separate the include and exclude criteria with a colon (:). If you are specifying only include criteria, the colon is not necessary.
Event Notification	

Parameter	How to Set It
Maximum number of entries per event message	Set the maximum number of Directory Service log events that can be returned in each event report. For example, if this value is set to 30 and 67 Directory Service log events are found, then three event reports are raised: two reports containing 30 events and one report containing seven events. The Message column on the **Events** tab in the Operator Console displays the number of events in each event report, the type of log the events are from, and the event report batch number. The batch number is the sequential number of the event report. Batch numbers start at 1 for each Knowledge Script iteration. The default is 1 entry.
Event severity when new log entries found	Set the severity level, from 1 to 40, to indicate the importance of an event in which new log entries are found. The default is 10.
Data Collection	
Collect data for number of matching entries found?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the number of Directory Service Log entries that match your filtering criteria. Additional information is supplied in the data detail message. The default is unselected.

3.39 ReplicationCheckByUSN

Use this Knowledge Script to monitor Active Directory replication by checking Update Sequence Numbers (USN). This script checks whether replication is occurring by comparing the domain controller's update sequence number at each interval with its value during the previous monitoring interval.

If the highest USN on the local domain controller has not been incremented between iterations, that replication is probaby not proceeding properly, and an event is raised. Because multimaster replication among peer domain controllers is such an important part of Active Directory, consider setting the job interval to run this script at least every five to ten minutes in active organizations where you make more frequent changes to Active Directory objects. If the job interval is too short, for example running every few seconds, you might raise false events.

NOTE: To use this script, specify server in the *Classes to include* parameter of the Discovery_ActiveDS Knowledge Script.

3.39.1 Resource Objects

Active Directory domain controller

3.39.2 Default Schedule

The default interval for this script is **Every 30 minutes**.

3.39.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Raise event if job fails	
Event severity when job fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the ReplicatonCheckByUSN job fails. The default is 35.
Monitor Active Directory replication by USN	
Event Notification	
Raise event if USN not incremented?	Select **Yes** to raise an event if the USN has not incremented since the last monitoring interval. The default is Yes.
Event severity when USN not incremented	Set the severity level, from 1 to 40, to indicate the importance of an event in which the USN has not incremented since the last monitoring interval. The default is 5.
Data Collection	
Collect data for replication status?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns: • 100 – replication is successful, or • 0 – the USN has not been updated and replication appears to be stale The default is unselected.

3.40 ReplicationLatency

Use this Knowledge Script to monitor Active Directory replication latency. Replication latency represents the amount of time a change made to an Active Directory partition takes to be reflected on another domain controller.

Replication latency is a significant metric in most typical service level agreements (SLAs) for Active Directory. To end-users, replication latency represents the maximum amount of time they have to wait after the Help Desk makes a requested change, such as a password reset. For example, an IT organization might want new user accounts or password resets to take effect a maximum of 30 minutes after the service-desk personnel initiate the change. This script can help you measure such service-level goals, despite the challenge of measuring replication latency through all the paths it can take.

For an environment with fewer than 30 domain controllers, you can allow this script to periodically inject a small change in the Active Directory partitions representing every DC and measure how long it takes to replicate that change to other DCs. For environments with thousands of DCs, this script allows even these large Active Directory topologies to get replication latency data with virtually no data overhead. For more information, see "Examples of How this Script Is Used: Example 1" on page 172.

This script measures the time it takes to replicate a change from Point A to Point B and compares that amount of time to the thresholds you set. Changes are injected to the replication object by updating an object property. You can set parameters to determine where to store this data, what user authentication credentials to use, and how often to inject changes to check latency.

The script defines two roles: the *Injector*, which makes the change, and the *Monitor*, which waits for the replication data to arrive. A single domain controller can be both an Injector and a Monitor, but if you define one DC as an Injector, you need to run this script on a second DC and designate it as the Monitor. The script injects a very tiny change to one object in a location you select. Every script interval, the script checks the selected folder and computes latency by reading every object and doing the following calculation:

```
Latency = Arrival time – Injection time
```

Based on the thresholds you set, this script raises an event based on the result of this calculation.

Injection frequency is determined by both the schedule and the value you set for the *Change injection frequency* parameter. For example, if this script runs every 17 minutes and the *Change injection frequency* is 24, a change is injected every 408 minutes (or every 24 job iterations).

If you choose to collect data, make sure you enable the appropriate *Collect data for...* parameter on a computer serving in the Monitor role or serving as both Injector and Monitor.

3.40.1 Resource Objects

Active Directory domain controller.

3.40.2 Default Schedule

The default interval for this script is **Daily schedule, Every 17 minutes**.

3.40.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Raise event if job fails	
Event severity when job fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the ReplicationLatency job fails. The default is 35.
Authenticate using alternate credentials?	Select **Yes** to use an alternative username and password for creating and accessing a container to test replication latency.
Username	Specify the username of the alternative account. Use the following format: `[domain name]\[username]` Leave blank to use the AppManager agent account.
Password	Specify the password of the alternative account. Leave blank to use the AppManager agent password.
Monitor Active Directory replication latency	
Role	Select the role of the server where you ran the script: **Injector**, **Monitor**, or **Both**. The default is Both. The role you select determines whether the server injects changes, monitors for changes (and measures latency), or does both. The Injector can inject changes to domain, configuration, and application partitions. If you select Injector or Monitor, you should at minimum run the job on one server acting as an Injector and a second server acting as a Monitor. If you select Both, run the job on a minimum of two servers. Run this script on multiple servers to properly monitor replication latency.
Change injection frequency	Enter a value, from 1 to 360, to determine how frequently changes are injected to test replication latency, the number of monitoring intervals between injections. The value you enter is a divisor of the interval you selected on the **Schedule** tab. For example, the default schedule for this script is Every 17 minutes (Daily schedule). With this schedule, if you enter 24 for this parameter, a change is injected every 408 minutes. The default is one change for every 24 monitoring intervals. **NOTE:** This parameter is only applicable when you select **Injector** or **Both** for the *Role* parameter.
Monitor changes from servers that are	Select the type of servers to monitor for changes: **Intersite**, **Intrasite**, or **Both**. The default is Both.
Partitions	
Change/monitor domain partition?	Select **Yes** to monitor the domain partition. The default is Yes.
Change/monitor configuration partition?	Select **Yes** to monitor the configuration partition. The default is unselected.
Change/monitor application partitions?	Select **Yes** to monitor application partitions. The default is Yes.
Monitor global catalog partitions?	Select **Yes** to monitor global catalog partitions. The default is Yes.

Parameter	How to Set It

Path to container relative to partition root	Specify any location where the container should be created. By default, the container is created in the root of the partition.
	
	For example, say the domain of the domain controller is `company.local`. If you set this parameter to `CN=AppManager` and enabled monitoring of domain and configuration partitions, the domain partition path would be:
	
	`CN=AppManager,DC=company,DC=local`
	
	and the configuration partition path would be:
	
	`CN=AppManager,CN=configuration,DC=company,DC=local`

Container name	Supply a name for a container that will be created in each of the partitions you selected for monitoring above. **NOTE:** You can specify a parent container, however you must first create that parent container with the appropriate security rights to allow creation of sub-objects using the credentials of the AppManager agent (by default) or the credentials you specified for the *Username* and *Password* parameters. The default container name is `AMReplicationLatencyObjects`.
Event Notification	
Raise event if latency threshold exceeded?	Select **Yes** to raise an event if the amount of intersite replication latency exceeds the threshold you set. The default is Yes.
Threshold – Maximum intersite latency	Specify the maximum amount of intersite replication latency that can be measured before an event is raised. The default is 540 minutes.
Threshold – Maximum intrasite latency	Specify the maximum amount of intrasite replication latency that can be measured before an event is raised. The default is 15 minutes.
Event severity when latency exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which intersite or intrasite latency exceeds the thresholds you set. The default is 10.
Raise event if time skew detected?	Select **Yes** to raise an event if the creation time of an object used for replication latency monitoring appears to be earlier than the time of the corresponding monitoring job. The default is Yes. **NOTE:** If you notice this event, verify that the report servers are synchronized to a common time source.
Event severity when time skew detected	Set the severity level, from 1 to 40, to indicate the importance of an event in which object creation time is out of sync with the monitoring job.The default is 10.
Raise event if object not updated within threshold time?	Select **Yes** to raise an event if an object is not updated within the threshold interval, which indicates that replication is not occurring. The default is Yes. **NOTE:** If you stop a server from injecting changes, delete the replication objects that represent it.
Threshold – Maximum time for object to be updated	Specify the maximum amount of time that can be taken for an object update to be completed before an event is raised. The default is 24 hours.
Event severity when object not updated within threshold time	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the time it takes to update an object exceeds the threshold. The default is 10.
Data Collection	

Parameter	How to Set It
Collect data for replication latency?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the replication latency in minutes. The default is unselected. If enabled, data streams are generated indicating the latency of the injected objects for all of the selected partitions to be monitored. **NOTE:** This parameter is only valid if you selected **Monitor** or **Both** for the *Role* parameter.
Collect data for lost data due to latency?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the number of lost changes. The default is unselected.

3.40.4 Examples of How this Script Is Used: Example 1

You have an Active Directory forest named `company.local`. It contains the server `cdc1.company.local` (the primary domain controller and global catalog server) and `cdc2.company.local` (the secondary domain controller). This forest also contains a child domain named `sales.company.local`, which has the domain controllers `scdc1.sales.company.local` and `scdc2.sales.company.local`.

To use the ReplicationLatency script to verify that replication is occurring among all the domain controllers (DCs) in this forest, you could run it on all of the DCs listed above, designating each one as "Both" Injector and Monitor for the *Role* parameter. You could set the schedule and the *Change injection frequency* parameter so that Active Directory data would be injected at each monitoring interval into each of the partition types selected.

Acting as the Injector, each DC creates a lightweight replication object, a contact object, in each selected, writeable partition. The replication object is created in the container specified by the *Container name* and *Path to container relative to partition root* parameters.

If the container for the replication objects does not exist on the local partition, the DC attempts to create the container on a DC that hosts a writeable copy of the partition. The replication object is not created locally until the container is replicated to the local partition.

At every injection interval, the Injector changes the "`description`" property of the replication object. The timestamp of the change on the Injector (Injection time) is stored in the `description` property. Active Directory replication propagates the change to DCs that host a copy of the partition.

Acting as the Monitor, the DC checks the local container specified by the *Container name* and *Path to container relative to partition root* parameters for replication objects, created and changed by each Injector. As the Monitor, it computes the latency by measuring the difference between the Arrival time (the "`whenChanged`" property) and the Injection time for each replication object.

3.40.5 Examples of How this Script Is Used: Example 2

Instead of running the ReplicationLatency script with the default setting, which places target servers in the roles of both Injector and Monitor, you could run the script on pairs of Active Directory servers. You could run it on the domain controllers `scdc1.sales.company.local` and `scdc2.sales.company.local`, designating one DC in each pair as an Injector and the other as a Monitor.

You would then enable data collection on the Monitor in each pair to measure replication latency. You would need to do the same thing for the pair `cdc1.company.local` and `cdc2.company.local`.

3.40.6 Examples of How this Script Is Used: Example 3

Extending the example introduced in "Examples of How this Script Is Used: Example 1" on page 172 to a very large Active Directory topology, the ReplicationLatency script could be used to selectively inject changes at a few key sites, while measuring changes at all the remote sites.

Suppose there are two main company sites, Corporate and Sales, where Help Desk personnel routinely handle user account and password resets. In addition, there are several thousand branch office sites, parts of a department store chain. A single DC from the Corporate site and one from the Sales site would act as both Injector and Monitor. Then a single DC from each of the branch office sites would run as a Monitor. This configuration would ensure that replication latency remained below the threshold you specified and would also cover the entire Active Directory topology, while minimizing the number of event notifications and the amount of collected data.

To isolate replication latency monitoring to intersite replication, you can deploy the ReplicationLatency script to a bridgehead server at each Injector and Monitor site.

3.41 ReplQueueLen

Use this Knowledge Script to monitor the queue length for unprocessed Active Directory replication synchronization requests. This script helps you to determine if replication synchronization requests are processed in a timely manner. In addition, this script raises an event if the unprocessed replication request queue length exceeds the threshold you set.

Replication queue length is a corollary indicator that replication is falling behind. It is standard to see one queue entry per partition. If this standard is exceeded, you should find out why replication is falling behind. Common causes include:

- The replication interval is too slow.
- A WAN link is down.
- A bridge is down (indicating a bridgehead server problem).

It is common for a bridgehead server to have many replication partners.

TIP: When setting a threshold value for the Maximum unprocessed requests in the queue parameter, try counting the number of partitions you have, add 2 (one for the schema partition and one for the configuration partition), then double the number and use the result as your threshold value.

This script gathers the following Windows performance counter values for use in data collection and threshold monitoring:

Performance Objects	Counter
NTDS	DRA Pending Replication Synchronizations
DirectoryServices	

3.41.1 Resource Objects

Active Directory domain controller

3.41.2 Default Schedule

The default interval for this script is **Every hour**.

3.41.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Raise event if job fails	

Parameter	How to Set It
Event severity when job fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the ReplQueueLen job fails. The default is 35.
Monitor replication synchronization request queue	
Event Notification	
Raise event if queue length exceeds threshold?	Select **Yes** to raise an event if the length of the replication queue exceeds the threshold you set. The default is Yes.
Threshold – Maximum unprocessed requests in queue	Specify the maximum number of replication synchronization requests that can be pending in the queue before an event is raised. The default is 12 queued requests.
Event severity when queue length exceeds threshold	Set the severity level, from 1 to 40, to indicate the importance of an event in which the length of the replication queue exceeds the threshold. The default is 20.
Data Collection	
Collect data for replication request queue length?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the number of pending synchronization requests. The default is unselected.

3.42 ReplSysVol

Use this Knowledge Script to monitor SysVol folder replication. This script raises event if a stale Active Directory replication is found.

Each time this script runs, it creates a text file under the SysVol directory on the target computer. It changes the file contents at consecutive job iterations and checks whether the changes are successfully replicated on replication partners. If the changes are not replicated successfully, the file content on the replication partners is considered stale.

This script can also validate the file size and the file content for all files under the SysVol folder on the replication partners. If you enable the *Discover all files that do not match file content?* parameter, all files are validated for size and content.

NOTE: Validating file contents can significantly increase network traffic volume. The *Perform file content validation?* parameter is disabled by default. To perform this validation, this script first does some checking, and if the file sizes of the files being compared match, which is expected when the File Replication Service (FRS) replication is occurring normally, the files are read in entirety to generate a cyclic redundancy check (CRC). Assuming FRS replication is occurring and all files are in sync, significant network traffic will probably be generated.

In some cases, the impact will be minor; the total SysVol file size for a given domain may not be very large, your network may be configured such that it can easily handle the extra traffic, or you may have set the Site option parameter to Intrasite, which disables off-site network traffic for this job. In all cases, however, you should carefully assess the likely network traffic cost of enabling file content validation before enabling this option in a production environment.

3.42.1 Resource Objects

Active Directory domain controller

3.42.2 Default Schedule

The default interval for this script is **Every 30 minutes**.

3.42.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Raise event if job fails	
Event severity when job fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the ReplSysVol job fails. The default is 35.
Monitor SysVol replication	
Site option	Select the type of replication monitoring you want the script to perform: **Intrasite**, **Intersite**, or **Both**. The default is Both.
File comparison and validation	

Parameter	How to Set It
Compare files on replication partners?	Select **Yes** to compare SysVol folders. If enabled, returns the number and names of files that are not present on the replication partners. The default is unselected.
Perform file size comparison?	Select **Yes** to compare the SysVol file sizes on the monitored computers. If enabled, returns the number and names of files whose size is not consistent on the replication partners. The default is unselected.
Perform file content validation?	Select **Yes** to compare the contents of monitored SysVol folders. If enabled, returns the number and names of files whose content is not consistent on the replication partners. The default is unselected. **Warning** Enabling this option can significantly increase network traffic in the monitored domains. See the Warning in the Knowledge Script description.
Discover all files that do not match file content?	Select **Yes** to perform validation of file size and content for all SysVol files on the replication partners. The default is unselected.
Event Notification	
Raise event if stale replication found?	Select **Yes** to raise an event if replication fails and the file contents are stale. The default is Yes.
Event severity when replication fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which replication fails and the file contents are stale. The default is 5.
Data Collection	
Collect data for SysVol replication status?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns: • 1 – SysVol replication status is up, or • 0 – SysVol replication status is down The default is unselected.

3.43 ResponseTime

Use this Knowledge Script to monitor the time it takes for the target computer to connect to and read the properties of a specific object on an Active Directory domain controller. This script raises an event if the connection or read time exceeds the threshold you set.

Increases in response time may indicate problems in Active Directory configuration.

TIP: Review response-time charts regularly to determine whether response time is trending as expected. Failure to monitor response time can lead to a wide range of problems, including very slow login times and Exchange timeouts.

3.43.1 Resource Objects

Active Directory domain controller

3.43.2 Default Schedule

The default interval for this script is **Every 5 minutes**.

3.43.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Raise event if job fails	
Event severity when job fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the ResponseTime job fails. The default is 35.
Monitor connection and read response times	
LDAP path to object on target domain controller	Enter the LDAP (Lightweight Directory Access Protocol) path to an object on the target Active Directory domain controller. The default is `LDAP://server.netiq.com/RootDSE`.
Object property to read	Specify a property of the above object that you want Active Directory to read. Valid properties depend on the object you are requesting. The default is `serverName`.
Event Notification	
Raise event if response time exceeds threshold?	Select **Yes** to raise an event if response time exceeds the threshold you set. The default is Yes.
Threshold – Maximum connection time	Specify the maximum number of milliseconds allowed to connect to the Active Directory domain controller before an event is raised. The default is 1000 milliseconds.
Threshold – Maximum read time	Specify the maximum number of milliseconds allowed to read the property value before an event is raised. The default is 1000 milliseconds.

Parameter	How to Set It
Event severity when response time exceeds threshold	Set the severity level, from 1 to 40, to indicate the importance of an event in which response time exceeds the threshold. The default is 15.
Data Collection	
Collect data for response times?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns two data streams, one for the connection time and one for the read time. The default is unselected.

3.44 SearchStat

Use this Knowledge Script to monitor the number of Active Directory search operations per second. If the search rate exceeds the threshold you set, an event is raised.

If you use this script to collect data, use the *Data collection mode* parameter to choose what is included in the data stream and data detail message:

- One data stream that records the total search rate. The data detail message describes the percentage of Active Directory searches that are being performed by various services, such as DRA, KCC, LDAP, LSA, NSPI, SAM, XDS, NTDSAPI.
- One data stream that records the total search rate, but without the detail message breakdown.
- Data streams that track the total number of searches per second and the number of searches per second for various services independently, such as data streams for the search rate of DRA, KCC, LDAP, LSA, NSPI, SAM, XDS, and NTDSAPI.

If you collect data, keep in mind that the more data streams and detail you collect, the greater the impact on your database management system and overall performance. For example, if you choose the third data collection option, consider adjusting your archive policies or increase the frequency at which you check the size of Data tables in the AppManager repository.

This script gathers the following Windows performance counter values for use in data collection and threshold monitoring:

Performance Objects	Counters
NTDS DirectoryServices	For monitoring, only the following counter is used to determine whether the threshold has been crossed and an event should be raised: • DS Directory Searches/sec If data collection is enabled and data collection mode 1 or 3 is specified, values for the following counters are included in the data detail message: • DS % Searches from DRA • DS % Searches from KCC • DS % Searches from LDAP • DS % Searches from LSA • DS % Searches from NSPI • DS % Searches from SAM • DS % Searches from XDS • DS % Searches from NTDSAPI (Windows Server 2003 and Windows Server 2008)

3.44.1 Resource Objects

Active Directory domain controller

3.44.2 Default Schedule

The default interval for this script is **Every 30 minutes**.

3.44.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Raise event if job fails	
Event severity when job fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the SearchStat job fails. The default is 35.
Monitor rate of search operations	
Event Notification	
Raise event if search rate exceeds threshold?	Select **Yes** to raise an event if the number of search operations per second exceeds the threshold you set. The default is Yes.
Threshold – Maximum search rate	Specify the maximum number of Active Directory search operations allowed per second before an event is raised. The default is 1 search per second.
Event severity when search rate exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of search operations per second exceeds the threshold. The default is 20.
Data Collection	
Collect data for search rate?	Select **Yes** to collect data for charts and reports. If you enable data collection, specify the data collection mode to use in the *Data collection mode* parameter. The default is unselected.
Data collection mode	Specify the type of data you want to collect. The following entries are valid: • 1 – one data stream that records the total search rate (searches/second). The data detail message describes the percentage of Active Directory search operations that are performed by various services. • 2 – one data stream that records the total search rate without any detail message. • 3 – several data streams: total search rate for all Active Directory services, and one data stream for each separate service. The default is 1 (one data stream and detail message).

3.45 ServerHealth

Use this Knowledge Script to monitor the health of an Active Directory domain controller.

By default, this script checks to see if essential Active Directory services are installed and/or running. You can also monitor the optional DNS server service, and you can disable monitoring of any essential service.

This script using the WMI (Windows Management Instrumentation) replication provider service to check for error conditions related to replication, and uses the WMI Trustmon provider service to verify trust relationships between domains. The WMI Trustmon provider service was introduced in Windows Server 2003 and is not available in earlier versions of Windows. This script raises an event if the WMI Trustmon provider service is not installed. The event provides information on how to install the WMI provider.

You can configure events of varying severity levels to identify critical conditions, error conditions, warning conditions, and informational conditions. You can also set thresholds for the maximum time that can elapse between successful replications and the maximum consecutive number of synchronization failures.

3.45.1 Resource Objects

Active Directory domain controller

3.45.2 Default Schedule

The default interval for this script is **Every 10 minutes**.

3.45.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Raise event if job fails	
Event severity when job fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the ServerHealth job fails. The default is 35.
Monitor essential services?	
Services	
DNS Client	Select **Yes** to monitor the health of the DNS Client service. The default is Yes.
DNS Server	Select **Yes** to monitor the health of the DNS Server service. The default is Yes.
Event Log	Select **Yes** to monitor the health of the Event Log service. The default is Yes.
File Replication Service	Select **Yes** to monitor the health of the File Replication Service (FRS) service. The default is Yes.
Intersite Messaging	Select **Yes** to monitor the health of the Intersite Messaging service. The default is Yes.
Kerberos Key Distribution Center	Select **Yes** to monitor the health of the Kerberos Key Distribution Center (KDC) service. The default is Yes.

Parameter	How to Set It
Net Logon	Select **Yes** to monitor the health of the Net Logon service. The default is Yes.
Server	Select **Yes** to monitor the health of the Server service. The default is Yes.
Windows Management Instrumentation (for monitoring)	Select **Yes** to monitor the health of the Windows Management Instrumentation (WMI) service. The default is Yes.
Windows Time	Select **Yes** to monitor the health of the Windows Time service. The default is Yes.
Workstation	Select **Yes** to monitor the health of the Workstation service. The default is Yes.
Event Notification	
Raise event if service is installed but not running?	Select **Yes** to enable events if the monitored service is installed but has not been started. The default is Yes.
Event severity when service not running	Set the severity level, from 1 to 40, to indicate the importance of an event in which the monitored service is installed but has not been started. The default is 10.
Monitor Active Directory replication?	
Event Notification	
Raise event if WMI replication provider not installed?	Select **Yes** to raise an event if the WMI Active Directory replication provider service is not found. The default is Yes.
Event severity when WMI replication provider not installed	Set the severity level, from 1 to 40, to indicate the importance of an event in which the WMI Active Directory replication provider service is not found. The default is 30.
Raise event if replication is not healthy?	Select **Yes** to raise an event if replication error conditions are detected. The default is Yes.
Error threshold – Maximum time since last successful replication	Specify the maximum number of days that can elapse since the last successful replication occurred. If the threshold is exceeded, an event is raised. The default is 3 days.
Warning threshold – Maximum consecutive sync failures	Specify the maximum number of synchronization failures that can occur before an event is raised. The default is 3 failures.
Event severity for critical error event	Set the severity level, from 1 to 40, to indicate the importance of an event in which a condition is detected that constitutes a critical error. The default is 5. An event is always raised if a critical error is detected.
Event severity for Error event	Set the severity level, from 1 to 40, to indicate the importance of an event in which a medium-severity event condition is detected. The default is 10.
Event severity for Warning event	Set the severity level, from 1 to 40, to indicate the importance of an event in which a high-severity event condition is detected. The default is 20.
Raise event if replication is healthy?	Select **Yes** to raise an event if no replication error conditions are detected. The default is unselected.
Event severity for Information event	Set the severity level, from 1 to 40, to indicate the importance of an event in which a low-severity event condition is detected. The default is 30.
Monitor trusts?	

Parameter	How to Set It
Trust verification level	Select the verification level to use for trust verification: **SC_QUERY**, **Password**, or **SC_RESET**. The default is Password. In order for the parameter setting to take effect, restart the WMI service after you run the job for the first time. **Important** Restarting the WMI service can cause Knowledge Script jobs to fail and raise events. Stop any running Knowledge Script jobs before restarting the WMI service.
Event Notification	
Raise event if WMI Trustmon provider is not installed?	Select **Yes** to raise an event if the WMI Trustmon provider service cannot be found. The default is Yes.
Event severity when WMI Trustmon provider not installed	Set the severity level, from 1 to 40, to indicate the importance of an event in which the WMI Trustmon provider service cannot be found. The default is 30.
Raise event if Windows trust in error?	Select **Yes** to raise an event if an error is found in the Windows trust. The default is Yes.
Event severity when Windows trust in error	Set the severity level, from 1 to 40, to indicate the importance of an event in which an error is found in the Windows trust. The default is 10.
Raise event if trusts are found that cannot be monitored?	Select **Yes** to raise an event if trusts are found that cannot be monitored. **NOTE:** The WMI Trustmon provider (installed by default on Windows Server 2003) can only monitor Windows trusts that are inbound-only. Non-Windows trusts cannot be monitored with this script. The default is unselected.
Event severity when trusts not monitored	Set the severity level, from 1 to 40, to indicate the importance of an event in which trusts are found that cannot be monitored. The default is 25.

3.46 SyncRequest

Use this Knowledge Script to monitor the number of failed Active Directory replication synchronization requests from the target server. This script raises an event if the number of synchronization requests that fail per second exceeds the threshold you set.

This script gathers the following Windows performance counter values for use in data collection and threshold monitoring:

Performance Objects	Counters
NTDS DirectoryServices	The following counters are used to determine the number of failed sync requests: • DRA Sync Requests Made • DRA Sync Requests Successful

The number of failed sync requests is calculated using the following formula:

```
DRA Sync Requests Made – DRA Sync Requests Successful
```

The number of failed sync requests for the current iteration is computed by subtracting the number of failed sync requests at the previous iteration. The percentage of failed synchronization requests since the past iteration is computed and used for threshold comparison.

3.46.1 Resource Objects

Active Directory domain controller

3.46.2 Default Schedule

The default interval for this script is **Every hour**.

3.46.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Raise event if job fails	
Event severity when job fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the SyncRequest job fails. The default is 35.
Monitor synchronization failure rate?	
Event Notification	
Raise event if sync failure rate exceeds threshold?	Select **Yes** to raise an event if the sync failure rate exceeds the threshold you set. The default is Yes.

Parameter	How to Set It
Threshold – Maximum sync failure rate	Specify the maximum percentage of synchronization requests that can have failed since the last script iteration before an event is raised. The default is 90%.
Event severity when sync failure rate exceeds threshold	Set the severity level, from 1 to 40, to indicate the importance of an event in which the sync failure rate exceeds the threshold. The default is 20.
Data Collection	
Collect data for synchronization failures?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns: • The synchronization failure rate • The total number of synchronization requests made • The number of successful synchronization requests The default is unselected.

3.47 WriteStat

Use this Knowledge Script to monitor the number of Active Directory write operations per second. This script raises an event if the write rate exceeds the threshold you set.

If you use this script to collect data, you can choose what is included in the data stream and data detail message:

- One data stream that records the total write rate. The data detail message describes the percentage of Active Directory write operations that are being performed by various services, such as DRA, KCC, LDAP, LSA, NSPI, SAM, XDS, and NTDSAPI.
- One data stream that records the total write rate, but without the detail message breakdown.
- Data streams that track the total number of write operations per second and the number of writes per second for various services independently, such as DRA, KCC, LDAP, LSA, NSPI, SAM, XDS, and NTDSAPI.

If you collect data, keep in mind that the more data streams and details you collect, the greater the impact on your database management system and overall performance. For example, if you choose the third data collection option, consider adjusting your archive policies or increase the frequency at which you check the size of Data tables in the AppManager repository.

This script gathers the following Windows performance counter values for use in data collection and threshold monitoring:

Performance Objects	Counters
NTDS DirectoryServices	For monitoring, only the following counter is used to determine whether the threshold has been crossed and an event should be raised: • DS Directory Writes/sec If data collection is enabled and data collection mode 1 or 3 is specified, values for the following counters are included in the data detail message: • DS % Writes from DRA • DS % Writes from KCC • DS % Writes from LDAP • DS % Writes from LSA • DS % Writes from NSPI • DS % Writes from SAM • DS % Writes from XDS • DS % Writes from NTDSAPI (Windows Server 2003 and Windows Server 2008)

3.47.1 Resource Objects

Active Directory domain controller

3.47.2 Default Schedule

The default interval for this script is **Every 30 minutes**.

3.47.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Raise event if job fails	
Event severity when job fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the WriteStat job fails. The default is 35.
Raise event if write rate exceeds threshold?	Select **Yes** to raise an event if the number of write operations per second exceeds the threshold you set. The default is Yes.
Event Notification	
Threshold – Maximum write rate	Specify the maximum number of Active Directory write operations allowed per second before an event is raised. The default is 1 write operation per second.
Event severity when write rate exceeds threshold	Set the severity level, from 1 to 40, to indicate the importance of an event in which the number of write operations per second exceeds the threshold. The default is 20.
Data Collection	
Collect data for write rate?	Select **Yes** to collect data for charts and reports. If enabled, specify the data collection mode to use in the *Data collection mode* parameter. The default is unselected.
Data collection mode	Specify the type of data you want to collect. The following entries are valid: • 1 – one data stream that records the total search rate (searches/second). The data detail message describes the percentage of Active Directory search operations that are performed by various services. • 2 – one data stream that records the total search rate without any detail message. • 3 – several data streams: total search rate for all Active Directory services, and one data stream for each separate service. The default is 1 (one data stream and detail message).

3.48 AD Knowledge Script Groups

The following Knowledge Script Groups (KSGs) are installed as part of the installation of AppManager for Active Directory. Like other Knowledge Scripts for monitoring Active Directory, they are located on the AD Knowledge Script tab. However, they are also accessible from the RECOMMENDED Knowledge Script tab.

3.48.1 Tips for Using Knowledge Script Groups

The AD KSGs contain a recommended subset of Active Directory scripts that represent a "best practices" usage of AppManager for monitoring Active Directory in your organization. These KSGs can be used with AppManager monitoring policies. A monitoring policy, which you can use to efficiently and consistently monitor all of the resources in your environment, uses a set of pre-configured Knowledge Scripts to automatically monitor resources as they appear in the TreeView. For more information, see the topic titled "About policy-based monitoring" in the AppManager Help.

Generally, each of the KSGs is intended to be used only in the role that is specified as part of the description of the group, with the exception of the AD KSG. Unlike the others, the AD KSG leverages the Knowledge Script job delegation feature included with AppManager for Active Directory 6.2.

Whereas the recommended KSGs are designed to be deployed only on the Domain Controllers listed in the description of each group, the AD KSG executes only on role-holding Domain Controllers. The AD KSG should be used as an alternative to all the others; that is, you should either use the AD KSG or each of the separate KSGs as designated.

KSGs are composed of selected scripts from the regular Knowledge Script tabs. When you modify a script, keep in mind that the script that belongs to a KSG is a different copy of the actual script you access from the **AD** tab. The changes you make are not reflected in the script that is part of the KSG.

In some cases, default script parameter settings are different when the script is deployed as part of a KSG, as opposed to when it is deployed alone. The default settings of a script within a group depend on its monitoring purpose within the larger group, and on the intended monitoring scope of that group, such as a single domain or an entire forest.

If you modify or remove a script associated with one of these RECOMMENDED KSGs and want to restore it to its original form, you can either reinstall AppManager for Active Directory on the repository computer or check in the appropriate script from the `qdb\kp\ad\<Knowledge Script Group name>` directory.

3.49 AD

Deploy this Knowledge Script Group (KSG) to all domain controllers you want to monitor. This comprehensive KSG has the job delegation feature enabled for Knowledge Scripts that support this feature. If you use this KSG, avoid using the other recommended KSGs that do not employ the job delegation feature. For more information about job delegation, see "AD Knowledge Script Job Delegation" on page 90.

The AD KSG contains the following scripts:

Knowledge Script	Default Settings Changed for Use in Knowledge Script Group
Authentications	• Collect data for Kerberos authentications? (enabled) • Collect data for NTLM authentications? (enabled)
BridgeheadChange	• Enable job delegation? (enabled)
ClientSessions	• Collect data for number of client sessions? (enabled) • Threshold – Maximum number of client sessions (250)
DatabaseSize	• Collect data for database disk space usage? (enabled) Advanced Option (**Advanced** Properties tab): • Collect data every 96 job iterations. Calculate Average.
DCAdvertised	None.
DCHealthMonitor	• Collect data for DC health? (enabled) Advanced Option (**Advanced** Properties tab): • Collect data every 12 job iterations. Calculate Average.
DCInSiteConnectivity	• Enable job delegation? (enabled)
DomainConnectivity	• Enable job delegation? (enabled)
EnumerateSites	• Enable job delegation? (enabled)
EventLog	• Filter – Source (`NTDS KCC`)
EventLog (NetLogon)	None.
EventLog (W32Time)	None.
FSMOChange	• Enable job delegation? (enabled)
FSMOHealth	• Enable job delegation? (enabled)
FSMOPlacement	• Enable job delegation? (enabled)
GlobalCatalogChange	• Enable job delegation? (enabled)
GlobalCatalogHealth	• Enable job delegation? (enabled) • Collect data for global catalog status? (enabled)
KCCConnections	None.
KCCDisabled	Enable job delegation? (enabled)
KDCRequests	None.

Knowledge Script	Default Settings Changed for Use in Knowledge Script Group
NumberOfObjects	• Enable job delegation? (enabled) • Object class to check (* for all classes) (*) • Raise event if number of objects exceeds threshold? (enabled) • Collect data for number of objects? (enabled) • Number of objects to return (0 for all objects) (1)
NumberOfUsersLocked	• Enable job delegation? (enabled) • Collect data for number of locked user accounts? (enabled)
ReplEventLog	None.
ReplSysVol	None.
ResponseTime	• Collect data for response times? (enabled) Advanced Option (**Advanced** Properties tab): • Collect data every 12 job iterations. Calculate Average.
ServerHealth	None.
SyncRequest	None.

3.50 AD (all DCs)

Deploy this Knowledge Script Group (KSG) to all domain controllers you want to monitor. This KSG contains the following scripts:

Knowledge Script	Default Settings Changed for Use in Knowledge Script Group
Authentications	• Collect data for Kerberos authentications? (enabled) • Collect data for NTLM authentications? (enabled
ClientSessions	• Collect data for number of client sessions? (enabled) • Threshold – Maximum number of client sessions (250)
DatabaseSize	• Collect data for database disk space usage? (enabled) Advanced Option (**Advanced** Properties tab): • Collect data every 96 job iterations. Calculate Average.
DCAdvertised	None.
DCHealthMonitor	• Collect data for DC health? (enabled) Advanced Option (**Advanced** Properties tab): • Collect data every 12 job iterations. Calculate Average.
DCInSiteConnectivity	None.
EventLog (NetLogon)	None.
EventLog (W32Time)	None.
EventLog	Filter – Source (`NTDS KCC`)
KCCConnections	None.
KDCRequests	None.
ReplEventLog	None.
ReplSysVol	None.
ResponseTime	• Collect data for response times? (enabled) Advanced Option (**Advanced** Properties tab): • Collect data every 12 job iterations. Calculate Average.
ServerHealth	None.
SyncRequest	None.

3.51 AD (one DC per domain)

Deploy this Knowledge Script Group (KSG) to a single domain controller per domain. This KSG contains the following scripts:

Knowledge Script	Default Settings Changed for Use in Knowledge Script Group
DomainConnectivity	None.
FSMOChange	None.
FSMOHealth	None.
FSMOPlacement	None.
NumberOfObjects	• Object class to check (* for all classes) (*) • Raise event if number of objects exceeds threshold? (enabled) • Collect data for number of objects? (enabled) • Number of objects to return (0 for all objects) (1)
NumberOfUsersLocked	• Collect data for number of locked user accounts? (enabled)

3.52 AD (one DC per forest)

Deploy this Knowledge Script Group (KSG) to a single domain controller per forest. This KSG contains the following scripts:

Knowledge Script	Default Settings Changed for Use in Knowledge Script Group
BridgeheadChange	None.
EnumerateSites	None.
GlobalCatalogChange	None.

3.53 AD (one DC per site)

Deploy this Knowledge Script Group (KSG) to a single domain controller per site. This KSG contains the following scripts:

Knowledge Script	Default Settings Changed for Use in Knowledge Script Group
GlobalCatalogHealth	Collect data for global catalog status? (enabled)
KCCDisabled	None.

4 AD-RT Knowledge Scripts

The AD-RT category provides a set of Knowledge Scripts for monitoring Active Directory response time with AppManager.

From within the AD-RT view of the Operator Console, you can select a Knowledge Script or report by clicking the **AD-RT** tab of the Knowledge Script pane.

If you choose to collect data, each Knowledge Script generates the following data streams:

- **Availability**

  This data stream returns one of two values (depending on the data stream format you selected):

  - 1 or 100 = transaction was successful
  - 0 = transaction was not successful

  The Availability data point is an indication of whether the test succeeded or failed. If, for example, a connection to the Active Directory Server was established but the test transaction failed to complete, the Availability data point will be 0 (not available, or not successful).

- **Response time**

  The information returned by this data stream is also saved with the data point, and can be viewed by double-clicking the data point in the Graph Pane or Chart Console.

  A Response Time data stream is only generated if the entire transaction is successful.

- **Response time breakdown**

  For the GetObject Knowledge Script, you can enable data collection for up to 3 response-time breakdown data streams. These are individual data points for the different parts of the Knowledge Script transaction that can be timed.

Most AD-RT Knowledge Scripts require you to enter username and password information to log into the network domain and separate account and password information to run the application. An exception is the QueryService Knowledge Script, which uses Windows NT authentication (or "integrated security") and therefore uses the same username and password information to run the application and log into the domain.

Following are the Knowledge Scripts in the AD-RT category:

Knowledge Script	What It Does
CheckDomainController	Checks Active Directory domain controller connectivity.
DNSNameLookup	Checks ability of a DNS server to resolve a particular hostname.

Knowledge Script	What It Does
DNSSpecificServerNameLookup	Checks ability of a DNS server to resolve a particular hostname on a specific server.
GetObject	Retrieves content from the Active Directory server.
QueryService	Monitors the availability and status of a service on a computer in the Active Directory domain.
Report_AD-RT	Generates a report on availability and response time.
Report_AD-RT_DNS	Generates a report on DNS availability and response time.

4.1 CheckDomainController

Use this Knowledge Script to monitor Active Directory Domain Controllers (DCs). The Knowledge Script checks to see if the DC is running; if it is, the Knowledge Script measures response time information for a performance check.

If you choose to collect data, this Knowledge Script generates the following data streams:

- **Availability**–Returns one of the following values:
  - 1 or 100 – the transaction was successful
  - 0 – the transaction was not successful

  The Availability data point is an indication of whether the test succeeded or failed.
- **Response time**

  The information returned by this data stream is also saved with the data point, and can be viewed by double-clicking the data point in the Graph Pane or Chart Console.

  A Response Time data stream is only generated if the entire transaction is successful.

You can select where some of the possible events are displayed in the Operator Console TreeView or Control Center Console Server view. This event proxying feature is useful in Control Center Service Map views. It is not supported for jobs that are started in the Operator Web Console. See the description of the **Event on** parameter, below.

An event is raised whenever one of the following occurs:

- A threshold that you have specified as an event parameter is exceeded.
- The AD-RT engine can't be initialized. An initialization error is generated, but an Availability or Response Time data stream is not generated.
- The transaction doesn't complete successfully. A transaction error is generated. Only an Availability data stream is generated, with a value of 0.

Enter the name of the Domain Controller as the server when using this Knowledge Script in a service connection.

4.1.1 Resource Objects

Active Directory response time clients (AD-RT).

4.1.2 Default Schedule

The default interval for this Knowledge Script is **Every 15 minutes**.

4.1.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Availability	
Collect data for availability?	Select the **Yes** check box to collect data for graphs and reports. If enabled, returns: • 1 or 100 – Transaction completed successfully • 0 – Transaction did not complete successfully By default, data is collected.
Data stream format	Select the data stream format for the Availability data stream. Previous versions of AppManager ResponseTime used a 0 (“not available”) or 1 (“available”) format to indicate availability. You now have the option to use a 0 (“not available”) or 100 (“available”) format. The default value is 0-100.
Raise event if transaction fails?	Select the **Yes** check box to raise an event when the server cannot be contacted. By default, events are enabled.
Event severity when transaction fails	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 5. If you disable availability failure events, this value is ignored.
Response Time	
Collect data for response time?	Select the **Yes** check box to collect response time data for graphs and reports. By default, data is collected.
Threshold – Maximum response time (seconds)	Specify the maximum number of seconds that the transaction can take before an event is raised. The event message contains a breakdown of the total response time. The default is 5 seconds.
Raise event if threshold is exceeded?	Select the **Yes** check box to raise an event when the response time exceeds the threshold. By default, events are raised.
Event severity when threshold is exceeded	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 15.
Domain controller name	Enter the name of the Domain Controller that should receive the response time test flows. If you’re setting the **Event on** parameter (see below), the **Domain Controller name** parameter lets you select the server where the event will appear in your console. Enter the name of the server, or click the browse button ([**...**]) to select from a list of available servers. The Domain Controller you select must already be in the TreeView.
Event on	Select the TreeView location where events should be displayed. Select either: • **Agent** (the client computer in the response-time tests). This is the default. • **Server** (the Domain Controller being tested) • **Both.** The event will be shown in two locations in the TreeView. **Notes** This setting does not apply to events related to the Knowledge Script itself, such as Knowledge Script failure or initialization problems. Such events are always displayed on the computer where the job ran. You must select `Agent` when starting jobs in the Operator Web Console. If you select `Server`, no events are generated. If you select `Both`, an event is only shown on the agent.
Logon	

Description	How to Set It
Username	Enter the username to use to log onto the DC.
Password	Enter the password associated with this user.
Domain	Enter the domain name associated with this user.

4.2 DNSNameLookup

Use this Knowledge Script to check the ability of your Domain Name System (DNS) server to resolve a particular hostname. If the hostname is not found, the Knowledge Script generates a success event and continues to run (to indicate that it was able to contact the DNS server).

NOTE: The local hosts file will never be used, even if it is enabled on the client.

If you choose to collect data, this Knowledge Script generates the following data streams:

- **Availability**

  This data stream returns one of two values (depending on the data stream format you selected):

  – 1 or 100 = transaction was successful

  – 0 = transaction was not successful

- **Response Time**

  The information returned by this data stream is also saved with the data point, and can be viewed by double-clicking the data point in the Graph Pane or Chart Console.

  A Response Time data stream is only generated if the entire transaction is successful.

If this Knowledge Script is able to connect to the specified DNS server, data streams for Availability (showing 100 for available) and response time are created, regardless of whether the hostname you supplied can be resolved or not.

An event is raised whenever one of the following occurs:

- A threshold that you have specified as an event parameter is exceeded.
- The AD-RT engine can't be initialized. An initialization error is generated, but an Availability or Response Time data stream is not generated.
- The job transaction doesn't complete successfully. A transaction error is generated. Only an Availability data stream is generated, with a value of 0.

4.2.1 Resource Objects

Active Directory response time clients (AD-RT).

4.2.2 Default Schedule

The default interval for this Knowledge Script is **Every 15 minutes**.

4.2.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Availability	
Collect data for availability?	Select the **Yes** check box to collect data for graphs and reports. If enabled, returns: • 1 or 100 – Transaction completed successfully • 0 – Transaction did not complete successfully By default, data is collected.
Data stream format	Select the data stream format for the Availability data stream. Previous versions of AppManager ResponseTime used a 0 (“not available”) or 1 (“available”) format to indicate availability. You now have the option to use a 0 (“not available”) or 100 (“available”) format. The default value is 0-100.
Raise event if transaction fails?	Select the **Yes** check box to raise an event when the server cannot be contacted. By default, events are enabled.
Event severity when transaction fails	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 5. If you disable availability failure events, this value is ignored.
Response Time	
Collect data for response time?	Select the **Yes** check box to collect response time data for graphs and reports. By default, data is collected.
Threshold – Maximum response time (seconds)	Specify the maximum number of seconds that the transaction can take before an event is raised. The event message contains a breakdown of the total response time. The default is 5 seconds.
Raise event when threshold is exceeded?	Select the **Yes** check box to raise an event when the response time exceeds the threshold. By default, events are raised.
Event severity when threshold is exceeded	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 15.
Hostname to resolve	Enter the name of the host computer to be resolved.

4.3 DNSSpecificServerNameLookup

Use this Knowledge Script to check the ability of your Domain Name System (DNS) server to resolve a particular hostname on a specific server. If the hostname is not found, the Knowledge Script generates a success event and continues to run (indicating that it was able to contact the DNS server).

The value you supply for the **Hostname to resolve** parameter must be a fully-qualified hostname, or the transaction will fail with an execution error.

NOTE: The local hosts file will never be used, even if it is enabled on the client.

If you choose to collect data, this Knowledge Script generates the following data streams:

- **Availability**

  This data stream returns one of two values (depending on the data stream format you selected):

  – 1 or 100 = transaction was successful

  – 0 = transaction was not successful

- **Response Time**

  The information returned by this data point is also saved with the data point, and can be viewed by double-clicking the data point in the Graph Pane or Chart Console.

  A Response Time data stream is only generated if the entire transaction is successful.

If this Knowledge Script is able to connect to the specified DNS server, data streams for Availability (showing 100 for available) and response time are created, regardless of whether the hostname you supplied can be resolved or not.

You can select where some of the possible events are displayed in the Operator Console TreeView or Control Center Console Server view. This event proxying feature is useful in Control Center Service Map views. It is not supported for jobs that are started in the Operator Web Console. See the description of the **Event on** parameter, below.

An event is raised whenever one of the following occurs:

- A threshold that you have specified as an event parameter is exceeded.
- The AD-RT engine can't be initialized. An initialization error is generated, but an Availability or Response Time data stream is *not* generated.
- The job transaction doesn't complete successfully. A transaction error is generated. Only an Availability data stream is generated, and the value = 0.

4.3.1 Resource Objects

The Active Directory response time clients (AD-RT).

4.3.2 Default Schedule

The default interval for this Knowledge Script is **Every 15 minutes**.

4.3.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Availability	
Collect data for availability?	Select the **Yes** check box to collect availability data for graphs and reports. By default, data is collected.
Data stream format	Select the data stream format for the Availability data stream. Previous versions of AppManager ResponseTime used a 0 (“not available”) or 1 (“available”) format to indicate availability. You now have the option to use a 0 (“not available”) or 100 (“available”) format. The default value is 0-100.
Raise event if transaction fails?	Select the **Yes** check box to raise an event when the server cannot be contacted. By default, events are enabled.
Event severity when transaction fails	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 5. If you disable availability failure events, this value is ignored.
Response Time	
Collect data for response time?	Select the **Yes** check box to collect response time data for graphs and reports. By default, data is collected.
Threshold – Maximum response time (seconds)	Specify the maximum number of seconds that the transaction can take before an event is raised. The event message contains a breakdown of the total response time. The default is 5 seconds.
Raise event when threshold is exceeded?	Select the **Yes** check box to raise an event when the response time exceeds the threshold. By default, events are raised.
Event severity when threshold is exceeded	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 15.
DNS server name	Enter the hostname of the DNS server to query, with no spaces. If you’re setting the **Event on** parameter (see below), the **DNS Server name** parameter lets you select the server where the event will appear in your console. Enter the name of the server, or click the browse button ([**...**]) to select from a list of available servers. The server you select must already be in the TreeView.
Event on	Select the TreeView location where events should be displayed. Select either: • **Agent** (the client computer in the response-time tests). This is the default. • **Server** (the DNS server being tested) • **Both.** The event will be shown in two locations in the TreeView. **Notes** This setting does not apply to events related to the Knowledge Script itself, such as Knowledge Script failure or initialization problems. Such events are always displayed on the computer where the job ran. You must select `Agent` when starting jobs in the Operator Web Console. If you select `Server`, no events are generated. If you select `Both`, an event is only shown on the agent.
Hostname to resolve	Enter the fully qualified name of the host computer to be resolved.

4.4 GetObject

Use this Knowledge Script to retrieve content from the Active Directory server. Running this Knowledge Script will indicate the response time and availability of this process. The Knowledge Script returns an error if the object path is not found.

If you choose to collect data, this Knowledge Script generates the following data streams:

- **Availability**

  This data stream returns one of two values (depending on the data stream format you selected):

  - 1 or 100 = transaction was successful
  - 0 = transaction was not successful

- **Response time**

  - **Overall response time**. The information returned by this data stream is also saved with the data point, and can be viewed by double-clicking the data point in the Graph Pane or Chart Console.
  - **Response-time Breakdown**. If enabled as separate parameters, up to 3 response-time breakdown data streams. These are individual data points for the different parts of the Knowledge Script transaction that are timed. See "Setting Parameter Values" on page 206 below for more information.

  A Response Time data stream is only generated if the entire transaction is successful.

You can select where some of the possible events are displayed in the Operator Console TreeView or Control Center Console Server view. This event proxying feature is useful in Control Center Service Map views. It is not supported for jobs that are started in the Operator Web Console. See the description of the **Event on** parameter, below.

An event is raised whenever one of the following occurs:

- A threshold that you have specified as an event parameter is exceeded.
- The AD-RT engine can't be initialized. An initialization error is generated, but an Availability or Response Time data stream is not generated.
- The job transaction doesn't complete successfully. A transaction error is generated. Only an Availability data stream is generated, with a value of 0.

4.4.1 Resource Objects

Active Directory response time clients (AD-RT).

4.4.2 Default Schedule

The default interval for this Knowledge Script is **Every 15 minutes**.

4.4.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Availability	
Collect data for availability?	Select the **Yes** check box to collect data for graphs and reports. If enabled, returns: • 1 or 100 – Transaction completed successfully • 0 – Transaction did not complete successfully By default, data is collected.
Data stream format	Select the data stream format for the Availability data stream. Previous versions of AppManager ResponseTime used a 0 (“not available”) or 1 (“available”) format to indicate availability. You now have the option to use a 0 (“not available”) or 100 (“available”) format. The default value is 0-100.
Raise event if transaction fails?	Select the **Yes** check box to raise an event when the server cannot be contacted. By default, events are enabled.
Event severity when transaction fails	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 5. If you disable availability failure events, this value is ignored.
Response Time	
Collect data for response time?	Select the **Yes** check box to collect response time data for graphs and reports. By default, data is collected.
Threshold – Maximum response time (seconds)	Specify the maximum number of seconds that the transaction can take before an event is raised. The event message contains a breakdown of the total response time. The default is 5 seconds.
Raise event if threshold is exceeded?	Select the **Yes** check box to raise an event when the response time exceeds the threshold. By default, events are raised.
Event severity when threshold is exceeded	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 15.
Response Time Breakdown	
Collect data for binding object?	Select the **Yes** check box to collect a separate response-time data stream for the time taken to bind to the specified object. By default, separate response-time data streams are not collected.
Collect data for listing containers?	Select the **Yes** check box to collect a separate response-time data stream for the time taken to list the containers in which the object is located. This data stream can only be collected if you enabled the **List container objects?** parameter (see below). By default, separate response-time data streams are not collected.
Collect data for downloading objects or containers?	Select the **Yes** check box to collect a separate response-time data stream for the time taken to download any objects or containers from the domain controller. This data stream can only be collected if you enabled the **Download container objects?** parameter (see below). By default, separate response-time data streams are not collected.

Description	How to Set It
Target computer	Enter the hostname of the domain controller, or click the browse button ([**...**]) to select from a list of available servers. The “target computer” is used to enable retrieval of data streams by AppManager Analysis Center v2.0 and higher. If specified, it will also be used in place of “Default Active Directory Server” in the data stream legend. If you’re setting the **Event on** parameter (see below), the **Target computer** parameter also determines the computer where the event will appear in your console. The computer you select must already be in the TreeView.

Object path	`ADsPath` of object to be processed. This is in the form: `<provider name>://<distinguished name>`
	
	where:
	• `<provider name>` is the name of the AD Service provider you want to use. Typical ones are LDAP and WinNT. This is case-sensitive.
	• `<distinguished name>` is a provider-specific path and name that uniquely describe the location of the resource.
	
	For LDAP, a distinguished name might be
	
	`CN=RALD01,ou=Domain Controllers,dc=netiq,dc=local`
	
	For WinNT, it might be
	
	`netiq.local/raldc01/QA`

List container objects?	Select the **Yes** check box to perform the action of listing the resources the object contains. There is a maximum of 1000 objects. You can enable the collection of response time for this action as a separate step (see above).
Download container objects?	Select the **Yes** check box to perform the action of downloading the objects. There is a maximum of 1000 objects. You can enable the collection of response time for this action as a separate step (see above). **NOTE:** If **List container objects** is disabled and **Download container objects** is disabled, *or* if the object is not a container, the system times the action of downloading information about the object itself. (You cannot enable **List container objects** and disable **Download container objects** when the object is a container.)
Maximum number of container objects	Enter a value, from 1 to 1000, that specifies the maximum number of objects in the container. The default is 1000.
Event on	Select the TreeView location where events should be displayed. Select either: • **Agent** (the client computer in the response-time tests). This is the default. • **Server** (the server being tested) • **Both**. The event will be shown in two locations in the TreeView. **Notes** This setting does not apply to events related to the Knowledge Script itself, such as Knowledge Script failure or initialization problems. Such events are always displayed on the computer where the job ran. You must select `Agent` when starting jobs in the Operator Web Console. If you select `Server`, no events are generated. If you select `Both`, an event is only shown on the agent.
Logon	
Username	Enter the username to use to log onto the Active Directory server.
Password	Enter the password associated with this user.

Description	How to Set It
Domain	Enter the domain name associated with this user.

4.5 QueryService

Use this Knowledge Script to monitor the availability and status of a service on a computer in the Active Directory domain.

If you choose to collect data, this Knowledge Script generates the following data streams:

- **Availability**

  This data stream returns one of two values (depending on the data stream format you selected):

  - 1 or 100 = transaction was successful
  - 0 = transaction was not successful

- **Response Time**

  The information returned by this data stream is also saved with the data point, and can be viewed by double-clicking the data point in the Graph Pane or Chart Console.

  A Response Time data stream is only generated if the entire transaction is successful.

You can select where some of the possible events are displayed in the Operator Console TreeView or Control Center Console Server view. This event proxying feature is useful in Control Center Service Map views. It is not supported for jobs that are started in the Operator Web Console. See the description of the **Event on** parameter, below.

An event is raised whenever one of the following occurs:

- A threshold that you have specified as an event parameter is exceeded.
- The AD-RT engine can't be initialized. An initialization error is generated, but an Availability or Response Time data stream is not generated.
- The job transaction doesn't complete successfully. A transaction error is generated. Only an Availability data stream is generated, with a value of 0.

4.5.1 Interactive User

You have the option to run this Knowledge Script as "Interactive User," which requires a user to be physically logged into the computer for the test to run. You might want to do this in environments where a firewall is preventing access to an Active Directory domain controller, or where the test computer is part of a workgroup and not part of a domain. With this feature, the user is not validated, so the test can proceed despite the lack of access to the domain. To run as interactive user, type `Interactive User` for the **Run As Username** parameter, and leave the **Password** and **Domain** parameters blank.

4.5.2 Resource Objects

Active Directory response time clients (AD-RT).

4.5.3 Default Schedule

The default interval for this Knowledge Script is **Every 15 minutes**.

4.5.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Availability	
Collect data for availability?	Select the **Yes** check box to collect data for graphs and reports. If enabled, returns: • 1 or 100 – Transaction completed successfully • 0 – Transaction did not complete successfully By default, data is collected.
Data stream format	Select the data stream format for the Availability data stream. Previous versions of AppManager ResponseTime used a 0 (“not available”) or 1 (“available”) format to indicate availability. You now have the option to use a 0 (“not available”) or 100 (“available”) format. The default value is 0-100.
Raise event if transaction fails?	Select the **Yes** check box to raise an event when the server cannot be contacted. By default, events are enabled.
Event severity when transaction fails	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 5. If you disable availability failure events, this value is ignored.
Response Time	
Collect data for response time?	Select the **Yes** check box to collect data for graphs and reports. By default, data is collected.
Threshold – Maximum response time (seconds)	Specify the maximum number of seconds that the transaction can take before an event is raised. The event message contains a breakdown of the total response time. The default is 5 seconds.
Raise event if threshold is exceeded?	Select the **Yes** check box to raise an event when the response time exceeds the threshold. By default, events are raised.
Event severity when threshold is exceeded	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 15.
Host computer	Enter the name of the computer where the service is to be monitored, or click the browse button ([**...**]) to select from a list of available servers. If you’re setting the **Event on** parameter (see below), the **Target computer** parameter also determines the computer where the event will appear in your console. The computer you select must already be in the TreeView.
Event on	Select the TreeView location where events should be displayed. Select either: • **Agent** (the client computer in the response-time tests). This is the default. • **Server** (the server being tested) • **Both**. The event will be shown in two locations in the TreeView. **Notes** This setting does not apply to events related to the Knowledge Script itself, such as Knowledge Script failure or initialization problems. Such events are always displayed on the computer where the job ran. You must select `Agent` when starting jobs in the Operator Web Console. If you select `Server`, no events are generated. If you select `Both`, an event is only shown on the agent.
Service	

Description	How to Set It
Service name	Enter the internal name of the service to query, with no spaces. To find the service name in Windows 2000 or later, open the Control Panel and select **Administrative Tools > Services**. Right-click a service name and select **Properties** in the pop-up window. The **Service name** field appears at the top of the Properties dialog box.
Verify if service is running?	Select the **Yes** check box to query the state of the specified service name and verify whether it is running. By default, the service state is not verified.
Raise event if service is not running?	Select the **Yes** check box to raise an event if the service is not running. By default, events are not raised.
Event severity when service is not running	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 20. If you disable service events, this value is ignored.
Logon and Run As	
Username	Enter the domain username of a user who has Administrator privileges on the host computer. Interactive User is also a possible value. Leave the Password and Domain parameters blank if you specify “Interactive User”.
Password	Enter the password associated with this user. Leave blank to run as “Interactive User.”
Domain	Enter the domain name associated with this user. Leave blank to run as “Interactive User.”
Administrators group on managed client	Enter the name of the Administrators Group on the managed client. Typically, this name is “Administrators”. The default is “`Administrators`”.

4.6 Report_AD-RT

Use this Report Knowledge Script to generate a report detailing availability and response time for the following AD-RT Knowledge Scripts:

- CheckDomainController
- GetObject
- QueryService

4.6.1 Resource Objects

AppManager repository.

4.6.2 Default Schedule

The default schedule is **Run once**.

4.6.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Data Source	Use the following parameters to select the data for your report.
KS for report	Select the Knowledge Script on which to report: 1. Click the **...** button to show the Filter KS List dialog box. 2. Select a filter to narrow the list of Knowledge Scripts and click **OK** to display the list of Knowledge Scripts that met the filter specifications. **NOTE:** If you click **Cancel** from the Filter dialog box, all the Knowledge Scripts are displayed. 3. Highlight an AD-RT Knowledge Script from the **Knowledge Script Name** list and click **Finish**.
AD-RT client(s)	Select the AppManager ResponseTime for Active Directory client(s). Click the **Browse [...]** button to show the Select View(s) and a filter dialog box. From the **View(s)** list, select from one to 25 views. Your subsequent selections are limited to computers or server groups that are visible in the selected views. Select one of the Filters options: • **View:** Includes all computers in the views you selected. • **Computer:** Select from individual computers in the views you selected. • **Server Group:** Select from server groups in the views you selected. Note Selecting a server group includes all computers in that group.
AD Server or “All”	Type the name of the Active Directory server, or type “`All`” to designate all computers as Active Directory servers. The default is the default Active Directory server.

Description	How to Set It
Select time range	In the Select Date/Time Range dialog box, set specific start and end report information dates (good for historical or ad hoc reports), or a sliding range that sets the time range of data to include in the report. The sliding range option is useful for reports running on a regular schedule. It is the default.
Select peak weekday(s)	In the Select Peak Weekday(s) dialog box, while selecting, press **Shift** to select a contiguous day range, or press **Ctrl** to select non-contiguous days.
Aggregation by	Select the time unit by which to aggregate data. The default is Hour. This works in conjunction with the next field (Aggregation interval), which determines the number of units for one interval of data aggregation.
Aggregation interval	Select the interval units in which to aggregate data. The default is 1. For example, if you aggregate by the Hour and select 1 here, data is aggregated once every hour.
Report Settings	Use the following parameters to define the graphical presentation of data, the folder where the report is generated, and properties that identify the report.
Include parameter card?	Select the **Yes** check box to display a table of parameters in the report. By default, the table is displayed.
Include Availability Detail table?	Select the **Yes** check box to display the Availability Detail table as part of the report. By default, the table is included.
Include Availability chart?	Select the **Yes** check box to display the Availability chart as part of the report. By default, the chart is included.
Availability data stream format	Specify the data stream format. Options are 0-100 or 0-1. The default format is 0-100.
Threshold on Availability chart	Enter an integer for the percent. The default is 0 (no threshold is displayed).
Include Response Time Detail table?	Select the **Yes** check box to display the Response Time Detail table as part of the report. By default, the table is included.
Include Response Time chart?	Select the **Yes** check box to display the Response Time chart as part of the report. By default, the chart is included.
Units for Response Time report	Select the response time unit of msec (the default) or sec.
Threshold on Response Time chart (selected units)	Enter the units in seconds > 0, or use the default of 0. (Zero suppresses the threshold indicator in the chart.)
Select chart style	Options in the Chart Settings dialog box set the appearance of the chart. The same parameters are used in both the availability and response time charts, if both are produced. The default is Ribbon.
Select output folder	Select the **...** button to display the Publishing Options dialog box. From this dialog, specify the report filename and the report folder. You can specify a specific folder or have the system generate the folder each time the report runs.
Add job ID to output folder name?	Select the **Yes** check box to add a job ID to the output folder name. By default, the job ID is not added.
Index-Report Title	Select the **...** button to display the Report Properties dialog box. From this dialog, you can configure report title settings and custom fields.
Add timestamp to title?	Specify whether to add a timestamp to the report title.
Event Notification	Use the following parameters to raise events associated with generating the report, and to set severity levels for those events.
Generate event on success?	Select the **Yes** check box to raise an event when a report is generated. By default, events are raised.

Description	How to Set It
Severity level for report success	Set the severity level for a successful report. The default is 35.
Severity level for report with no data	Set the severity level for a report with no data. The default is 25.
Severity level for report failure	Set the severity level for a report with no data. The default is 5.

4.7 Report_AD-RT_DNS

Use this Report Knowledge Script to generate a report detailing availability and response time for the following AD-RT DNS Knowledge Scripts:

- DNSNameLookup
- DNSSpecificServerNameLookup

4.7.1 Resource Objects

AppManager repository.

4.7.2 Default Schedule

The default schedule is **Run once**.

4.7.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Data Source	Use the following parameters to select the data for your report.
KS for report	Select the Knowledge Script on which to report: 1. Click the **...** button to show the Filter KS List dialog box. 2. Select a filter to narrow the list of Knowledge Scripts and click **OK** to display the list of Knowledge Scripts that met the filter specifications. **NOTE:** If you click **Cancel** from the Filter dialog box, all the Knowledge Scripts are displayed. 3. Highlight an AD-RT Knowledge Script from the **Knowledge Script Name** list and click **Finish**.
AD-RT client(s)	Select the AppManager ResponseTime for Active Directory client(s). Click the **Browse [...]** button to show the Select View(s) and a filter dialog box. From the **View(s)** list, select from one to 25 views. Your subsequent selections are limited to computers or server groups that are visible in the selected views. Select one of the Filters options: • **View:** Includes all computers in the views you selected. • **Computer:** Select from individual computers in the views you selected. • **Server Group:** Select from server groups in the views you selected. **NOTE:** Selecting a server group includes all computers in that group.
AD Server or “All”	Type the name of the DNS server, or type “`All`” to designate all computers as DNS servers. The default is the default DNS server.

Description	How to Set It
Select time range	In the Select Date/Time Range dialog box, set specific start and end report information dates (good for historical or ad hoc reports), or a sliding range that sets the time range of data to include in the report. The sliding range option is useful for reports running on a regular schedule. It is the default.
Select peak weekday(s)	In the Select Peak Weekday(s) dialog box, press **Shift** to select a contiguous day range, or **Ctrl** to select non-contiguous days.
Aggregation by	Select the time unit by which to aggregate data. The default is Hour. This works in conjunction with the next parameter (**Aggregation interval**), which determines the number of units for one interval of data aggregation.
Aggregation interval	Select the interval units in which to aggregate data. The default is 1. For example, if you aggregate by the Hour and select 1 here, data is aggregated once every hour.
Report Settings	Use the following parameters to define the graphical presentation of data, the folder where the report is generated, and properties that identify the report.
Include parameter card?	Select the **Yes** check box to display a table of parameters in the report. By default, the table is included.
Include Availability Detail table?	Select the **Yes** check box to display the Availability Detail table as part of the report. By default, the table is included.
Include Availability chart?	Select the **Yes** check box to display the Availability chart as part of the report. By default, the chart is included.
Availability data stream format	Specify the data stream format. Options are 0-100 or 0-1. The default format is 0-100.
Threshold on Availability chart	Enter an integer for the percent. The default is 0 (no threshold is displayed).
Include Response Time Detail table?	Select the **Yes** check box to display the Response Time Detail table as part of the report. By default, the table is included.
Include Response Time chart?	Select the **Yes** check box to display the Response Time chart as part of the report. By default, the chart is included.
Units for Response Time report	Select the response time unit of msec (the default) or sec.
Threshold on Response Time chart (selected units)	Enter the units in seconds > 0, or use the default of 0 (no threshold indicator on the chart).
Select chart style	Options in the Chart Settings dialog box set the appearance of the chart. The same parameters are used in both the availability and response time charts, if both are produced. The default is Ribbon.
Select output folder	Select the **...** button to display the Publishing Options dialog box. From this dialog, specify the report filename and the report folder. You can specify a specific folder or have the system generate the folder each time the report runs.
Add job ID to output folder name?	Select the **Yes** check box to add a job ID to the output folder name. By default, the job ID is not added.
Index-Report Title	In the Report Properties dialog box, configure report title settings.
Add timestamp to title?	Select the **Yes** check box to add a timestamp to the report title.
Event Notification	Use the following parameters to raise events associated with generating the report, and to set severity levels for those events.
Generate event on success?	Select the **Yes** check box to raise an event when a report is generated. By default, events are raised.
Severity level for report success	Set the severity level for a successful report. The default is 35.

Description	How to Set It
Severity level for report with no data	Set the severity level for a report with no data. The default is 25.
Severity level for report failure	Set the severity level for a report with no data. The default is 5.

5 AdvancedAnalytics Knowledge Scripts

Advanced Analytics for AppManager provides the following Knowledge Scripts for monitoring Advanced Analytics resources.

From the Knowledge Script view of Control Center, you can access more information about any Knowledge Script by selecting it and clicking **Help**. In the Operator Console, select any Knowledge Script in the Knowledge Script pane and press **F1**.

Knowledge Script	What It Does
StatusEvents	Monitors the connection between the NetIQ Advanced Analytics Service and AppManager repositories (QDBs) you are monitoring with Advanced Analytics, and also monitors the connection between the service and the AppManager Integration Adapters
EventListener	Inserts events that Advanced Analytics generates into the QDBs that you are monitoring with Advanced Analytics and allows you to view the events in the Control Center console

5.1 StatusEvents

Use this Knowledge Script to monitor the connection between the NetIQ Advanced Analytics Service and QDBs you are monitoring with Advanced Analytics, and also to monitor the connection status between the service and the AppManager Integration Adapters you add to Advanced Analytics. The script automatically raises events to inform you about the connection status. If a QDB or an adapter is not connected to the service, you cannot receive events when a monitored data stream includes data points that fall outside the normal behavior.

Do not run this script as part of a monitoring policy.

5.1.1 Resource Objects

Advanced Analytics server

5.1.2 Default Schedule

By default, this script runs on an asynchronous schedule. All other schedule types are unavailable. Once you start the Knowledge Script job, its runs continuously on the monitored system and reports events as they occur.

5.1.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Event severity when job fails to register with Advanced Analytics Service to receive connection status events	Set the event severity level, from 1-40, to indicate the importance of an event in which the QDB fails to register with the NetIQ Advanced Analytics Service. The default is 5.
Event settings when errors prevent job from running normally	
Event severity when errors prevent job from running normally	Set the event severity level, from 1 to 40, to indicate the importance of an event in which an error prevents the StatusEvents job from running normally. The default is 5. For example, if the Microsoft Message Queue (MSMQ) service stops, the StatusEvents job continues running even though it is not able to retrieve messages from the MSMQ Server.
Time to wait between events when errors prevent job from running normally	Specify the number of minutes, from 1 to 1440 (1 day) to wait between raising events when an error prevents the StatusEvents job from running normally. The default is 10 minutes. For example, if you use the default value of 10, AppManager generates one event every 10 minutes until you resolve the error.
Event severity when QDB and Advanced Analytics Service are connected	Set the event severity level, from 1-40, to indicate the importance of an event in which the NetIQ Advanced Analytics Service is connected to the QDB. The default is 25.

Parameter	How to Set It
Event severity when QDB and Advanced Analytics Service fail to connect	Set the event severity level, from 1-40, to indicate the importance of an event in which the NetIQ Advanced Analytics Service is not connected to the QDB. The default is 5.
Event severity when adapter and Advanced Analytics Service are connected	Set the event severity level, from 1-40, to indicate the importance of an event in which the NetIQ Advanced Analytics Service is connected to the adapter. The default is 25.
Event severity when adapter and Advanced Analytics Service fail to connect	Set the event severity level, from 1-40, to indicate the importance of an event in which the NetIQ Advanced Analytics Service is not connected to the adapter. The default is 5.
Raise event if EventListener job is not running?	Select **Yes** to raise an event if the EventListener job is not running on the QDB. The default is to raise an event.
Time to wait between status checks for the EventListener job	Specify the number of minutes to wait between checks for whether the EventListener job is running on the QDB. The default is 60 minutes. If you select **Yes** for the *Raise event if EventListener job is not running?* parameter and the job is not running on the QDB, AppManager generates one event every *n* minutes. For example, if you use the default value of 60, AppManager generates one event every 60 minutes provided that the job status does not change.
Event severity when EventListener job is not running	Set the event severity level, from 1-40, to indicate the importance of an event in which the EventListener job is not running on the QDB. The default is 5.

5.2 EventListener

Use this Knowledge Script to insert events that Advanced Analytics generates into the QDB and view them in AppManager. If you specify an SMTP server and one or more email recipients, the script sends an SMTP mail message with event information.

Do not run this script as part of a monitoring policy.

5.2.1 Resource Objects

Advanced Analytics server

5.2.2 Default Schedule

By default, this script runs on an asynchronous schedule. All other schedule types are unavailable. Once you start the Knowledge Script job, its runs continuously on the monitored system and reports events as they occur.

5.2.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Event severity when job fails to register with Advanced Analytics Service to receive connection status events	Set the event severity level, from 1-40, to indicate the importance of an event in which the QDB fails to register with the NetIQ Advanced Analytics Service. The default is 5.
Event settings when errors prevent job from running normally	
Event severity when errors prevent job from running normally	Set the event severity level, from 1 to 40, to indicate the importance of an event in which an error prevents the EventListener job from running normally. The default is 5. For example, if the Microsoft Message Queue (MSMQ) service stops, the EventListener job continues running even though it is not able to retrieve messages from the MSMQ Server.
Time to wait between events when errors prevent job from running normally	Specify the number of minutes, from 1 to 1440 (1 day) to wait between raising events when an error prevents the EventListener job from running normally. The default is 10 minutes. For example, if you use the default value of 10, AppManager generates one event every 10 minutes until you resolve the error.
Remove existing Advanced Analytics events when the job starts?	Select **Yes** to remove old Advanced Analytics events from the queue when the job starts. The default is to leave the events in the queue.
Event Notification Options	
Event Notification	

Parameter	How to Set It
Raise event if SMTP server is not accessible?	Select **Yes** to raise an event if the job cannot access the SMTP server in order to send email notifications. The default is to raise an event.
Event severity - SMTP server not accessible	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the job cannot access the SMTP server. The default is 35.
Action	
List of recipient email addresses (semicolon separated)	Provide the full email address for each recipient of the message. Use semicolons (;) to separate multiple recipient addresses. For example: `chris@abc.com;pat@def.com;jw@abc.com`. The following characters are invalid: `/ \ [ ] : | = , * ? < >`
Sender's email address	Provide the email address of the person sending the message. The following characters are invalid: `/ \ [ ] : | = , * ? < >`
SMTP server name	Provide the host name or IP address of your SMTP server.
SMTP port	Set the port number for your SMTP server. The default is 25.
Message format	Select the format you want to use for the message sent by this script: • Standard format generates a message based upon the selections you make from the **Standard Message Options** parameters. • Custom format generates a message based upon the subject and message body you supply in the **Custom Message Options** parameters. The default is Standard.
Standard Message Options	
Include date/timestamp?	Select **Yes** to include the date/timestamp in the standard message. The default is to exclude the date/timestamp.
Include JobID?	Select **Yes** to include the job ID in the standard message. The default is to exclude the job ID.
Include agent computer name?	Select **Yes** to include the name of the agent computer that initiated the action in the standard message. The default is to include the computer name.
Include event severity?	Select **Yes** to include the severity of the event in the standard message. The default is to include the severity.
Include Knowledge Script name?	Select **Yes** to include the name of the Knowledge Script that initiated the action in the standard message. The default is to exclude the Knowledge Script name.
Include AppManager object name?	Select **Yes** to include the name of the resource object where the event was raised in the standard message. The default is to exclude the object name.
Include AppManager event ID (only on MS action)?	Select **Yes** to include the AppManager event ID in the standard message, possible only in cases when the management server carries out the action. The default is to exclude the event ID.
Include event detail message?	Select **Yes** to include the event detail message. The default is to exclude the detail message.
Custom Message Options	
Custom message subject	Provide the text you want to use for the custom message subject line.

Parameter	How to Set It
Custom message body	Provide the text you want to include in your custom message. You can use the keywords listed below to indicate the information you want to include in the body of your custom message. Add a space before and after keywords to ensure that the keywords display properly. • `$ShortMsg$` (short event message). • `$DetailMsg$` (detailed event message). • `$Time$` (date and time of the event). • `$JobID$` (ID of the job that raised the event). • `$MachineName$` (name of the computer where the event was raised). • `$Severity$` (severity of the event). • `$KSName$` (name of the Knowledge Script that raised the event). • `$ObjectName$` (name of the AppManager resource object where the event was raised). • `$EventID$` (event ID). • `$tab$` inserts four whitespace characters in the message body. • `$lf$` inserts a line feed in the message body. • `$crlf$` inserts a carriage-return line feed in the message body. • `$cr$` inserts a carriage-return in the message body. For `$ShortMsg$` and `$DetailMsg$` you can use number and wildcard options to indicate specific portions of the text string to include. For example: • `$DetailMsg$[5]` includes the fifth word of the detailed event message. • `$ShortMsg$[1-5]` includes the first through fifth words of the short event message. • `$DetailMsg$[*5]` includes the first through fifth words of the detailed event message. • `$ShortMsg$[5*]` includes the fifth through last words of the short event message. This script treats the following character values as separators between words: carriage return, line feed, carriage return/line feed combination, form feed, horizontal tab, and space. Everything between those character values in a custom message is considered a word. If you do not enter a keyword, AppManager returns the entire string. The following are examples of the types of messages you can construct using keywords: • Event from `$MachineName$`: The `$ShortMsg$[1-3]` has failed. The last command was `$DetailMsg$[4*]`. • A severity `$Severity$` event has occurred. Call the owner of `$MachineName$` immediately.

6 Agentless Knowledge Scripts

AppManager for Agentless Monitoring module provides Knowledge Scripts for monitoring remote Windows and UNIX computers without the need to have the AppManager agent installed on them.

In addition to the Agentless Monitoring Knowledge Scripts that help you monitor the remote computer resources, this module also provides the link linkend="Agentless_MonitoringInterval"Agentless_MonitoringInterval /linkKnowledge Script to set the time interval for monitoring.

Before you run any Agentless Monitoring Knowledge Script, you must run the Agentless_MonitoringInterval Knowledge Script with the *Monitoring Interval* parameter set to the desired value. For example, if you want the monitoring service to monitor remote computers every five minutes, run the Agentless_MonitoringInterval Knowledge Script with the *Monitoring Interval* parameter set to five minutes. For more information about the Agentless_MonitoringInterval Knowledge Script, see "MonitoringInterval " on page 238.

From the Knowledge Script view of Control Center, you can access more information about any Knowledge Script by selecting it and clicking **Help**. In the Operator Console, select any Knowledge Script in the Knowledge Script pane and press **F1**.

By default, the Agentless Monitoring Knowledge Scripts runs at regular intervals of five minutes. NetIQ Corporation recommends that you should not set this time interval below the value you set for the *Monitoring Interval* parameter in the Agentless_MonitoringInterval Knowledge Script to avoid duplicate data points.

Agentless Knowledge Script	What It Does
CPUUtilization	Monitors overall CPU usage and queue length to determine the CPU load.
DiskSpace	Monitors logical disks for the percentage of disk space used and the amount of disk free space in megabytes.
MemoryUtilization	Monitors physical memory usage.
MonitoringInterval	Sets the monitoring interval at which the Agentless monitoring service should monitor the remote computers.
NetworkUtilization	Monitors network utilization for network interface cards (NICs).
RemoteComputerStatus	Checks remote computer availability for monitoring. The Agentless_CPUUtilization, Agentless_DiskSpace, and Agentless_MemoryUtilization Knowledge Scripts also let you check the availability of the remote computer for monitoring. However, NetIQ Corporation recommends that you use the Agentless_RemoteComputerStatus Knowledge Script to monitor remote computer availability.

6.1 Monitoring Remote Computers Having Different Threshold Values

You can use a single monitoring job to monitor multiple remote computers that have different threshold values. When you run the monitoring job, you must provide the full path to the threshold file that contains the threshold values for individual computers. If the computer you want to monitor does not have an entry in the threshold file, the job uses the threshold values specified in the Knowledge Script.

6.1.1 Creating the Threshold File

Use a spreadsheet program such as Microsoft Excel to create a threshold file and save the file as a `.csv` file. You must create a separate threshold file for every Knowledge Script. Every row in this file must list the following values separated by comma and no spaces:

- Identifier of the computer (NetBIOS, FQDN, or IP Address) you want to monitor
- The threshold values for the Knowledge Script metrics

KnowledgeScript and Metrics	Threshold File Entry Per Computer	Examples
CPUUtilization • Maximum threshold for CPU usage • Maximum threshold for CPU queue length	*computer_identifier*,*CPU_Usage_max_thresholdvalue*,*CPU_QueueLength_max_t*	• Computer1,60,3 • 10.0.0.0,80,5
DiskSpace • Minimum threshold for logical disk free space in MB • Minimum per-disk threshold for logical disk free space in MB • Maximum threshold for logical disk space usage in % • Maximum per-disk threshold for logical disk space usage in %	*computer_identifier*,*disk_freespace_min_thresholdvalue*,*per_disk_freespa*	• 10.0.0.60,8800,/=9890;/boo • Computer2,9500,C:=8600;E:= **NOTE:** Use semicolon to specify multiple disk drives.
MemoryUtilization • Maximum threshold for physical memory usage	*computer_identifier*,*physical_memory_Usage_max_thresholdvalue*	• Computer3,70 • 10.0.0.7,80
NetworkUtilization • Maximum threshold for network utilization	*computer_identifier*,*network_Usage_max_thresholdvalue*	• Computer1,45 • 10.0.0.7,30

Use a hash symbol (#) to comment lines in the threshold file.

6.1.2 Understanding the Threshold Values Format

If the threshold values specified in the threshold file is not in a valid format, the monitoring job does one the following based on the scenario:

- Not enough threshold values or no threshold values listed in the threshold file: To monitor computers that have less number of threshold value entries in the file, the monitoring job uses all the valid threshold values specified for the computer in the file. For any threshold value that is either missing or invalid in the file, the job uses the corresponding threshold value specified in the Knowledge Script.
- Correct number of threshold values listed in the threshold file, but one or more values are not in valid format: The monitoring job generates an event. To monitor computers that have invalid threshold value entries in the file, the monitoring job uses all the valid threshold values specified in the file. For any invalid threshold value in the file, the job uses the corresponding threshold value specified in the Knowledge Script.
- More number of threshold values listed in the threshold file: The monitoring job generates an event. To monitor computers that have more number of threshold value entries in the file, the monitoring job skips all the threshold values specified in the file and uses the corresponding threshold values specified in the Knowledge Script.

6.2 CPUUtilization

Use this Knowledge Script to monitor overall CPU usage and queue length to determine whether the CPU is overloaded. This script raises an event when the CPU usage and CPU queue length values exceed the thresholds you set.

6.2.1 Resource Objects

CPU object

6.2.2 Default Schedule

The default schedule for this script is **Every 5 minutes**.

6.2.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
General Settings	
Job Failure Notification	
Event severity when job fails unexpectedly	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the CPUUtilization job fails. The default is 5.
Unavailable Data Points	
Raise event if the remote computer is not available for monitoring?	Select **Yes** to raise an event if the remote computer is not available for monitoring. The default is No. NetIQ Corporation recommends you use the Agentless_RemoteComputerStatus Knowledge Script to check the availability status of the remote computer you want to monitor. If you select **Yes** for this parameter and run the Agentless_RemoteComputerStatus Knowledge Script, you might encounter duplicate events, one raised by this Knowledge Script and the other by Agentless_RemoteComputerStatus Knowledge Script.
Event severity when the remote computer is not available for monitoring	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the remote computer is not available for monitoring. The default is 15.
Raise event if CPU metrics are not available beyond the threshold time?	Select **Yes** to raise an event if the CPU metrics are not available even after the threshold time is reached.The default is No.
Maximum threshold time since the last collected data point	Specify the maximum wait time from the time the last data point is collected before an event is raised. The default is 10 minutes.
Event severity when CPU metrics are not available beyond the threshold time	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the CPU metrics are not available even after the threshold time is reached. The default is 15.

Description	How to Set It
Threshold Values For Individual Computers	
Full path to file containing threshold values	Provide the full path to the threshold file containing the maximum threshold values for overall CPU usage and queue length. For information about creating the threshold file, see "Creating the Threshold File" on page 228.
Raise event if the threshold values specified for a computer are not in valid format?	Select **Yes** to raise an event if the threshold values specified for a computer are not in valid format. The default is Yes. For information about the threshold values format, see "Understanding the Threshold Values Format" on page 228.
Event severity when the threshold values specified for a computer are not in valid format?	Set the event severity level, from 1 to 40, to indicate the importance of an event in which threshold values specified for a computer are not in valid format. The default is 15.
Additional Settings	
Event Details	
Event detail format	Select whether to view event details in an **HTML Table** or in **Plain Text**. The default is HTML Table.
Monitor CPU Usage	
Event Notification	
Raise event if overall CPU usage exceeds the threshold?	Select **Yes** to raise an event if overall CPU usage exceeds the threshold you set. The default is Yes.
Maximum threshold for overall CPU usage	Specify the maximum overall CPU usage that can occur before an event is raised. The default is 95%.
Event severity when overall CPU usage exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the percentage of the CPU usage exceeds the threshold. The default is 15.
Data Collection	
Collect data for overall CPU usage?	Select **Yes** to collect data about the percentage of CPU usage for charts and reports. The default is unselected.
Monitor CPU Queue Length	
Event Notification	
Raise event if processor queue length exceeds the threshold?	Select **Yes** to raise an event if maximum processor queue length exceeds the threshold you set. The default is Yes.
Maximum threshold for processor queue length	Specify the maximum number of processes the CPU queue can contain before an event is raised. CPU queue length indicates how many processes are ready to run. The default is 2 processes.
Event severity when processor queue length exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which processor queue length usage exceeds the threshold. The default is 15.
Data Collection	

Description	How to Set It
Collect data for processor queue length?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the number of threads waiting to execute on all processors. The default is unselected. The detail data contains information about processor queue length and the threshold for processor queue length.

6.3 DiskSpace

Use this Knowledge Script to monitor logical drives for the percentage of disk space used and the amount of free space in megabytes.

Each time you run this script, it automatically monitors all logical disks on a server. You can also provide a list of drives to exclude from monitoring.

This script raises an event if the percentage of used space exceeds the threshold you set, or the amount of free space falls below the threshold you set.

6.3.1 Resource Object

Logical disk drive

6.3.2 Default Schedule

The default schedule for this script is **Every 5 minutes**.

6.3.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Job Failure Notification	
Event severity when job fails unexpectedly	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the DiskSpace job fails. The default is 5.
Unavailable Data Points	
Raise event if the remote computer is not available for monitoring?	Select **Yes** to raise an event if the remote computer is not available for monitoring. The default is No. NetIQ Corporation recommends you use the Agentless_RemoteComputerStatus Knowledge Script to check the availability status of the remote computer you want to monitor. If you select **Yes** for this parameter and run the Agentless_RemoteComputerStatus Knowledge Script, you might encounter duplicate events, one raised by this Knowledge Script and the other by Agentless_RemoteComputerStatus Knowledge Script.
Event severity when the remote computer is not available for monitoring	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the remote computer is not available for monitoring. The default is 15.
Raise event if logical disk metrics are not available beyond the threshold time?	Select **Yes** to raise an event if the logical disk metrics are not available even after the threshold time is reached.The default is No.

Parameter	How to Set It
Maximum threshold time since the last collected data point	Specify the maximum wait time from the time the last data point is collected before an event is raised. The default is 10 minutes.
Event severity when logical disk metrics are not available beyond the threshold time	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the logical disk metrics are not available even after the threshold time you set is reached. The default is 15.
Threshold Values For Individual Computers	
Full path to file containing threshold values	Provide the full path to the threshold file containing the maximum threshold values for percentage of disk space used and the amount of free space in megabytes. For information about creating the threshold file, see "Creating the Threshold File" on page 228.
Raise event if the threshold values specified for a computer are not in valid format?	Select **Yes** to raise an event if the threshold values specified for a computer are not in valid format. The default is Yes. For information about the threshold values format, see "Understanding the Threshold Values Format" on page 228.
Event severity when the threshold values specified for a computer are not in valid format?	Set the event severity level, from 1 to 40, to indicate the importance of an event in which threshold values specified for a computer are not in valid format. The default is 15.
Additional Settings	
Event Details	
Event detail format	Select whether to view event details in an **HTML Table** or in **Plain Text**. The default is HTML Table.
Monitor Disk Space	
Drives to exclude	Provide a comma-separated list of the drives you do not want to monitor. This script automatically monitors all drives except those listed in this parameter. For example: • `C:,E:` In this example, the script automatically monitors all drives except C and E drives on a Windows computer. • `/boot,/` In this example, the script automatically monitors all drives except the boot drive and root drive on a UNIX computer.
Event Notification	
Raise separate events for individual drives?	Select **Yes** to raise separate events for individual drives. The default is unselected. When you enable this parameter, the script raises separate events that detail the disk usage for each monitored logical drive.
Raise event if logical disk free space falls below the threshold?	Select **Yes** to raise an event if the amount of available disk space falls below the threshold you set. The default is Yes. When you enable this parameter, the script raises one event that details the available disk space for all monitored logical drives.

Parameter	How to Set It
Minimum threshold for logical disk free space	Specify the minimum amount of disk space that must be available to prevent an event from being raised. The default is 100 MB. This threshold applies to all disks unless you provide a per-disk threshold value in the *Minimum per-disk threshold for logical disk free space in MB* parameter.
Minimum per-disk threshold for logical disk free space in MB	Specify the minimum amount of disk space that must be available on individual disks to prevent an event from being raised. Use commas to separate multiple thresholds. For example: • `C:=90500,D:=550` In this example, the threshold for minimum disk space on the C: disk is 90500 MB. The threshold for the D: disk is 550 MB. • `/boot=500,/=2500` In this example, the threshold for minimum disk space on /boot is 500 MB. The threshold for root is 2500 MB.
Event severity when logical disk free space falls below the threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the amount of available disk space falls below the threshold you set. The default is 15.
Raise event if logical disk space usage exceeds the threshold?	Select **Yes** to raise an event if the percentage of disk utilization exceeds the threshold you set. The default is Yes. When you enable this parameter, the script raises one event that details the disk usage for all monitored logical drives.
Maximum threshold for logical disk space usage	Specify the maximum percentage of disk utilization that can occur before an event is raised. The default is 90%. This threshold applies to all disks unless you provide a per-disk threshold value in the *Maximum per-disk threshold for logical disk space usage in %* parameter.
Maximum per-disk threshold for logical disk space usage in %	Specify the maximum percentage of disk utilization that can occur on individual disks before an event is raised. Use commas to separate multiple thresholds. For example: For example: • `C:=50,D:=80` In this example, the threshold for maximum disk utilization on the C: disk is 50%. The threshold for the D: disk is 80%. • `/boot=35,/=20` In this example, the threshold for maximum disk utilization on /boot is 35 MB. The threshold for root is 20 MB.
Event severity when logical disk space usage exceeds the threshold?	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the percentage of disk utilization exceeds the threshold you set. The default is 15.
Data Collection	
Collect data for logical disk free space	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the amount of available disk space for the selected drives. The default is unselected.
Collect data for logical disk usage?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns utilization details for used space (%). The default is unselected.

6.4 MemoryUtilization

Use this Knowledge Script to monitor the usage of physical memory. This script raises an event if the physical memory usage exceeds the threshold. In addition, this script generates data streams for the physical memory usage.

6.4.1 Resource Objects

Physical memory object

6.4.2 Default Schedule

The default schedule for this script is **Every 5 minutes**.

6.4.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
General Settings	
Job Failure Notification	
Event severity if job fails unexpectedly	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the MemoryUtilization job fails. The default is 5.
Unavailable Data Points	
Raise event if the remote computer is not available for monitoring?	Select **Yes** to raise an event if the remote computer is not available for monitoring. The default is No. NetIQ Corporation recommends you use the Agentless_RemoteComputerStatus Knowledge Script to check the availability status of the remote computer you want to monitor. If you select **Yes** for this parameter and run the Agentless_RemoteComputerStatus Knowledge Script, you might encounter duplicate events, one raised by this Knowledge Script and the other by Agentless_RemoteComputerStatus Knowledge Script.
Event severity when the remote computer is not available for monitoring	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the remote computer is not available for monitoring. The default is 15.
Raise event if memory metrics are not available beyond the threshold time?	Select **Yes** to raise an event if the memory metrics are not available even after the threshold time you set is reached.The default is No.
Maximum threshold time since the last collected data point	Specify the maximum wait time from the time the last data point is collected before an event is raised. The default is 10 minutes.
Event severity when memory metrics are not available beyond the threshold time	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the memory metrics are not available even after the threshold time you set is reached. The default is 15.

Description	How to Set It
Threshold Values For Individual Computers	
Full path to file containing threshold values	Provide the full path to the threshold file containing the maximum threshold values for physical memory usage. For information about creating the threshold file, see "Creating the Threshold File" on page 228.
Raise event if the threshold values specified for a computer are not in valid format?	Select **Yes** to raise an event if the threshold values specified for a computer are not in valid format. The default is Yes. For information about the threshold values format, see "Understanding the Threshold Values Format" on page 228.
Event severity when the threshold values specified for a computer are not in valid format?	Set the event severity level, from 1 to 40, to indicate the importance of an event in which threshold values specified for a computer are not in valid format. The default is 15.
Additional Settings	
Event Details	
Event detail format	Select whether to view event details in an **HTML Table** or in **Plain Text**. The default is HTML Table.
Monitor Physical Memory Usage	
Event Notification	
Raise event if physical memory usage exceeds the threshold?	Select **Yes** to raise an event if physical memory usage exceeds the threshold you set. The default is Yes.
Maximum threshold for physical memory usage	Specify the maximum percentage of physical memory that can be in use before an event is raised. The default is 90%.
Event severity when physical memory usage exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the physical memory usage exceeds the threshold. The default is 15.
Data Collection	
Collect data for physical memory usage?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the percentage of physical memory usage during the monitoring period. The default is unselected.

6.5 MonitoringInterval

Before you run any Agentless Monitoring Knowledge Script, you must run the Agentless_MonitoringInterval Knowledge Script with the *Monitoring Interval* parameter set to the desired value. For example, if you want the monitoring service to monitor remote computers every five minutes, run the Agentless_MonitoringInterval Knowledge Script with the *Monitoring Interval* parameter set to the default five minutes.

6.5.1 Resource Objects

NT_MachineFolder

6.5.2 Default Schedule

By default, this script runs once.

6.5.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
General Settings	
Monitoring Interval	Specify how often you want the Agentless monitoring service to monitor the remote computers. The default is 5 minutes.
Additional Settings	
Event Details	
Event detail format	Select whether to view event details in an **HTML Table** or in **Plain Text**. The default is HTML Table.
Raise event if monitoring interval changed successfully?	Select **Yes** to raise an event if the monitoring interval has successfully changed. The default is Yes.
Event severity when monitoring interval changed successfully	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the monitoring interval successfully changed. The default is 25.
Raise event if monitoring failed to change?	Select **Yes** to raise an event if the monitoring interval failed to change. The default is Yes.
Event severity when monitoring interval failed to change	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the monitoring interval failed to change. The default is 5.

6.6 NetworkUtilization

Use this Knowledge Script to monitor the percentage of data sent or received over the network. This script raises an event if the network utilization exceeds the threshold. In addition, this script generates data streams for the network usage.

6.6.1 Resource Objects

Network interface folder

6.6.2 Default Schedule

The default schedule for this script is **Every 5 minutes**.

6.6.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
General Settings	
Job Failure Notification	
Event severity when job fails unexpectedly	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the NetworkUtilization job fails. The default is 5.
Unavailable Data Points	
Raise event if the remote computer is not available for monitoring?	Select **Yes** to raise an event if the remote computer is not available for monitoring. The default is No. NetIQ Corporation recommends you use the Agentless_RemoteComputerStatus Knowledge Script to check the availability status of the remote computer you want to monitor. If you select **Yes** for this parameter and run the Agentless_RemoteComputerStatus Knowledge Script, you might encounter duplicate events, one raised by this Knowledge Script and the other by Agentless_RemoteComputerStatus Knowledge Script.
Event severity when the remote computer is not available for monitoring	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the remote computer is not available for monitoring. The default is 15.
Raise event if network metrics are not available beyond the threshold time?	Select **Yes** to raise an event if the network metrics are not available even after the threshold time you set is reached.The default is No.
Maximum threshold time since the last collected data point	Specify the maximum wait time from the time the last data point is collected before an event is raised. The default is 10 minutes.
Event severity when network metrics are not available beyond the threshold time	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the network metrics are not available even after the threshold time you set is reached. The default is 15.

Description	How to Set It
Threshold Values For Individual Computers	
Full path to file containing threshold values	Provide the full path to the threshold file containing the maximum threshold values for network usage. For information about creating the threshold file, see "Creating the Threshold File" on page 228.
Raise event if the threshold values specified for a computer are not in valid format?	Select **Yes** to raise an event if the threshold values specified for a computer are not in valid format. The default is Yes. For information about the threshold values format, see "Understanding the Threshold Values Format" on page 228.
Event severity when the threshold values specified for a computer are not in valid format?	Set the event severity level, from 1 to 40, to indicate the importance of an event in which threshold values specified for a computer are not in valid format. The default is 15.
Additional Settings	
Event Details	
Event detail format	Select whether to view event details in an **HTML Table** or in **Plain Text**. The default is HTML Table.
Monitor Network Utilization	
Event Notification	
Network interfaces to exclude	List the display names of all active network interfaces that you do not want to monitor. Separate each interface name with a comma and without any spaces. You can use the asterisk (*) as a wildcard along with regular expressions for interface names. The default is: `*Loopback*,*Pseudo*,*isatap*,*tunnel*`. These settings exclude the set of interfaces that are part of the operating system and do not map to actual network cards.
Raise event if network utilization exceeds the threshold?	Select **Yes** to raise an event if network usage exceeds the threshold you set. The default is Yes.
Maximum threshold for network utilization	Specify the maximum percentage of network usage that can be in use before an event is raised. The default is 35%.
Event severity when network utilization exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the network usage exceeds the threshold. The default is 15.
Data Collection	
Collect data for network utilization?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the percentage of network usage during the monitoring period. The default is unselected.

6.7 RemoteComputerStatus

Use this Knowledge Script to check if the remote computer that you want to monitor is available for monitoring. This Knowledge Script raises the following events depending on the availability status of the remote computer:

Event Raised	What it means
Monitoring Health Error: The network path was not found	The remote computer is not in the network, or the remote computer is not up and running.
Monitoring Health Error: Access is denied	The user whose credentials are specified does not have sufficient permissions to access the performance counter from the remote computer.
The RPC server is too busy to complete this operation VM_NetworkInterface_PacketsPerSecond	The Remote Procedure Call (RPC) service on the remote computer is busy. Restart the service.

6.7.1 Resource Objects

Windows or UNIX remote computer(s)

6.7.2 Default Schedule

The default schedule for this script is **Every 5 minutes**.

6.7.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
General Settings	
Job Failure Notification	
Raise severity if job fails unexpectedly?	Select **Yes** to raise an event if the RemoteComputerStatus job fails. The default is Yes.
Event severity when job fails unexpectedly	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the RemoteComputerStatus job fails. The default is 5.
Additional Settings	
Event Details	
Event detail format	Select whether to view event details in an **HTML Table** or in **Plain Text**. The default is HTML Table.
Remote Computer Availability	
Event Notification	
Raise event if remote computer is not available for monitoring?	Select **Yes** to raise an event if the remote computer you want to monitor is not available for monitoring. The default is Yes.

Description	How to Set It
Event severity when remote computer is not available for monitoring	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the remote computer you want to monitor is not available for monitoring. The default is 15.
Data Collection	
Collect data for remote computer availability?	Select **Yes** to collect remote computer availability data for charts and reports. If enabled, data collection returns: • 100: Remote computer is available for monitoring • 0: Remote computer is not available for monitoring The default is unselected.

7 AMAdmin Knowledge Scripts

The NT category contains Knowledge Scripts that perform administrative tasks for Windows agents and your AppManager site. To run Knowledge Scripts in this category, your user account needs administrator privileges.

From the Knowledge Script view of Control Center, you can access more information about any NetIQ-supported Knowledge Script by selecting it and clicking **Help**. In the Operator Console, click any Knowledge Script in the Knowledge Script pane and press **F1**.

Knowledge Script	What It Does
AgentConfigMSRestrictions	Configures the agent restrictions for communicating with management servers.
AgentConfigSecurityKey	Updates the security key file on a managed client computer.
AgentConfigSecurityLevel	Configures the security level for the AppManager agent remotely on Windows computers in your network.
AgentHealth	Monitors the Windows Application log for self-monitoring events raised by the agent services (`NetIQmc` and `NetIQccm`).
AgentSelfMon	Monitors the health of the scripting engine on the AppManager agent on a Windows computer.
ChangeFooter	Changes the graphic and hyperlink that appear at the bottom of each report page.
ConcurrentRpt	Queries the registry on a computer where you have installed a report agent to get or set the number of concurrent reports.
ConfigAdminEvents	Updates the registry with severity settings for AppManager agent and Management Service events
ConfigSiteCommType	Configures communication between managed client computers and the management server.
ConfigSiteNetFlowCtrl	Configures the size and frequency of agent communications with the management server.
DBHealth	Monitors SQL Server resources associated with the AppManager repository.
DeleteExpiredReports	Deletes expired reports generated by an AppManager report agent.
DisableSiteComm	Temporarily disables network communication from a managed client on Windows to the current management server and saves messages (including events, data, and job status) in the managed client's local repository.
EnableSiteComm	Resumes regular ongoing network communication from a managed client on Windows to the management server.
GreyMachines	Monitors AppManager agents that do not respond to management server Ping requests.

IISContinueSite	Continues a paused Internet Information Services (IIS) site.
IISPauseSite	Pauses an Internet Information Services (IIS) site.
IISRestartServer	Restarts an Internet Information Services (IIS) server.
IISRestartSite	Restarts an Internet Information Services (IIS) site.
LRReadParameters	Raises an event that displays local repository (LR) configuration information of a managed client computer.
LRRemoveParameters	Removes local repository (LR) configuration information from a managed client computer.
LRWriteParameters	Stores local repository (LR) configuration information in a managed client computer.
MonitorMSCommunications	Monitors the Windows Application log for events that indicate the agent and the management server are not using compatible encryption keys.
MSHealth	Monitors the Windows Application log for events generated by the agent service and the management server.
RemovePrimaryMS	Removes a designated primary management server from a managed client on Windows.
SchedMaint	Sets an application server maintenance period for a managed computer on Windows. During the maintenance period, regularly scheduled AppManager jobs can be prevented from running.
SetAllowMS	Restricts the management servers that can control a particular agent in sites with multiple management servers or multiple repositories.
SetDataTimeStamp	Sets the timestamp for data as it is referenced for reports. This setting affects all reports, but it does not affect areas other than reporting.
SetDeploymentWebService	Sets or changes the deployment Web service with which the managed client communicates to install the agents remotely.
SetKSStandby	Designates a selected managed client as a standby managed client for specified Knowledge Script categories and for the master managed client.
SetLocalRPSize	Modifies the maximum number of events or data points that can be stored in the local repository of a managed client on Windows.
SetPrimaryMS	Sets the primary management server for a managed client on Windows in multiple management server configurations.
SetReportPaths	Sets the output path of the Report Agent. Sets the URL Mapping registry value so that the paths to reports are displayed as hyperlinks in report event messages.
SetResDependency	Defines the resources required to run Knowledge Script jobs on Windows computers.
SiteSchedUpload	Specifies a schedule for uploading data and/or events from the local repository of a managed client on Windows to the current management server. Sets up specific schedules for data, events, or both.
UpgradeJobs	Upgrades all child jobs for a specified parent job on managed Windows or UNIX servers to the latest Knowledge Script version.

7.1 AgentConfigMSRestrictions

Use this Knowledge Script to check for and configure agent restrictions for communicating with management servers. By default, this script raises an event if an agent is configured to allow communication with anonymous management servers.

You should restrict the management servers from which an AppManager agent will accept job requests to ensure that only authorized management servers communicate with the agent.

An *anonymous* management server is a management server with which the agent has not explicitly authorized communication.

The list of management servers with which the agent communicates is stored in the following registry key:

`\HKEY_LOCAL_MACHINE\SOFTWARE\NetIQ\4.0\NetIQMC\Security\AllowMS`

If the value of this key is * (asterisk), the agent allows anonymous communication.

7.1.1 Resource Objects

Windows 2000 Server or later

7.1.2 Default Schedule

The default interval for this script is **Run once**.

7.1.3 About Authorizing Management Servers

When you upgrade the agent to AppManager 7.x, the upgrade process allows you to automatically restrict the authorized servers to the designated primary and secondary, or keep the current configuration until you change the agent's designated primary and secondary management server using the SetPrimaryMS script. If you do not change the management server designation during the upgrade, you can use this script after you upgrade to restrict the authorized management servers.

AppManager 7.0 (or later) agents by default are configured to authorize communication with their designated primary and secondary management servers. If you did not designate the primary and secondary management server during installation, you can use this script after installation to restrict the authorized management servers.

7.1.4 Authorizing Management Servers in a Single-Site Configuration

If you are managing a client computer from a single AppManager site (repository), you should restrict the authorized management servers to the agent's designated primary and secondary management server.

7.1.5 Authorizing Management Servers in a Multiple-Site Configuration

Within a site, after you designate an agent's primary and secondary management server, the agent receives job information and sends events and data only to its designated primary or secondary management server. However, if you have more than one AppManager site, you may want to allow the agent to accept job requests from another site. To do so, you can use this script to authorize the management servers from each site.

When allowing the agent to accept communication from additional management servers, make sure you choose the **Append** option to **add** the management servers to the authorized list (instead of replacing the existing list of authorized management servers). This will allow you to run the SetPrimaryMS script on the agent from the other site and properly configure the agent to accept communication from management servers in both sites.

7.1.6 Reading the Current Configuration

If you are unsure of the agent settings, view the current configuration by choosing **Read configuration** from the *Select operation* parameter and selecting an option to raise an event:

- **If an insecure configuration is detected** – The event message indicates the agent's configuration allows anonymous management server communication. If you choose this option, you can also set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 10.
- **To report current configuration** – The event message indicates the agent configuration. If you choose this option, you can also set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.

When reading the current configuration, by default this script raises an event of severity level 10 if an insecure configuration is detected.

This script always raises an event if the job fails.

This script raises an event for each agent to report the agent's configuration. To view the results, click the **Message** tab.

The event message contains the following sections:

- **Current configuration** – Indicates whether the agent allows anonymous communication (that is, communication with management servers with which the agent has not explicitly authorized communication).

Result	What It Means
Never allow anonymous MS	The agent is configured to restrict anonymous management server communication. You must run this script to allow anonymous management server communication. This result only applies to version 7.0 (or later) agents.
Do not allow anonymous MS at this time	The agent is configured to restrict anonymous communication.
Allow anonymous MS until Primary/Secondary MS is set	The agent is configured to allow anonymous communication until you designate a primary management server. If the agent that has not been configured to have a designated primary server, select this option to secure management server communication after the primary management server is designated.
Allow anonymous MS at this time	The agent is configured to remove restrictions on anonymous management server communication. This setting is not recommended.

- **Specified management servers currently allowed to communicate with this agent** – Lists the management servers that are authorized to communicate with the agent.

  If this section lists the value as **[Blank]**, the agent does not have an authorized list of management servers with which to communicate. In this case, the agent can still communicate with its designated primary and secondary management server. We recommend that you authorize the agent to communicate with its primary and secondary management server.

7.1.7 Changing the Current Configuration

To change the current configuration, choose **Write configuration** from the *Select operation* parameter and specify the following parameters. By default, this script reads the configuration.

This script always raises an event if the job fails.

Set or change the following parameters as needed:

Parameter	How to Set It
Write Options	
Restrict management server communication	Select an option to restrict management server communication: • **Never allow anonymous MS** – For AppManager 7.0 (or later) agents, this option restricts anonymous management server communication. **TIP:** To configure an agent to allow anonymous communication, run this script and select the **Allow anonymous MS at this time** option. If you choose this option, make sure the agent is configured to authorize communication with at least one management server. This is the default. • **Do not allow anonymous MS at this time** – This option restricts anonymous communication for all versions of the agent. • **Allow anonymous MS until Primary/Secondary MS is set** – This restricts anonymous management server communication after the primary management server is designated. If the agent that has not been configured to have a designated primary server, select this option to allow anonymous communication until you designate a primary management server. • **Allow anonymous MS at this time** – This option removes restrictions on anonymous management server communication. This setting is not recommended.
List of authorized management servers	Specify the management servers you want to authorize: • **Management servers to include** – Specify a comma-separated list of the management servers with which you want the agent to communicate. • **Append or replace current list?** – Select one of the following options: **Append** to add your specified management servers to the list of authorized management servers. This is the default. **Replace** to remove the existing list of authorized management servers and replace with your specified management servers. • **Management servers to remove** – Specify a comma-separated list of the management servers with which you do **not** want the agent to communicate.

Parameter	How to Set It
Event notification	Set this script to raise an event and specify the severity if: • **Configuration succeeds –** Select the **Yes** check box to raise an event if the configuration succeeds. When enabled, lets you also set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 20 (yellow event indicator). By default, this option is enabled. • **Configuration failed** – Select the **Yes** check box to raise an event if the configuration fails. When enabled, lets you also set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 10 (red event indicator). By default, this option is enabled.

7.1.8 Avoiding Orphaned Agents

If you use this script to remove or replace the list of authorized management servers and the agent is configured to never allow anonymous management server communication, make sure you authorize at least one valid management server. If the agent is configured to never allow anonymous management server communication and the agent is not configured to authorize a management server, the agent cannot be managed by AppManager.

To resolve this problem, manually edit the registry on the managed client computer to specify an authorized management server list in `\HKEY_LOCAL_MACHINE\SOFTWARE\NetIQ\4.0\NetIQMC\Security\AllowMS`.

7.2 AgentConfigSecurityKey

Use this Knowledge Script to remotely update the security key information on your managed Windows computers in an AppManager site if you are using encrypted communication or authentication and encryption to secure communication between management servers and managed clients.

Within an AppManager site, all management server computers and managed Windows clients must use the same security key information. This key information is stored in the repository and extracted from the repository into an encrypted and password-protected agent key file. You can then use this script to distribute this password-protected key file to remote agents. If the AppManager repository has different key information than an AppManager agent, agent will not be able to decrypt information from the management server and communication will fail.

NOTE: Use this script only to distribute the key file to managed Windows clients. You must create the key information and the agent key file separately before using this script. In most cases, you create key information when you install the AppManager repository or manually using the NQKeyGenWindows utility. If you have an existing key file generated by the NetIQ Encryption utility (rpckey.exe) in a previous release, you can continue to use that key file and distribute it to AppManager 7.x agents, if needed, until you are ready to replace the old key file with one generated with the NQKeyGenWindows utility.

After you distribute an updated key file to all of the Windows agents, including the agent on the management server computers within your site in your site, you will experience a temporary loss of communication between the management server and the agents. To have the management server receive the new security key information from the repository database and resume communication with the updated Windows agents, you must stop and restart the NetIQ AppManager Management Service (`NetIQms`).

NOTE: If you already distributed an AppManager 7.x key file to your Windows agents, you can use the same key file for both Encrypted and Encrypted and Authenticated communication. You do not need to re-key your Windows agents to change the security level for those agents.

For more information, see "Using Secure Communication for Windows Agents" and "Key File Utility for Windows Agents" in the *Administrator Guide for AppManager*. For more information about configuring security after an AppManager upgrade, see the *Upgrade and Migration Guide for AppManager*.

7.2.1 Resource Objects

Windows 2000 Server or later

7.2.2 Default Schedule

The default interval for this script is **Run once**.

7.2.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It

Location of key file	Provide the full path to the agent key file. For example:
	`C:\temp\nqWindowsPublic0.key`
	To specify some other computer in the environment rather than the target computer, type the UNC path to the file. For example, if the key is stored in the `E:\Temp` folder on the computer `zebra`:
	`\\zebra\e$\temp\nqWindowsPublic0.key`

Encryption password	Provide the password you specified when you created the agent key file. The characters that you type appear as asterisks to protect your password.
Raise event if the update succeeds?	Select **y** to raise an event when the key is successfully updated on the target computer. The default is y.
Event severity when the update succeeds	Set the event severity level, from 1 to 40, to indicate the importance of a successful registration of the management server. The default severity level is 25 (blue event indicator).

7.3 AgentConfigSecurityLevel

Use this Knowledge Script to remotely update the agent security level on the managed Windows computers in your site. When configuring the security level for the agent, keep in mind that all managed Windows clients and management server computers in an AppManager site must be configured to use the same security level. For more information about implementing AppManager secure communication, see the *Administrator Guide for AppManager*.

Use this script to change the security level on the managed Windows clients in your AppManager site either before or after you change the security level on the repository database. The new security level takes effect on the agent as soon as the script completes.

If your repository database is configured to use Encryption or Encryption and Authentication, and you change the security level on the agent to Cleartext, this script will not immediately raise a successful event. In this case, the agent cannot communicate with the management server until you change the security level on the repository database and restart the management server.

The following security levels are available:

- **0 - Cleartext – no security** indicates that all communication between the agent and the management server is in cleartext and is not encrypted. This option is available for all supported versions of the AppManager agent.
- **1 - Encryption – medium security** indicates that all communication between the agent and the management server is encrypted but the agent does not authenticate the identity of the management server. This option is available for all supported versions of the AppManager agent.
- **2 - Encryption and authentication – highest security** indicates that the agent will attempt to authenticate the identity of the management server before sending and receiving encrypted communication. This option is available for version 7.0 (or later) of the AppManager agent.

To use the AgentConfigSecurityLevel script to increase the security level on your Windows agents (for example, from Cleartext to Encryption and Authentication):

1. Use the `NQKeyGenWindows.exe` utility to generate an encryption key file and insert it into the repository database. You can find this utility in the `Program Files\NetIQ\AppManager\bin` directory.

   NOTE: The same key file can be used for both encrypted and encrypted and authenticated communication.

2. If you have not done so already, use the AgentConfigSecurityKey script to distribute the agent portion of the key file to all of your Windows agents, including the agent on the management server computers within your site.
3. Use the `NQKeyGenWindows.exe` utility to change the security level on the repository database.
4. Use the AgentConfigSecurityLevel script to change the security level on the agents, including the agent on the management server computers within your site.
5. Stop and restart the NetIQ AppManager management server service (`NetIQms`) to communicate at the specified security level.

7.3.1 Resource Objects

Windows 2000 Server or later

7.3.2 Default Schedule

The default interval for this script is **Run once**.

7.3.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Security level	Select the security level you want the managed Windows computer to use: • **0 - Clear text** if you want all communication between the agent and the management server to be in clear text and is not encrypted. This option is best for closed network environments, testing, or troubleshooting communication issues. • **1 - Encryption** if you want all communication between the agent and the management server to be encrypted but do not require authentication. • **2 - Encryption and authentication** if you want the management server to be authenticated before sending and receiving encrypted communication. Keep in mind that, for a single repository, all managed Windows clients must use the same security level setting. Any time you update security, you must do so for all of your Windows agents. If you cannot update all of your WIndows agents at once, the management server will not be able to communicate with those agents and the interruption in communication may result in missing critical events or data. Therefore, you should plan any change to the security level carefully to minimize the chance of communication failures. The default is 0 - Clear text.
Raise event when update succeeds?	Select **y** to raise an event when the security level is successfully updated. This script always raises an event if the job does not run successfully. If enabled, you can configure the severity level of the event. The default is y.
Event severity when the update...	Set the event severity level, from 1 to 40, to reflect the importance when the job: • **... succeeds**. If you set this script to raise an event when the job succeeds, set the event severity level for a successful discovery. The default is 25 (blue event indicator). • **... fails**. The default is 5 (red event indicator).

7.4 AgentHealth

Use this Knowledge Script to monitor the status of the AppManager agent, specifically, the Managed Client (MC) and Client Communication Manager (CCM) services. This script looks for self-monitoring events of several types (general, communication, job, security, and upgrade) in the Windows Application log. An event is raised when AppManager places a self-monitoring event in the Windows Application log.

You can filter the event log entries associated with the agent services by specifying a combination of include and exclude strings for each event field. All event log entries that match the filtering criteria are returned in the event detail message.

This script should be run on computers that do not have the Management Server installed. To monitor for self-monitoring events on Management Server computers, use the MSHealth script.

7.4.1 Resource Objects

Windows 2000 Server or later

7.4.2 Default Schedule

The default interval for this script is Asynchronous.

Regardless of the schedule you select, once you start the script, its job status appears as Running.

7.4.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Monitor events of type...	Select **y** to raise an event when AppManager places a self-monitoring event in the Windows Application Log of any of the following types: • **... general**. The default is y. • **... communications**. The default is y. • **... job**. The default is y. • **... security**. The default is y. • **... upgrade**. The default is y.
Event severity for events of type...	Set the event severity level, from 1 to 40, to reflect the importance when the following types of event are inserted in the Windows event log: • **... general**. The default is 15 (yellow event indicator). • **... communications**. The default is 15 (yellow event indicator). • **... job**. The default is 15 (yellow event indicator). • **... security**. The default is 15 (yellow event indicator). • **... upgrade**. The default is 15 (yellow event indicator).

Parameter	How to Set It
Filter events by event description	If you set a filter here, the script looks for matching entries in the event log's **Description** field. Multiple strings can be entered, separated by commas. The filter string can contain criteria used to include entries, exclude entries, or both. Separate the include and exclude criteria with a colon (:). If you are specifying only include criteria, the colon is not necessary. For example: communication,cold start:mc,ccm
Use case-sensitive description filter?	Select **y** to make all filter statements for this script case-sensitive. The default value is n (not case-sensitive).

7.5 AgentSelfMon

Use this Knowledge Script to monitor the health of the scripting engine in the AppManager agent on a Windows computer. In some cases, the scripting engine does not run jobs properly but the AppManager agent may respond to remote procedure calls from AppManager diagnostic utilities. In this case, restarting the AppManager agent and the scripting engine resolves the problem. This script is not applicable on UNIX computers.

This script monitors the health of the scripting engine on the agent by running a job that updates a timestamp value in the Windows registry. If the age of the timestamp value exceeds the threshold you specify, the Client Communication Manager service (`netiqccm.exe`) automatically restarts the AppManager agent service (`netiqmc.exe`).

During the first monitoring interval, the Client Communication Manager service (`netiqccm.exe`) writes the current timestamp value to the Windows registry; subsequent job iterations compare and then update the timestamp value.

The timestamp and threshold values are stored in the registry under `HKEY_LOCAL_MACHINE\SOFTWARE\NetIQ\AppManager\4.0` as follows:

Registry Entry	Registry Location
Timestamp value that is written each time the job runs	NetIQmc\Admin\LastMCCheck
Threshold, in seconds, for the maximum age of timestamp value	NetIQccm\Admin\MCFreezeThreshold

7.5.1 Resource Objects

Windows 2000 Server or later

7.5.2 Default Schedule

The default interval for this script is **Every 5 minutes**.

The interval you select must be less than or equal to the value you specify in the *Threshold - Maximum age of timestamp value* parameter.

7.5.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Threshold –Maximum age of timestamp value	Specify a threshold, in seconds, for the maximum age of the timestamp value. If the elapsed time exceeds the threshold, the Client Communication Manager service (`netiqccm.exe`) automatically restarts the managed client (`netiqmc.exe`). If you specify 0, the current value of the `MCFreezeThreshold` registry key is used. This feature allows you to configure the threshold value a single time. If a value of 0 is specified, the job will not run if the value of `MCFreezeThreshold` is less than the job's scheduled interval. The default value is 0. **NOTE:** If you specify a threshold other than 0, the threshold must be greater than or equal to the scheduled job interval. If the threshold is less than the interval, the job does not run and an event (severity level 40) is raised.

7.6 ChangeFooter

Use this Knowledge Script to change the graphic and hyperlink that appear at the bottom of each report page.

The NetIQ logo is the default graphic and the default hyperlink is to the NetIQ Web site. This script allows you to substitute a different graphic and hyperlink, or to restore those settings to the defaults.

7.6.1 Resource Object

AppManager repository object under the Report agent

7.6.2 Default Schedule

The default interval for this script is **Run once**.

7.6.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if set or restore operation succeeds?	Select **y** to raise an events if the script job succeeds in setting a new report footer or in restoring the default report footer. By default, events are raised.
Set new footer or restore default footer	• Select **Set a new footer** to change the default settings. This option clears the existing values for the *Full path to new picture file*, *Hyperlink text*, and *URL* parameters. • Select **Restore to NetIQ default footer** to restore the default settings. This option restores the default values for the *Full path to new picture file*, *Hyperlink text*, and *URL* parameters.)
Full path to logo image file	Provide the full path to the new picture file you want to use. For example, `C:\LogoFiles\Logo1.gif`.
Hyperlink text	Provide the new text for the hyperlink that appears next to the picture file.
URL for hyperlink	Provide the URL referenced by the hyperlink.
Use actual image size?	Select y to use the actual size of the new footer image. If this parameter is disabled, the image is scaled to the size of the default footer image. The default is y.
Event severity when set or restore operation succeeds	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 35 (magenta level indicator).
Event severity when job fails	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 5 (red event indicator).

7.7 ConcurrentRpt

Use this Knowledge Script to get the setting for the number of concurrent report jobs that can be managed by a report agent, or to reset that registry key to another value. This script queries the registry on a computer where you have installed a report agent to get or set the number of concurrent reports.

7.7.1 Resource Object

AppManager repository object under the Report agent

7.7.2 Default Schedule

The default interval for this script is **Run once**.

7.7.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if query or set operation succeeds?	Select **y** to raise events. The default is y. When you query the registry to get the value for the number of concurrent reports, the event detail message contains the current setting.
Query, or set new value?	Set the value to **query** to query the registry and get the value of the registry key. Set the value to **set** to change the value of the registry key. In order for the value to take effect, you must restart the managed client. If you select **set**, use the *Number of concurrent reports* parameter to define the number of concurrent jobs.
Number of concurrent reports (optional)	Define the number of concurrent report jobs managed by the report agent. The default is 3. **NOTE:** Setting this value too high can overload the report agent, slow the generation of reports, and adversely affect the performance of the report agent computer.
Event severity when query or set operation succeeds	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 35 (magenta level indicator).
Event severity when job fails	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 5 (red level indicator).

7.8 ConfigAdminEvents

Use this Knowledge Script to update event severity settings in the registry: `HKEY_LOCAL_MACHINE\Software\NetIQ\AppManager\4.0`. By using this script, you do not have to manually update severity settings in the registry for the following AppManager agent (`NetIQmc` and `NetIQccm`) and Management Service (`NetIQms`) events:

- Management Service events
  - `NetIQms` administrative alerts updated in the `\netiqms\admin\AdminEvtSev` registry key
  - `NetIQmc` job failures updated in the `netiqms\config\MC Job Abort Event Sev` registry key
  - Orphaned job events updated in the `\netiqms\config\Orphan Job Event Sev` registry key
  - General success events updated in the `\netiqms\admin\General Success Events` registry key
  - General failure events updated in the `\netiqms\admin\General Failure Events` registry key
- AppManager agent events
  - `NetIQmc` administrative alerts updated in the `\netiqmc\admin\AdminEvtSev` registry key
  - Knowledge Script failure events updated in the `\netiqmc\admin\Knowledge Script Failure Events` registry key
  - `NetIQccm` administrative alerts updated in the `\netiqmc\admin\AdminEvtSev` registry key

This script raises events if Management Service and agent event severity settings are applied to the registry, and if the Management Service is not installed on the agent computer.

NOTE:

- For AppManager versions earlier than 8.x, you must restart the `NetIQmc`, `NetIQms`, and `NetIQccm` services after using this Knowledge Script to update the registry. The updated registry settings do not take effect until you restart the services.
- For more information about AppManager registry settings, see the *Administrator Guide for AppManager*, available on theNetIQ AppManager Documentation Web site.

7.8.1 Prerequisite

AppManager version 8.x or later is required to support registry updates for the following events. The registry keys for these events are not created in earlier versions of AppManager.

- General success events
- General failure events
- Knowledge Script failure events

7.8.2 Resource Objects

Windows 2000 Server or later

7.8.3 Default Schedule

By default, this script runs once.

7.8.4 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Job Failure Notification	
Event severity when job fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the ConfigAdminEvents job fails. The default is 5.
Apply Management Service severity settings to registry?	Select **Yes** to update the severity settings for the following Management Service events: • Administrative alerts • `NetIQmc` job failures • Orphaned job events • General success events • General failure events The default is Yes.
Event severity for administrative alerts	Set the severity level, from 1 to 40, to indicate the importance of an event in which administrative alerts for the Management Service occur. The default is 40.
Event severity for NetIQmc job failures	Set the severity level, from 1 to 40, to indicate the importance of an event in which the NetIQmc job fails. The default is 10.
Event severity for orphaned job events	Set the severity level, from 1 to 40, to indicate the importance of an event in which job events are orphaned. The default is 5.
Event severity for general success events (AppManager 8 and later)	Set the severity level, from 1 to 40, to indicate the importance of an event in which sgeneral success events occur. The default is 35. **NOTE:** This parameter is not supported for versions of AppManager earlier than version 8.x.
Event severity for general failure events (AppManager 8 and later)	Set the severity level, from 1 to 40, to indicate the importance of an event in which general failure events occur. The default is 5. **NOTE:** This parameter is not supported for versions of AppManager earlier than version 8.x.
Apply agent severity settings to registry?	Select **Yes** to update the registry with severity settings for the following agent events: • NetIQmc administrative alerts • Knowledge Script failures • NetIQccm administrative alerts The default is Yes.
Management Client (NetIQmc)	
Event severity for administrative alerts	Set the severity level, from 1 to 40, to indicate the importance of an event in which NetIQmc administrative alerts occur. The default is 40.

Parameter	How to Set It
Event severity for Knowledge Script failures (AppManager 8 and later)	Set the severity level, from 1 to 40, to indicate the importance of an event in which the Knowledge Script fails. The default is 5. **NOTE:** This parameter is not supported for versions of AppManager earlier than version 8.x.
Suppress events with severity equal to	Use this parameter to ignore NetIQmc events with a severity equal to the value you provide. The default is a severity level of 0.
Client Communication Manager (NetIQccm)	
Event severity for administrative alerts	Set the severity level, from 1 to 40, to indicate the importance of an event in which NetIQccm administrative alerts occur.The default is 40.
Event Notification	
Raise event if Management Service severity settings successfully applied to registry?	Select **Yes** to raise an event if Management Service severity settings are applied to the registry successfully. The default is Yes.
Event severity when settings successfully applied to registry	Set the severity level, from 1 to 40, to indicate the importance of an event in which Management Service severity settings are applied to the registry successfully. The default is 16.
Raise event if Management Service not installed on agent computer?	Select **Yes** to raise an event if the Management Service is not installed on the agent computer on which you run this script. The default is Yes.
Event severity when Management service not installed on agent computer	Set the severity level, from 1 to 40, to indicate the importance of an event in which the Management Service is not installed on the agent computer on which you run this script. The default is 25.
Raise event if agent severity settings successfully applied to registry?	Select **Yes** to raise an event if AppManager agent severity settings are applied to the registry successfully. The default is Yes.
Event severity when settings successfully applied to registry	Set the severity level, from 1 to 40, to indicate the importance of an event in which AppManager agent severity settings are applied to the registry successfully. The default is 16.

7.9 ConfigSiteCommType

Use this Knowledge Script to configure the AppManager Client Communication Manager service, `NetIQccm`, to use an IP address or hostname to communicate with the management server.

By default, the Client Communication Manager service uses an IP address to locate and communicate with the management server. However, in some environments this may present problems. For example, if your management server and managed clients are connected through a remote dialup connection and use DHCP, IP addresses may be assigned dynamically and change from one connection time to the next, or your management server may be installed on a cluster requiring you to use a cluster name rather than a specific IP address. Use this script to change the default setting for the CCM service.

Configuring AppManager services to use an IP address or hostname is done on a site-by-site basis.

7.9.1 Resource Objects

Windows 2000 Server or later

7.9.2 Default Schedule

The default interval for this script is **Run once**.

7.9.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Use IP address to communicate with management server?	Select **y** to have the `NetIQccm` service use an IP address to establish communication with the management server. Select **n** to have the `NetIQccm` service connect to the management server using a hostname. The default is y.
Raise event if communication configuration succeeds?	Select **y** to raise an event indicating the success of the operation. The default is n.
Event severity when job...	Set the event severity level, from 1 to 40, to reflect the importance of the event when the attempt to set the method used by the agent service to communicate with the management server: **... succeeds**. If you set this script to raise an event when the job succeeds, set the event severity level for a successful discovery. The default is 25 (blue event indicator). **... fails**. The default is 5 (red event indicator).

7.10 ConfigSiteNetFlowCtrl

Use this Knowledge Script to configure the characteristics of NetIQ Corporation AppManager Client Communication Manager service (`NetIQccm`) communication to the management server for the current repository.

This script allows you to control the flow of network traffic from a managed client to the management server by defining upper and lower bandwidth limits for the size of message batches transferred. One batch is sent at each communication interval. You can also set the length of the communication interval in seconds.

7.10.1 Resource Objects

Windows 2000 Server or later

7.10.2 Default Schedule

The default interval for this script is **Run once**.

7.10.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Network flow upper limit	Specify an upper bandwidth limit, in KB, for each network message batch from NetIQccm to the management server. The default of 0 indicates no upper limit.
Network flow lower limit	Specify a minimum bandwidth, in KB, for each network message batch from NetIQ Corporationccm to the management server. The default of 0 indicates no lower limit.
Communication interval	Specify the frequency (in seconds) with which NetIQccm can send message batches to the management server. The default is 0 indicates no delay between message batches.
Tune network flow dynamically?	Select **y** to have the `NetIQccm` agent service dynamically tune and control the size of network message flows to the management server, based on the management server's current load. The default is n.
Raise event if job succeeds?	Select **y** to raise an event indicating the success or failure of the operation. The default is n.
Event severity when job...	Set the event severity level, from 1 to 40, to reflect the importance when the job: **... succeeds**. If you set this script to raise an event when the job succeeds, set the event severity level for a successful discovery. The default is 25 (blue event indicator). **... fails**. The default is 5 (red event indicator).

7.10.4 Example of How this Script Is Used

This script is intended to help you manage network bandwidth and control and tune the transfer of data from managed clients to the management server to suit your network capacity. Using this script, you can restrict the amount of data the `NetIQccm` agent service sends at any one time, as well as the frequency of data transfers.

For example, assume you define an upper limit of 100K, a lower limit of 2K, and a communication interval of one hour (3600 seconds). With this configuration, `NetIQccm` sends up to 100K of data per hour to the management server until the data waiting to be transferred falls below 2K. `NetIQccm` then stores the data in the local repository. At the next interval, if the data to be transferred is greater than 2K, `NetIQccm` resumes sending the data to the management server. If the data package is still below 2K, `NetIQccm` continues to store the data in the local repository until the next interval.

"Dynamic tuning" provides additional flexibility by allowing `NetIQccm` to respond to load changes on the management server. When the *Tune network flow dynamically?* parameter is enabled and the management server becomes busy, `NetIQccm` decreases the amount of data sent and increases the communication interval until the load on the management server is reduced.

Each time the `NetIQccm` service connects to transfer data, it checks the current load on the management server. If load has increased, `NetIQccm` further reduces the amount of data sent in each batch. `NetIQccm` continues to reduce the amount of data sent until the amount of data to be sent falls below the lower limit you set, or until load on the management server decreases, freeing up bandwidth.

7.11 DBHealth

Use this Knowledge Script to monitor SQL Server resources associated with the AppManager repository, including:

- The percentage of database space and log space used.
- The time it takes a SQL command or query to execute.
- The status of AppManager scheduled tasks (SQL Server Agent jobs that operate on the AppManager repository).

You can set a threshold for each database resource monitored. If any threshold is exceeded, an event is raised. In addition, you can use this script to check whether any SQL Server services are stopped, and whether AppManager scheduled tasks have failed to run or have been disabled. You can optionally restart services and re-enable scheduled tasks.

This script requires the SQL Server system administrator (`sa`) account or an account with `sa` privileges to run.

If you implement any responsive actions in conjunction with this script, you should set the Location of the actions to **MC**, so they run as managed client actions and are executed even if the management server is not connected to the AppManager repository.

7.11.1 Resource Object

SQL Server where the AppManager repository is installed.

7.11.2 Default Schedule

The default interval for this script is **Every 10 minutes**.

This script checks the `sysjobschedules` table in the `msdb` database to determine the last execution time of each SQL Server Agent job that operates on the AppManager repository. The `sysjobschedules` table is updated at 20-minute intervals, and so running this script at more frequent intervals does not yield more timely information about the failure of SQL Server Agent jobs.

7.11.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Event Notification	
Raise event if SQL services are down?	Select **Yes** to raise an event if any SQL Server services are detected as down. The default is Yes. **NOTE:** If SQL Server services are not running, the other elements of database health cannot be monitored and the associated events cannot be raised.
Event severity when a service is down	Set the severity level, from 1 to 40, to indicate the importance of the event. The default is 5 (red event indicator).

Parameter	How to Set It
Raise event if service was shut down normally?	Select **Yes** to raise an event when a service is stopped in a normal manner (for example, by a user or as the expected result of another service being stopped). The default is Yes.
Event severity when service was shut down normally	Set the severity level, from 1 to 40, to indicate the importance of the event. The default is 30 (blue event indicator).
Raise event if service is started?	Select Yes to raise an event if the script successfully restarts a stopped service. The default is unchecked. Note This parameter is effective only when the *Start Down Services* parameter is also Select Yes.
Event severity when attempt to start service fails	Set the severity level, from 1 to 40, to indicate the importance of the event. The default is 10 (red event indicator).
Event severity when service started	Set the severity level, from 1 to 40, to indicate the importance to the event. The default is 25 (blue event indicator).
Raise event if service is missing?	Select **Yes** to raise an event when a SQL Server service is not installed in the computer. The default is unselected.
Event severity when service is missing	Set the severity level, from 1 to 40, to indicate the importance of the event. The default is 8 (red event indicator).
Raise event if service is disabled?	Select **Yes** to raise an event when a SQL Server service is disabled. The default is unselected.
Event severity when service is disabled	Set the severity level, from 1 to 40, to indicate the importance of the event. The default is 12 (yellow event indicator).
Raise event if database space usage exceeds threshold?	Select **Yes** to raise an event when the *Maximum used database space* threshold has been exceeded. The default is unselected.
Event severity when database space usage exceeds threshold	Set the severity level, from 1 to 40, to indicate the importance of the event. The default is 5 (red event indicator).
Raise event if log space usage exceeds threshold?	Select **Yes** to raise an event when the Log space utilization threshold has been exceeded. The default is Yes.
Event severity when log space usage exceeds threshold	Set the severity level, from 1 to 40, to indicate the importance of the event. The default is 5 (red event indicator).
Raise event if management server not connected?	Select **Yes** to raise an event if the AppManager management server is not connected to the AppManager repository. The default is Yes.
Event severity when management server not connected	Set the severity level, from 1 to 40, to indicate the importance of the event. The default is 5 (red event indicator).
Raise event if AppManager SQL jobs disabled?	Select **Yes** to raise an event when any SQL Server Agent job that operates on the AppManager repository has been disabled. The default is Yes.
Raise event if attempt to enable SQL job succeeds?	Select **Yes** to raise an event when a disabled SQL Server Agent job that operates on the AppManager repository is successfully enabled. The default is unchecked.

Parameter	How to Set It
Event severity when attempt to enable SQL job fails	Set the severity level, from 1 to 40, to indicate the importance of the event. The default is 5 (red event indicator).
Event severity when attempt to enable SQL job succeeds	Set the severity level, from 1 to 40, to indicate the importance of the event. The default is 5 (red event indicator).
Raise event if AppManager SQL jobs are not running as scheduled?	Select **Yes** to raise an event when a SQL Server Agent job that operates on the AppManager repository does not run as scheduled. The default is Yes.
Event severity when attempt to retrieve SQL job status fails	Set the severity level, from 1 to 40, to indicate the importance of the event. The default is 5 (red event indicator).
Event severity when SQL job fails to run	Set the severity level, from 1 to 40, to indicate the importance of the event. The default is 5 (red event indicator).
Raise event if query process time exceeds threshold?	Select **Yes** to raise an event when the run time for a SQL Server command or query exceed the *process run time threshold*. The default is Yes.
Event severity when query process time exceeds threshold	Set the severity level, from 1 to 40, to indicate the importance of the event. The default is 10 (red event indicator).
Event severity when attempt to retrieve query process time fails	Set the severity level, from 1 to 40, to indicate the importance of the event. The default is 10 (red event indicator).
Raise event if AppManager repository not found?	Select **Yes** to raise an event if no AppManager repository can be located on the SQL Server on which the script is running. The default is unselected.
Event severity when AppManager repository not found	Set the severity level, from 1 to 40, to indicate the importance of the event. The default is 20 (yellow event indicator).
Event severity when job fails	Set the severity level, from 1 to 40, to indicate the importance of the event raised when the script fails to run properly. The default is 5 (red event indicator).
Data Collection	
Collect data for database space utilization?	Select **Yes** to collect data for charts and reports. If enabled, returns the percentage of used database space. The default is unselected.
Collect data for log space utilization?	Select **Yes** to collect data for charts and reports. If enabled, returns the percentage of used log space. The default is unselected.
Collect data for management server connection status?	Select **Yes** to collect data for charts and reports. If enabled, returns the status of the management server connection to the AppManager repository. Returns either: **100** – management server is connected; or **0** – management server is not connected. The default is unselected.

Parameter	How to Set It
Collect data for service status?	Select **Yes** to collect data regarding the up/down status of SQL Server services. The values returned are set in the following parameters: Data value - Service up Data value - Service down The default is unselected.
Collect data for dependent services?	Select **Yes** to also collect data for any services that are dependent on the monitored SQL Server services. The default is unselected.
Monitoring	
SQL username	Specify the database user login account that you want to use to access SQL Server. This script requires the "`sa`" account or an account that has `admin` group privileges on the target SQL Server. If you want to use a login account other than `sa`, use the AppManager Security Manager to identify the account. The default is `sa`. **NOTE:** If you are monitoring SQL Server 7, you need to use a `sysadmin` role account.
Threshold – Maximum database space utilization	Specify a threshold for the maximum percentage of database space that can be used before an event is raised. The default is 90%.
Threshold – Maximum log space utilization	Specify a threshold for the maximum percentage of log space that can be used before an event is raised. The default is 80%.
Enable disabled SQL jobs?	Select **Yes** to enable SQL Server Agent jobs that have been disabled. The default is Yes.
Threshold – Maximum process run time	Specify the maximum number of seconds allowed for process run time (the time it takes a SQL command or query to complete) before an event is raised. The default is 30 seconds.
Start services if down?	Select **Yes** to start any SQL Server service that is stopped. The default is Yes.
Start dependent services?	Select **Yes** to also start any services that are dependent on SQL Server services started by the script. The default is Yes.
Restart service if shut down normally?	Select **Yes** to start services that were shut down under normal circumstances (for example, by a user or as the expected result of another service being stopped). The default is Yes.
Service start timeout	Specify the number of seconds the script should attempt to start a down service before timing out. The default is 30 seconds.

7.11.4 Example of How this Script Is Used

This script enables you to monitor the AppManager repository for conditions that may cause abnormal operation or result in database consistency problems. This script also helps you monitor the growth and sizing requirements for the AppManager repository so you can plan for changes to your database configuration or your site configuration.

For example, as you monitor more servers and more applications in your environment, or as you gather more data and generate more events, this script monitors the repository to be sure you have the resources to accommodate the increase. If you find you are exceeding any threshold, it may indicate that you should change your database configuration options, for example, to increase the maximum number of user connections or the size of `tempdb`.

If you continue to see events or see the events indicate heavy work load (for example, longer query execution times), you may need to consider splitting your site by installing additional management servers and repositories or freeing up space on your repository server by moving the AppManager management server and repository components onto separate computers.

7.12 DeleteExpiredReports

Use this Knowledge Script to delete expired reports generated by an AppManager report agent. If you have configured more than one report agent to generate reports to the same location, run this script on one of the report agents to delete all expired reports.

7.12.1 Resource Object

Report agent

7.12.2 Default Schedule

The default interval for this script is **Run once**.

You can set the schedule to periodically check for expired reports.

7.12.3 Setting Parameter Values

Set the following parameters as needed:

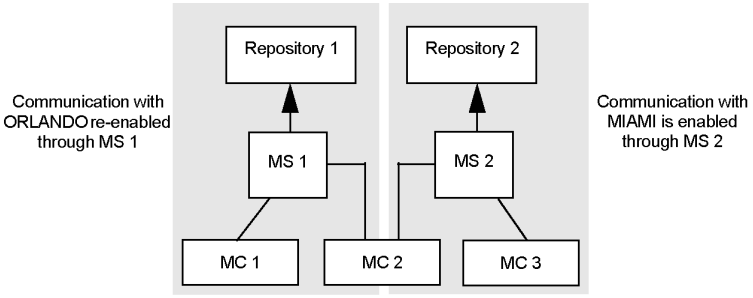
Parameter	How to Set It
Raise event if report successfully deleted?	Select **y** to raise an event if expired reports are deleted. The default is y.
Generate deletion report?	Select **y** to generate a report detailing which reports were deleted. The default is y.
Include parameter table?	Select **y** to include a table in the report that lists parameter settings for the Report script. The default is y.
Select output folder	Set parameters for the output folder. The default folder name is DeleteExpRpts.
Add job ID to output folder name?	Select **y** to append the job ID to the name of the output folder. The default is n. The job ID helps you correlate a specific instance of a Report script with the corresponding report.
Select properties	Provide a name for the report and set any other report parameters. The default report name is Expired Reports Deleted.
Add timestamp to title?	Select **y** to append a timestamp to the title of the report, making each title unique. The default is n. A timestamp allows you to run consecutive iterations of the same report without overwriting previous output.
Event severity when report successfully generated	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 35 (magenta level indicator).
Event severity when report has no data	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25 (blue level indicator).
Event severity when report generation fails	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 5 (red level indicator).

7.13 DisableSiteComm

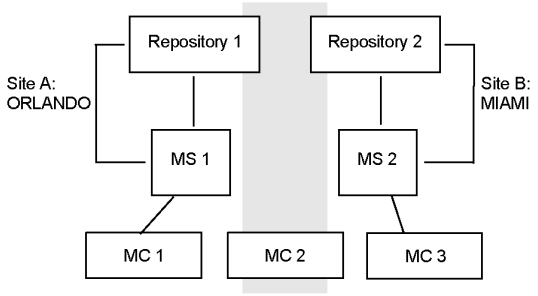
Use this Knowledge Script to temporarily disable network communication from a managed client on Windows to the repository. All messages, including events, data, and job status, are saved in the local repository of the managed client until network communication is re-enabled, at which point it is transferred to the management server. The size of message batches and frequency of delivery can be controlled through the ConfigSiteNetFlowCtrl script.

If a managed client is managed by more than one site (that is, if information for the managed client is stored in more than one repository) you can set *Disable communications for all sites* to **y** to disable communication from the managed client to all repositories with which the managed client communicates.

In this simplified example, MC 2 normally sends data and events to both `ORLANDO` and `MIAMI`.

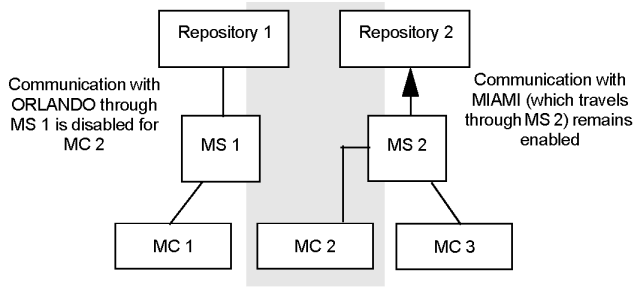


If you run this script on MC 2 and enable the *Disable communications for all sites* parameter, communication to both `ORLANDO` (Repository 1) and `MIAMI` (Repository 2) is disabled for MC 2. Communications by MC 1 and MC 3 are not affected.



You can set the *Disable communications for all sites* parameter to **n** to disable communication from the managed client only to the repository you are currently logged onto.

For example, you have logged onto Repository 1 in AppManager (in the Login dialog box). You run this script on MC 2 and set *Disable communications for all sites* to **n**. Communication between MC 2 and Repository 1 is disabled, but communication between MC 2 and Repository 2 is unaffected. Communications by MC 1 and MC 3 are also unaffected.



7.13.1 Resource Objects

Windows 2000 Server or later

7.13.2 Default Schedule

The default interval for this script is **Run once**.

7.13.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Disable communications for all sites?	Select **y** to disable communication between the managed client and the repositories with which it communicates. Select **n** to disable communication from the managed client to the repository you are logged onto. The default is n.
Raise event when attempt to disable communication succeeds?	Select **y** to raise an event indicating the success of the operation. An event is always raised when the job fails. The default is n.
Event severity when attempt to disable communication...	Set the event severity level, from 1 to 40, to reflect the importance when the job: **... succeeds**. If you set this script to raise an event when the job succeeds, set the event severity level for a successful discovery. The default is 25 (blue event indicator). **... fails**. The default is 5 (red event indicator).

7.13.4 Example of How this Script Is Used

This script lets you intentionally stop the communication between managed clients and repositories. For example, if you are experiencing network problems, you may want to temporarily disable communication while you troubleshoot the problem.

You can also force data and events be stored in the local repository. For example, if you are experiencing high network activity, you can disable communication between the managed client and the management

server and store data locally until the demand for server bandwidth is reduced. To set up a regular schedule for uploading events or data from the local repository, use the SiteSchedUpload script.

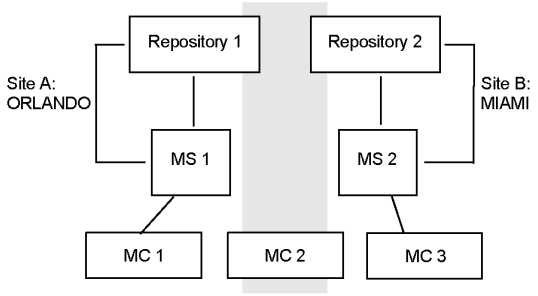
7.14 EnableSiteComm

Use this Knowledge Script to resume regular ongoing network communication from a managed client to the management server. Network communication may be disabled because you have run the DisableSiteComm script to disable network communication between the managed client and management server.

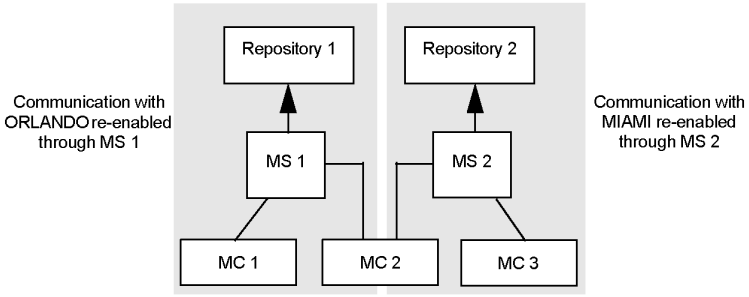
As soon as network communication is restored, any information temporarily stored in the local repository of the managed client while communication was disabled is transferred to the management server, either immediately or in the next scheduled upload if the managed client is configured to transfer events or data according to a schedule.

If a managed client is managed by more than one site (that is, if information for the managed client is stored in more than one repository) you can set the *Enable communications for all sites* parameter to y to enable communication from the managed client to all management sites with which the managed client communicates.

In this simplified example, MC 2 normally sends data and events to both `ORLANDO` and `MIAMI`, but communication with these sites has been temporarily disabled for this managed client.

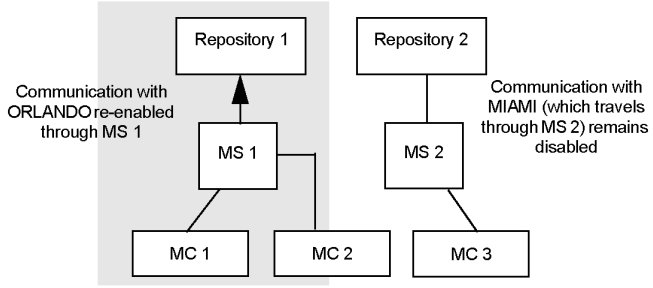


If you run this script on MC 2 and enable the *Enable communications for all sites* parameter, communication to both `ORLANDO` (Repository 1) and `MIAMI` (Repository 2) is re-enabled for MC 2.



You can set *Enable communications for all sites* to n to enable communication from the managed client only for the repository you are currently logged onto.

For example, if you have logged onto Repository 1 in AppManager (in the Login dialog box), and run this script on MC 2 with *Enable communications for all sites* Select **n**, communication between MC 2 and Repository 1 is enabled, but communication between MC 2 and Repository 2 remains disabled.



7.14.1 Resource Objects

Windows 2000 Server or later

7.14.2 Default Schedule

The default interval for this script is **Run once**.

7.14.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Enable communications for all sites?	Select **y** to enable communication from the managed client to all repositories the managed client communicates with Select **n** to enable communication from the managed client to the repository you are logged onto. The default is n.
Raise event when attempt to enable communication succeeds?	Select **y** to generate an event indicating the success or failure of the operation. The default is n.
Event severity when attempt to enable communication succeeds	Set the event severity level, from 1 to 40, to reflect the importance when the communication succeeds. The default is 25.
Event severity when attempt to enable communication fail	Set the event severity level, from 1 to 40, to reflect the importance when the job fails. The default is 5.

7.15 GreyMachines

Use this Knowledge Script to monitor AppManager agents that have gone "grey," or in other words, agents that are not responding to management server Ping requests. This script raises an event if the number of unresponsive agents exceeds the threshold you set.

7.15.1 Resource Object

SQL Server folder

7.15.2 Default Schedule

The default interval for this script is **Every 5 minutes**.

7.15.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Event Notification	
Raise event if agents are not responding?	Select **Yes** to raise an event when agents have gone "grey" and do not respond to a Ping from the management server. The default is Yes.
Event severity when agents are not responding	Set the severity level, from 1 to 40, to indicate the importance of the event. The default is 5.
Raise event if repository is offline or unavailable?	Select **Yes** to raise an event when repository is offline or unavailable. The default is Yes.
Event severity when repository is offline or unavailable	Set the severity level, from 1 to 40, to indicate the importance of the event raised when the repository is offline or unavailable. The default is 10.
Event severity when GreyMachines job fails unexpectedly	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the Alarms job fails. The default is 5.
Raise individual events for agents that are not responding?	Select **Yes** to raise an event for each agent that is not responding. The default is unselected.
Data Collection	
Collect data for agents that are not responding?	Select **Yes** to collect data for charts and reports. When enabled, data collection returns the number of agents that do not respond to a Ping from the management server. The default is unselected.
Monitoring	

Parameter	How to Set It
SQL user name	Provide the user name for the SQL Server account to use to connect to the AppManager repository. If you leave this parameter blank, the script uses the account under which the `NetIQ AppManager Client Resource Monitor` service is running. The default is `sa`. **NOTE:** The password for a SQL Server account must be stored in the AppManager repository. Use AppManager Security Manager to enter SQL Server security information into the AppManager repository.
AppManager repository name	Provide the name of the AppManager repository you want to monitor for unresponsive agents. The default is `QDB`.
Threshold – Maximum number of agents that are not responding	Set a threshold for the maximum number of unresponsive agents allowed before an event is raised. The default is 0 nonresponsive agents.
SQL Server connection timeout	Set an amount of time, in seconds, that the script should wait to get a response from the AppManager repository server when attempting to retrieve the list of “grey” (unresponsive) agents before timing out. The default is 10 seconds.
SQL Server connection retry attempts	Set the number of times the script should retry the attempt to connect to the AppManager repository after a connection timeout occurs. The default is 3 attempts.

7.16 IISContinueSite

Use this Knowledge Script to continue a paused IIS site remotely. If the script is unable to continue a paused IIS site, an event is raised.

This script is not supported on IIS version 7.x.

7.16.1 Resource Objects

Servers running Windows Server 2003 or Windows XP Professional

7.16.2 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Event Notification	
Raise event if operation succeeds?	Select **Yes** to raise an event if the attempt to continue the site succeeds. The default is Yes.
Event severity if operation succeeds	Set the severity level, from 1 to 40, to indicate the importance of the event. The default is 25 (blue event indicator).
Raise event if operation fails?	Select **Yes** to raise an event if the attempt to continue the site fails. The default is Yes.
Event severity if operation fails	Set the severity level, from 1 to 40, to indicate the importance of the event. The default is 15 (yellow event indicator).
Event severity for unexpected error	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 35 (magenta level indicator). This script raises an event for unexpected script errors. For example, if a script aborts before the job starts or during the job, an event is raised.

7.17 IISPauseSite

Use this Knowledge Script to temporarily pause an IIS site. If the IIS site cannot be paused, an event is raised. This script raises an event if the script is unable to continue a paused IIS site.

This script is not supported on IIS version 7.x.

7.17.1 Resource Objects

Servers running Windows Server 2003 or Windows XP Professional

7.17.2 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Event Notification	
Raise event if operation succeeds?	Select **Yes** to raise an event if the attempt to pause the site succeeds. The default is Yes.
Event severity if operation succeeds	Set the severity level, from 1 to 40, to indicate the importance of the event. The default is 25 (blue event indicator).
Raise event if operation fails?	Select **Yes** to raise an event if the attempt to pause the site fails. The default is Yes.
Event severity if operation fails	Set the severity level, from 1 to 40, to indicate the importance of the event. The default is 15 (yellow event indicator).
Event severity for unexpected error	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 35 (magenta level indicator). This script raises an event for unexpected script errors. For example, if a script aborts before the job starts or during the job, an event is raised.

7.18 IISRestartServer

Use this Knowledge Script to stop and then restart an IIS server. This script raises events if the attempt to stop or restart a service fails or succeeds. You can detect and start any service that was stopped abruptly.

7.18.1 Resource Objects

Windows 2000 Server or later

7.18.2 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Event Notification	
Raise event if attempt to restart server succeeds?	Select **Yes** to raise an event if the attempt to restart the IIS server succeeds. The default is Yes.
Event severity if operation succeeds	Set the severity level, from 1 to 40, to indicate the importance of the event. The default is 25 (blue event indicator).
Raise event if attempt to restart server fails?	Select **Yes** to raise an event if the attempt to restart the IIS server fails. The default is Yes.
Event severity if server start fails	Set the severity level, from 1 to 40, to indicate the importance of the event. This Knowledge script raises this event when the attempt to start the IIS server fails. The default is 5 (red event indicator).
Event severity if server stop fails	Set the severity level, from 1 to 40, to indicate the importance of the event. This Knowledge script raises this event when the attempt to stop the IIS server fails. The default is 5 (red event indicator).
Event severity for unexpected error	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 35 (magenta level indicator). This script raises an event for unexpected script errors. For example, if a script aborts before the job starts or during the job, an event is raised.
Administration	
Restart the server?	Select **Yes** to restart the IIS server, after it is stopped. The default is Yes.
Service start/stop delay	Set the number of seconds to wait after the IIS server is stopped before attempting to automatically restart it. The default waiting time is 30 seconds.
Restart dependent services?	Select **Yes** to restart any services that depend on the server you stopped. The default is Yes.
Service start/stop retry count	Set the number of times to attempt to restart a service after it has stopped. The script attempts to restart a service 3 times (default).

7.19 IISRestartSite

Use this Knowledge Script to shut down and restart an IIS site instance. This script raises an event if the IIS site cannot be shut down or restarted.

7.19.1 Resource Objects

Windows 2000 Server or later

7.19.2 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Event Notification	
Raise event if operation succeeds?	Select **Yes** to raise an event if the attempt to restart the IIS site succeeds. The default is Yes.
Event severity if operation succeeds	Set the severity level, from 1 to 40, to indicate the importance of the event. The default is 25 (blue event indicator).
Raise event if operation fails?	Select **Yes** to raise an event if the attempt to restart the IIS site fails. The default is Yes.
Event severity if operation fails	Set the severity level, from 1 to 40, to indicate the importance of the event. The default is 15 (yellow event indicator).
Event severity for unexpected error	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 35 (magenta level indicator). This script raises an event for unexpected script errors. For example, if a script aborts before the job starts or during the job, an event is raised.
Administration	
Restart site after shutdown?	Select **Yes** to restart the site after shutdown. The default is Yes.

7.20 LRReadParameters

Use this Knowledge Script to view local repository (LR) configuration information on a managed client computer. You can specify the LR parameter or parameters you want to view, or view all parameters. This script raises an event each time you run the job, and the event details display the name and value of each parameter.

LR information consists of parameter values that are stored in the local repository. You can use this script in conjunction with AppManager *_Config* scripts (for example, General_ConfigMachineDown, NT_ConfigServiceDown) to read the configuration information written in the local repository by the *_Config* scripts.

LR information can be stored in the local repository by using the LRWriteParameters Knowledge Script.

7.20.1 Resource Objects

Windows 2000 Server or later

7.20.2 Default Schedule

The default interval for this script is **Run once**.

7.20.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Event Notification	
Raise event if LR configuration retrieved successfully?	Select **Yes** to raise an event if the script is successful in accessing the local repository and reading the parameter values. The default is Yes.
Event severity when LR configuration retrieved successfully	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 15 (yellow event indicator).
Event severity when job fails	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 5 (red event indicator). This script raises an event for unexpected script errors. For example, if a script aborts before the job starts or during the job, an event is raised.
Administration	
Retrieve all LR parameters?	Select **Yes** to retrieve all LR information in the AppManager agent's local repository. The default is Yes. If you clear this check box, you must specify the name of the parameter or parameters you want to retrieve. For example, if there are two parameters in the local repository, **name** and **location**, to read the value for **location**, specify **location** in any of the *Parameter#* parameters. This script can read the value of up to 20 specified parameters each time you run the script.

Parameter	How to Set It
Parameter 1 ... 20	Specify the name of the parameter or parameters you want to retrieve. Enter the parameter name without quotes. For example, if there are two parameters in the local repository, **name** and **location**, to read the value for **location**, specify **location** in any of the **Parameter#** parameters. If you clear the *Retrieve all LR parameters?* check box, you must specify the parameter names. This script can read the value of up to 20 specified parameters each time you run the script.

7.21 LRRemoveParameters

Use this Knowledge Script to remove local repository (LR) configuration information from a managed client computer. Specify the parameter or parameters you want to remove, or remove all parameters from the local repository. This script raises an event each time you run the job. The event details display information about the parameters that were removed.

LR information consists of parameter values that are stored in the local repository. You can use this script in conjunction with the AppManager *_Config* scripts (for example, General_ConfigMachineDown, NT_ConfigServiceDown) to remove the configuration information entered by the *_Config* scripts from the local repository.

To view LR information that is stored in the local repository, use the LRReadParameters script.

7.21.1 Resource Objects

Windows 2000 Server or later

7.21.2 Default Schedule

The default interval for this script is **Run once**.

7.21.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Event Notification	
Raise event if parameters deleted successfully?	Select **Yes** to raise an event if the script is successful in removing the parameter values. The default is Yes.
Event severity when parameters deleted successfully	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 15 (yellow event indicator).
Event severity when job fails	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 5 (red event indicator). This script raises an event for unexpected script errors. For example, if a script aborts before the job starts or during the job.
Administration	
Delete entire LR?	Select **Yes** to remove all LR information from the AppManager agent's local repository. The default is unselected. If you select this check box, you must specify the name of the parameter or parameters you want to remove. For example, if there are 2 parameters in the local repository, **name** and **location**, to remove the **location** parameter, specify **location** in any of the *Parameter#* parameters. This script can remove up to 20 specified parameters each time you run the script.

Parameter	How to Set It
Parameter 1 ... 20	Specify the name of the parameter or parameter you want to remove. Enter the parameter name without quotes. For example, if there are 2 parameters in the local repository, **name** and **location**, to remove the **location** parameter, specify **location** in any of the *Parameter#* parameters. If you select the *Delete entire LR?* parameter, you must specify the parameter names. This script can remove up to 20 specified parameters each time you run the script.

7.22 LRWriteParameters

Use this Knowledge Script to store local repository (LR) configuration information in a managed client computer. You can specify a name and value for each parameter you want to store. This script raises an event each time you run the job. The event details display information about the parameters that were set.

LR information consists of parameter values that are stored in the local repository. You can use this script to enter your own information into the local repository for use by custom or customized scripts.

This script contains the same capabilities as AppManager *_Config* scripts, except that you can write any named/value pair to the local repository as opposed to specifically named entries. You can use this script instead of the *_Config* scripts when you use the following named entries (shown with their matching *_Config* scripts):

Named Entry	Knowledge Script
_NQ_PingMachine_MachineList	Client_ConfigPingMachine
_NQ_PingMachine_MachineFile	Client_ConfigPingMachine
_NQ_MachineDown_MachineList	General_ConfigMachineDown
_NQ_MachineDown_MachineFile	General_ConfigMachineDown
_NQ_LogicalDisk_DriveList	NT_ConfigLogicalDisks
_NQ_LogicalDisk_TH_UTIL	NT_ConfigLogicalDisks
_NQ_LogicalDisk_TH_FREE	NT_ConfigLogicalDisks
_NQ_LogicalDisk_TH_XFERS	NT_ConfigLogicalDisks
_NQ_LogicalDisk_TH_READS	NT_ConfigLogicalDisks
_NQ_LogicalDisk_TH_WRITES	NT_ConfigLogicalDisks
_NQ_RemoteService_MachineList	NT_ConfigRemoteServiceDown
_NQ_RemoteService_MachineFile	NT_ConfigRemoteServiceDown
_NQ_RemoteService_ServiceList	NT_ConfigRemoteServiceDown
_NQ_Service_ServiceList	NT_ConfigServiceDown
_NQ_Service_ExcludeList	NT_ConfigServiceDown

To remove LR information from the local repository, use the LRRemoveParameters Knowledge Script.

7.22.1 Resource Objects

Windows 2000 Server or later

7.22.2 Default Schedule

The default interval for this script is **Run once**.

7.22.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Event Notification	
Create event if LR set successfully?	Select **Yes** raise an event if the script is successful in setting local repository configuration information. The default is Yes.
Severity - LR set successfully	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 15 (yellow event indicator).
Severity - Job failure	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 5 (red event indicator). This script raises an event for unexpected script errors. For example, if a script aborts before the job starts or during the job.
Administration	
Overwrite value if it already exists?	Select **Yes** to overwrite a parameter value if it already exists in the AppManager agent's local repository. The default is Yes. **NOTE:** This script is not case-sensitive.
Parameter 1 ... 20	Provide the name and value for each parameter you want to set. Enter the parameter name without quotes. For example, to create a **location** parameter and set it to **San Jose**, under any *Parameter#* parameter, specify **location** in **Name** and **San Jose** in **Value**. If the **location** parameter already exists, by default, the value is overwritten. This script can set up to 20 specified parameters each time you run the script.

7.23 MonitorMSCommunications

Use this Knowledge Script to monitor secure agent communications with the management server.

This script monitors the Windows Application log for events that indicate a mismatch of the encryption key used by the agent (on the monitored computer) and the management server.

This script runs continuously and raises an event when a key mismatch is detected.

NOTE: Run this script on computers where the management server is installed.

7.23.1 Resource Objects

Windows 2000 Server or later

7.23.2 Default Schedule

The default schedule for this script is Asynchronous.

7.23.3 Setting Parameter Values

Set the following parameter as needed:

Parameter	How to Set It
Event severity when key mismatch detected	Set the severity level, from 1 to 40, to indicate the importance of the event. The default is 5 (red event indicator).

7.24 MSHealth

Use this Knowledge Script to monitor for self-monitoring events associated with the managed client, Client Communication Manager agent service, and management server. It looks in the Windows Application log for events of several types: general, communication, job, security, and upgrade.

You can filter event log entries by event type and by specifying a combination of include and exclude strings for each event field. All event log entries that match the filtering criteria are returned in the event detail message. An event is raised anytime AppManager places a self-monitoring event in the Windows Application log.

Run this script on computers where the management server is installed. To check for self-monitoring events on computers that do not have the management server installed, use the AgentHealth script.

7.24.1 Resource Object

Windows 2000 Server or later

7.24.2 Default Schedule

The default interval for this script is Asynchronous.

Regardless of the schedule you select, once you start the script, its job status appears as Running.

7.24.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Monitor events of type...	Select **y** to raise an event when AppManager places a self-monitoring event in the Windows Application Log of any of the following types: **... general**. The default is y. **... communications**. The default is y. **... job**. The default is y. **... security**. The default is y. **... upgrade**. The default is y.
Event severity for events of type...	Set the event severity level, from 1 to 40, to reflect the importance when the following types of event are inserted in the Windows event log: **... general**. The default is 15 (yellow event indicator). **... communications**. The default is 15 (yellow event indicator). **... job**. The default is 15 (yellow event indicator). **... security**. The default is 15 (yellow event indicator). **... upgrade**. The default is 15 (yellow event indicator).

Parameter	How to Set It
Filter events by event description	The script will look for matching entries in the event log Description field. Multiple strings can be entered separated by commas. The filter string can contain criteria used to include entries, exclude entries, or both. Separate the include and exclude criteria with a colon (:). If you are specifying only include criteria, the colon is not necessary. For example, to include “communication” and “cold start” event types but exclude them when associated with the managed client or CCM agent service, type: communication,cold start:mc,ccm
Use case-sensitive description filter?	Select **y** to make all filter statements for this script case-sensitive. The default value is n (not case-sensitive).

7.25 RemovePrimaryMS

Use this Knowledge Script to remove the agent's designated primary and secondary management servers. This script removes the designations for the current site. To remove designations for another site, you must run this script from that site.

For performance reasons, you should always designate an agent's primary management server and if there is one, a secondary management server, within a site. To change the management server designations for an agent, use the SetPrimaryMS script.

This script does not change the authorized list of management servers with which the agent can communicate.

Before using this script, make sure the agent is configured to authorize communication with a management server by running the AgentConfigMSRestrictions Knowledge Script. If the agent is not authorized to communicate with a management server and you remove the agent's management server designations, the client computer cannot communicate with AppManager. To resolve this problem, you must manually edit the registry on the managed client computer to specify an authorized management server list in the `\HKEY_LOCAL_MACHINE\SOFTWARE\NetIQ\4.0\NetIQMC\Security\AllowMS`.

7.25.1 Resource Objects

Windows 2000 Server or later

7.25.2 Default Schedule

The default interval for this script is **Run once**.

7.25.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event when primary and backup management server setting removed?	Select **y** to raise an event when the managed client's primary and secondary (backup) management servers have been successfully removed. An event is always raised if the job fails. The default is n.
Event severity when primary and backup management server setting is removed	Set the event severity level, from 1 to 40, to indicate the importance of the event when the job completes successfully. The default severity level is 25 (blue event indicator).

7.26 SchedMaint

Use this Knowledge Script to specify a period of scheduled maintenance for an application resource (such as WMI) or all resources on a managed client computer on Windows. During the maintenance period, regularly scheduled AppManager jobs for the application resource do not run. You can specify the application resources you want to block by script category, or prevent all jobs from running on a server (for example, because of expected downtime).

This icon,  , indicates that a Windows computer is in maintenance mode, or all application resources on a computer are in scheduled maintenance mode. It indicates that AppManager has temporarily stopped monitoring the computer.

- The icon is displayed next to all resources when all application resources for a computer are in scheduled maintenance mode or when a computer is in machine maintenance mode.
- The icon is displayed next to all resource objects on a computer when a particular application resource is in scheduled maintenance mode. Only jobs for the specified application resource are blocked.

You define the start and end time for the scheduled maintenance period under the **Schedule** properties tab. Jobs resume running on the managed computer when the maintenance period expires.

7.26.1 Resource Objects

Windows 2000 Server or later

7.26.2 Default Schedule

The default interval for this script is **Daily**. However, you should use the Schedule tab to set a schedule appropriate to your environment and maintenance needs.

7.26.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Knowledge Script category to block (e.g., SQL)	Specify the script category for the jobs you do not want to run during a maintenance period (for example: sql). You can specify either a single category or an asterisk (*) for all jobs. The default is all jobs (*).
Raise event when schedule implementation succeeds?	Select **y** to generate an event indicating the success or failure of the operation. The default is n.
Event severity when schedule implementation succeeds	Set the event severity level, from 1 to 40, to indicate the importance of a successful registration of the management server. The default severity level is 25 (blue event indicator).

7.26.4 Example of How this Script Is Used

In many environments, specific application servers have regularly scheduled periods when they are brought down by administrators so administrative tasks can be performed.

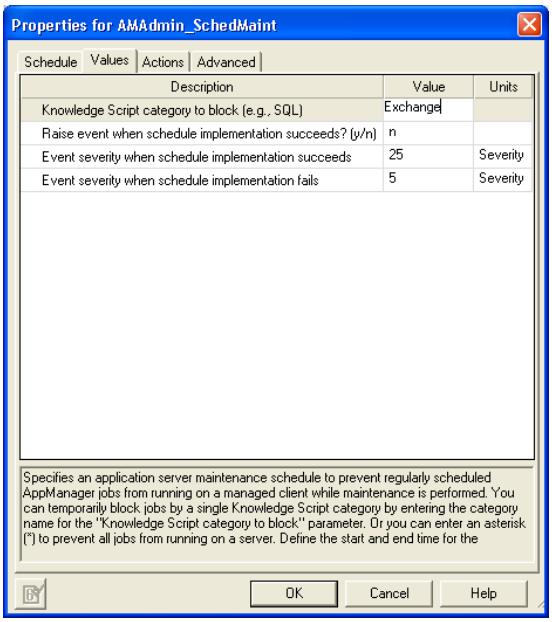
For example, an organization may have 20 Exchange servers that are shut down every Friday at 9 P.M. This interruption causes all of the AppManager Exchange jobs that are not explicitly stopped to error out and forces the administrator to restart the jobs manually when the servers are brought back online.

With this script, administrators can define a specific schedule for temporarily blocking jobs during a planned maintenance period.

Using the Exchange example above, you might set a start time of 8:55 p.m. and an end time of 2:55 a.m. on the Schedule tab. Click **Every** in the Frequency section to set an **End** time. The frequency interval (such as 5 Minutes) is ignored.

On the Values tab, you might identify **exch** (if only Exchange is going to be off-line) or * (if the computers are going to be physically shut down) as the script category to block on the Values tab.

For example, to block Exchange Knowledge Script jobs, you might set the parameters on the Values tab similar to the following example:



At 8:55 p.m. local time (where the job is running), all Exchange Knowledge Script jobs running on the target computers are stopped. At 2:55 a.m. local time, the maintenance period expires and the Exchange jobs resume running at their regularly scheduled intervals.

7.27 SetAllowMS

Use this Knowledge Script in sites with multiple management servers or multiple repositories to restrict the management servers that can control the agent.

This script sets a registry entry on the agent computer to explicitly allow a managed client to communicate with specified management servers from other management sites. The list of management servers with which the agent communicates is stored in the following registry key:

`\HKEY_LOCAL_MACHINE\SOFTWARE\NetIQ\4.0\NetIQMC\Security\AllowMS`

An asterisk (*) as a value for the `AllowMS` registry key authorizes all management servers to communicate with the agent. With this setting, "anonymous" management servers, servers with which the agent has not explicitly authorized communication, can communicate with the agent. This represents the lowest-security setting. It is the default if you do not choose to designate a primary management server during agent installation.

This script should not be used to enforce security or control communication between the management server and the managed client within a single site. Within a site, you should designate a primary and, if desired, a secondary management server for each agent. A separate registry key is involved in those designations; you can use the SetPrimaryMS Knowledge Script to identify the primary and secondary management server for each managed client within sites where more than one management server is installed.

You can specify the hostnames of allowed management servers for the *New hostname(s) for AllowMS* parameter. The computers you specify here will not become the agent's primary or secondary management server, but those computers can communicate with the agent and instruct it to run monitoring jobs.

7.27.1 Resource Objects

Windows 2000 Server or later

7.27.2 Default Schedule

The default interval for this script is **Run once**.

7.27.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
New hostname(s) for AllowMS	Specify a comma-separated list of computer hostnames to designate the management servers that are allowed to communicate with this agent. The `AllowMS` registry key will be set with this list as the value. **NOTE:** it is a good idea to use this script to allow management servers from other management sites to use this agent. For management server-to-agent communications within a single site, use the SetPrimaryMS Knowledge Script.
Raise event if attempt to set AllowMS succeeds?	Select **y** to raise an event if the job succeeds. The default is y.

Parameter	How to Set It
Event severity when attempt to set AllowMS succeeds	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25 (blue event indicator).

7.28 SetDataTimeStamp

Use this Knowledge Script to set the timestamp for data as it is referenced for reports. This setting affects all reports, but it does not affect areas other than reporting.

You can set one of three timestamps:

- **AppManager Repository** uses the local date/time of the AppManager repository computer.
- **Agent** uses the local date/time of the AppManager agent computer.
- **Custom** uses UTC (Coordinated Universal Time) plus or minus *N* hours.

By default, AppManager reports use the local time of the AppManager repository from which the reports are generated. Under circumstances where you want to have an AppManager repository-centric view of your data, you can leave these settings at their defaults.

Under circumstances where the accuracy of your reports depends on data being understood in the context of the local times during which it was collected, you would want to use the **Agent** timestamp. For example, if you are collecting data in four different time zones and want your report to include only data collected between 8 AM and 5 PM, you need that time frame to be relative to each time zone.

If you need to see all your data in the context of a specific time zone, you can use the **Custom** setting, and set the time zone by specifying the number of hours in positive or negative relation to UTC.

7.28.1 Resource Object

Report agent

7.28.2 Default Schedule

The default interval for this script is **Run once**.

7.28.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if timestamp successfully set?	Select **y** to raise an event if a timestamp is set successfully. The default is y.
Set timestamp to	Select a timestamp to use in reports: • **AppManager Repository** to set the timestamp to the local time of the AppManager repository. • **Agent** to set the timestamp to the local time of the AppManager agent that collected the data. • **Custom** to set the timestamp to a custom time (UTC plus or minus *N* hours). If you select this option, you must specify the number of hours in the following parameter.

Parameter	How to Set It
Custom time bias	Specify the number of hours by which UTC is modified. For example, if you enter 8, the time bias is Select UTC plus 8 hours. If you enter -8, the time bias is Select UTC minus 8 hours. Enter 0 to use UTC time.
Event severity when timestamp successfully set	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 35 (magenta level indicator).
Event severity when job fails	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 5 (red level indicator).

7.29 SetDeploymentWebService

Use this Knowledge Script to set or change the hostname of the Deployment Web Service with which the managed client should communicate to install the agents remotely.

NOTE: For details on installing the agents remotely, see the *User Guide for Control Center*.

The Deployment Web Service is normally set during agent installation. If for any reason you did not supply the hostname of the Deployment Web Service during agent installation, or if you need to change the Deployment Web Service that was set for an agent, use this script to set or change it.

The computer that hosts the Deployment Web Service must be accessible over the network via Port 80 to all managed clients.

This script sets the following registry key on the target computer:

`HKLM\SOFTWARE\NetIQ\AppManager\4.0\AgtShared\DeploymentEndpoint`

To disable communication with the Deployment Web Service, leave the *Name of Deployment Web Service* parameter blank.

NOTE: After you run this script, the AppManager agent may take up to six hours to report its software inventory to the deployment Web service. Restart the NetIQ AppManager Client Resource Monitor and NetIQ AppManager Client Communication Manager agent services to ensure that the agent reports its software inventory immediately.

7.29.1 Resource Objects

Windows 2000 Server or later

7.29.2 Default Schedule

The default interval for this script is **Run once**.

7.29.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if job succeeds?	Select **Yes** to raise an event if the job succeeds. This script always raises an event if the job fails.
Event severity when job succeeds	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25 (blue event indicator).
Event severity when job fails	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 10 (red event indicator).
Name of Deployment Web Service	Specify the hostname of the Deployment Web Service. To disable remote installation of agents, run the job with this parameter left blank.

7.30 SetKSStandby

Use this Knowledge Script to designate a selected managed client as a standby managed client for specified script categories and for the master managed client.

A *standby* managed client runs jobs only when the master managed client is down, or when jobs from the specified script category are blocked.

If a master managed client is currently configured, leave the *Hostname for master managed client* parameter blank to change it.

7.30.1 Resource Objects

Windows 2000 Server or later

7.30.2 Default Schedule

The default interval for this script is **Every hour**.

7.30.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Knowledge Script categories (comma-separated)	Specify the script categories for which the selected managed client will serve as a standby. Whenever a job from one of these categories cannot run because the agent that is supposed to run it cannot be reached, the job defaults to the standby. Separate the names of multiple script groups with commas and no spaces. The category name is shown on the script view tab for that category. For example, for Microsoft IIS, the category name is "IIS." The default is * (all script categories).
Hostname for master managed client	Designate the master managed client for the script category specified in the previous parameter by supplying its hostname.
Raise event if job succeeds?	Select **y** to raise an event if the job succeeds in designating a master managed client to serve as a standby for the specified script categories. The default is n.
Event severity when job succeeds	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25 (blue event indicator).

7.31 SetLocalRPSize

Use this Knowledge Script to modify the maximum number of events or data points that can be stored in the managed client's local repository. If the managed client is not able to communicate with the management server for any reason, the local repository for the managed client stores the most recent events and data points up to this limit until communication with the management server is restored.

If the number of events or data points exceeds the limit you have set (for example because of an extended network interruption), the oldest events or data records are lost as new events or data points are recorded.

Setting this registry key to 0 may affect the performance on the managed computer when a large number of records are inserted into the local repository (for example, because the management server is down, communication is disabled, or the managed computer is between scheduled uploads). If you are using ODBC, no changes are required.

7.31.1 Resource Objects

Windows 2000 Server or later

7.31.2 Default Schedule

The default interval for this script is **Run once**.

7.31.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Change maximum number of data points to store?	Select **y** to change the maximum number of data points that can be added to the local repository. The default is y.
Maximum number of data points to store	Specify the maximum number of data points that can be added to the local repository. Enter 0 if you do not want to set a limit on the maximum number of data points. The default is 10,000 data points.
Change maximum number of events to store?	Select **y** to change the maximum number of events that can be added to the local repository. The default is y.
Maximum number of events to store	Specify the maximum number of events that can be added to the local repository. Enter 0 if you do not want to set a limit on the number of events. The default is 10,000 events.
Raise event if repository configuration succeeds?	Select **y** to raise an event indicating the success or failure of the operation. The default is n.
Event severity when repository configuration...	Set the event severity level, from 1 to 40, to reflect the importance when the job: **... succeeds**. If you set this script to raise an event when the job succeeds, set the event severity level for a successful discovery. The default is 25 (blue event indicator). **... fails**. The default is 5 (red event indicator).

7.32 SetPrimaryMS

Use this Knowledge Script to designate the primary and secondary management server for an agent. If the primary management server fails, the secondary, or backup, management server takes over communication with the managed client until communication with the primary management server resumes.

Within an AppManager management site, the agent only accepts job requests and sends events to its designated management server. During installation, you can designate the agent's primary and optionally, a secondary management server. For performance reasons, you should always designate the primary and, if there is one, a secondary management server, within a management site.

After installation, use this script to add a secondary management server, or change the agent's designated primary management server. If you are managing a computer from more than one AppManager site, run this script from another site to designate the primary and secondary management server for that site.

If you are managing a client from more than one management site, run this script from each site to designate the primary and secondary management server for that site. To authorize an agent to communicate with an additional management server, use the AgentConfigMSRestrictions Knowledge Script.

The list of authorized management servers is updated to include the designated primary and secondary management servers. If the agent was configured to not allow anonymous management server communication, that communication restriction goes into effect after you designate the primary and secondary management server.

To improve repository performance, you should always designate a primary management server for each managed client computer in your site. If you cannot designate a primary management server during installation—for example, if the installation program cannot communicate with the management server—you must manually designate the primary management server using this script.

To configure a primary and backup management server for a managed Windows client, run this script and set the *Primary management server hostname* and *Backup management server hostname* parameters. After establishing a primary and backup management server for a managed client, you can also use this script to change the primary management server hostname, the backup management server hostname, or both using the *Select management server operation to perform* parameter:

Designation to Change	How to Change It
The managed client's **primary** management server	Enter a new hostname for the primary management server. Leave the *Backup management server hostname* parameter blank. Set the *Management server operation to perform* parameter to 1.
The managed client's **backup** management server	Enter the hostname of the existing primary management server. Enter a new hostname for the backup management server. Set the *Management server operation to perform* parameter to 2.
Both the **primary** and **backup** management servers	Enter a new hostname for the primary management server. Enter a new hostname for the backup management server. Set the *Management server operation to perform* parameter to 3.

Set the *Management server operation to perform* parameter properly to avoid unexpected behavior. For example, assume you want to establish the computer `BOSTON` as the primary management server, but do not want to make any change to the backup management server. If you run this script with the *Backup*

management server hostname blank but inadvertently set the *Management server operation to perform* parameter to 3, the empty *Backup management server hostname* parameter is not ignored. Because you have indicated you want to change both the primary and backup management servers, the blank entry for *Backup management server hostname* is interpreted as authorization for any available management server to act as a backup management server for the target managed client.

For more information about multiple management server configurations, see the *Administrator Guide for AppManager*.

7.32.1 Resource Objects

Windows 2000 Server or later

7.32.2 Default Schedule

The default interval for this script is **Run once**.

7.32.3 Setting Parameter Values

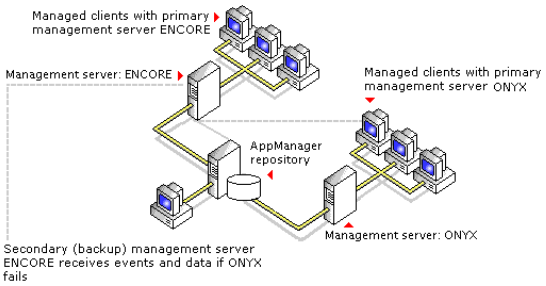
Set the following parameters as needed:

Parameter	How to Set It
Raise event if set operation succeeds or fails?	Select **y** to raise an informational event when the managed client is successfully updated with the new management server information or if the update fails. The default is n.
Event severity when set operation succeeds	Set the event severity level, from 1 to 40, to indicate the importance of a successful registration of the management server. The default severity level is 25.
Event severity when set operation fails	Set the event severity level, from 1 to 40, to indicate the importance of a event in which the registration of the management server fails. The default severity level is 10.
Primary management server hostname	Specify the name of the management server you want to use as the primary management server. **NOTE:** The value for this parameter cannot be blank, even if you are only setting the backup management server.
Backup management server hostname	Specify the name of the management server you want to use as the backup management server.
Management server operation to perform	Specify which management server configuration you want to update for the target managed client. Type: • **1** to change only the primary management server • **2** to change only the backup management server • **3** to change both the primary and backup management servers The default is to change the primary management server (1).

7.32.4 Example of How this Script Is Used

When you install the AppManager agent, you automatically designate a primary management server, and that management server becomes the only management server that the managed client communicates with for a single repository/management server configuration. A secondary or backup management server can also be defined at installation for each managed client in case the primary management server fails. The secondary management server only communicates with the managed client when the primary management server is unavailable. When communication with the primary management server resumes, the managed client resumes exclusive communication with the primary management server.

Because a multiple management server environment is chiefly intended for failover functionality (to provide an alternative management server if the primary management server fails), each managed client can have one primary management server and one backup management server for each repository.



In addition, identifying a specific management server for specific groups of managed clients gives you greater control over the distribution of communication load and network bandwidth usage.

7.33 SetReportPaths

Use this Knowledge Script to change the default output path used by the report agent.

You can also use this script to instruct the report agent to display the locations of reports as hyperlinks in events. By default, the absolute path to a report is displayed as text on the **Message** tab of the Event Properties dialog box. Use this script to display a hyperlink to the report in addition to the default text. Clicking the hyperlink opens an instance of Internet Explorer to display the contents of the report.

7.33.1 Resource Object

AM Repositories object under the Report agent

7.33.2 Default Schedule

The default interval for this script is **Run once**.

7.33.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event when change to report path succeeds?	Select **y** to raise an event when one or both of these paths are successfully changed. The default is y.

Base output path	Use this parameter to set a new base output path for the Report Agent.
	Type the path using the following format:
	`\\<server>\<share>\<path to folder>`
	where:
	`<server>` is the computer where you want to write reports.
	`<share>` is the share name of the drive where you want to write reports.
	`<path to folder>` is the absolute path to the folder where you want to write reports.
	For example, the base output path might be:
	`\\RptServer\C$\Program Files\NetIQ\ReportCenter\Web\Report`
	You can also use an absolute path for the value of this parameter. For example:
	`C:\Program Files\NetIQ\ReportCenter\Web\Report`
	NOTE: Leave this parameter blank if you are only using this script to set the *URL mapping* parameter.

Parameter	How to Set It
URL mapping	Use this parameter to set the URL mapping registry value. Type the URL to the AppManager Web Management Server using the following format: `<protocol name>://<web server name>` where: `<protocol>` is the Internet Protocol, either `HTTP` or `HTTPS`. `<web server name>` is the computer where you have installed the AppManager Web management server. **NOTE:** This parameter should be left blank if you are only using this script to set the *Base output path* parameter. This parameter must be set in order to successfully use Action_SMTPMailRpt.
Event severity when change to report path succeeds	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 35 (magenta level indicator).
Event severity when change to report path fails	Set the event severity level, from 1 to 40, to indicate the importance of the event when the job fails. The default is 5 (red level indicator).

7.34 SetResDependency

Use this Knowledge Script to define the resources required to run script jobs on a Windows computer. Resources can include physical file-system related resources such as logical disk drives or directories, or the availability of specific services. You can specify the dependency list by script category or define resources that apply to all script jobs.

The resources and services you specify must be active and available for jobs in the specified category to run. If any resource or service is not available, the jobs in the specified category are temporarily suspended until the specified resource or service becomes available.

Typically, this script is used to define shared cluster resources for physical cluster nodes. For information about running this script in active/passive and active/active cluster environments, see the chapter on cluster support in the *AppManager Administrator Guide*.

This script is used to ensure that jobs do not run when required resources are not available. For example, you may want to check that the MSSQLServer and SQLExecutive services are running before running SQL script jobs. To do this, set the *Knowledge Script category* parameter to `sql` and the *Required active services* parameter to `MSSQLServer,SQLExecutive`.

If you are monitoring a cluster environment, you use this script to identify the cluster resources for the active physical node. For example, assume you have an active/passive Exchange cluster with two physical nodes, `SHASTA` and `VENICE` and that this cluster uses the logical drive `M:` as its shared cluster resource. This shared cluster resource is only available to the active physical node. You use this script to ensure that the Exchange Knowledge Script jobs only run on the active node by setting the *Knowledge Script category* parameter to `exch` and the *Required available resources* parameter to specify the `M:` drive.

To remove dependencies, you must cold start the AppManager Client Resource Monitor and AppManager Client Communication Manager services using the `-o` start parameter.

7.34.1 Resource Objects

Windows 2000 Server or later

7.34.2 Default Schedule

The default interval for this script is **Run once**.

7.34.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Knowledge Script job categories	Indicate the script category for which you want to specify resource dependencies. To specify multiple categories, separate the names with commas and no spaces. The default is all (*) job categories.
Required available resources (	Specify the physical resources required for running jobs in the specified category. Physical resources are file-system based and can include logical disk drives, directories, or specific files. You can enter multiple resources, separated by commas with no spaces. For example: `J:,K:,K:\temp\test.log`

Parameter	How to Set It
Required active services	Specify the Windows services required for running jobs in the specified category. Active services are services that are running when checked. To specify multiple services, separate service names with commas and no spaces: `MSSQLServer,SQLExecutive`
Raise event when update to required resources succeeds?	Select **y** to raise an event indicating the success of the operation. The default is n.
Event severity when update to required resources succeeds	Set the event notification level to give you the desired visibility for a successful operation. By default, the severity level is 25 (blue event indicator).

7.35 SiteSchedUpload

Use this Knowledge Script to specify a schedule for uploading data and/or events from the managed client's local repository on Windows to the current management server. You can set up specific schedules for data, events, or both, as needed.

Depending on your selection, the Client Communication Manager agent service (`NetIQCCM`) stores the events or data points in the local repository until the scheduled upload time. At upload time, the `NetIQCCM` service reads the events and/or data points from the local repository and sends them to the management server. The upload time starts when the job is scheduled to start and ends when the job is scheduled to stop, as specified on the Schedule tab.

The size of message batches delivered in the upload is configured through the ConfigSiteNetFlowCtrl Knowledge Script. You can also configure the maximum number of data points or events to store in the local repository with the SetLocalRPSize Knowledge Script.

7.35.1 Resource Objects

Windows 2000 Server or later

7.35.2 Default Schedule

The default interval for this script is **Run once**. However, you should use the Schedule tab to set a schedule appropriate to your environment.

7.35.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Schedule upload time for data?	Select **y** to upload any data points stored on the managed computer to the central repository. The default is y.
Schedule upload time for events?	Select **y** to upload any events stored on the managed computer to the central repository. The default is n.
Raise event when attempt to set schedule succeeds?	Select **y** to raise an event indicating the success or failure of the operation. The default is n.
Event severity when attempt to set schedule...	Set the event severity level, from 1 to 40, to reflect the importance when the job: **... succeeds**. If you set this script to raise an event when the job succeeds, set the event severity level for a successful discovery. The default is 25 (blue event indicator). **... fails**. The default is 5 (red event indicator).

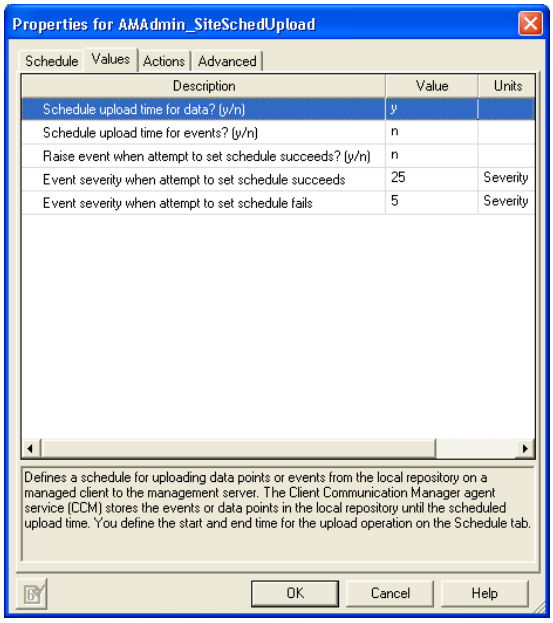
7.35.4 Example of How this Script Is Used

This script allows you to store performance and event data in the local repository until you are ready to upload it to the management server. By giving you the flexibility to transfer events and data during off-peak hours or when network traffic is light, the AppManager management server and repository can handle data from more servers and you can better manage network bandwidth.

For example, if you are collecting a significant amount of data on a few key managed clients, you may want to store the data locally on those managed clients while the network is busy, then transfer it to the management server at a time you know network traffic is light. In addition, you can schedule data from different managed clients to be uploaded at staggered times, further reducing the load on the management server and repository.

To use this script, set a schedule interval, start time, and end time on the **Schedule** properties tab. Click **Every** in the Frequency section to set an **End** time. The frequency interval (such as 5 Minutes) is ignored.

On the **Values** tab, you indicate whether this schedule applies to data, events, or both, and the event visibility. For example:



When you run this script on a target, the `NetIQccm` service immediately begins storing the specified information (in this case, data points) from all jobs running on the managed client in the managed client's local repository.

At the scheduled upload Start time (in this case, 1:00 a.m.), the information is transferred to the management server. If all the information in the local repository cannot be transferred to the management server, for example because the upload time is too short, any information not transferred remains in the local repository, up to the maximum number of events or data points that can be stored in the local repository. You can configure the maximum number of events or data points that can be stored in the local repository with SetLocalRPSize).

You can further control the flow of network traffic and the transfer of data from the managed client to the management server using the ConfigSiteNetFlowCtrl Knowledge Script.

7.36 UpgradeJobs

After you upgrade the AppManager agent, existing jobs on the managed client computer are not automatically upgraded to use the latest script functionality. Use this Knowledge Script to upgrade all child jobs for one or more parent jobs.

NOTE: The functionality provided in the latest version of the script may not be supported by older agents with older managed objects. For this reason, you should upgrade your managed clients to the latest version of the AppManager agent before you upgrade jobs running on those agents.

Upgrading jobs to use the latest script version allows the jobs to take advantage of the latest script logic while maintaining existing parameter values for the job, along with the associated graph data and event information. If the latest version of a script has been modified to have new parameters, for example, to create different events or datastreams, the default values in the latest script for the new parameters are used.

This script upgrades all child jobs for one or more parent jobs. You can select the parent jobs you want to upgrade based on the following:

- **Knowledge Script** — Select this option to upgrade all ad hoc jobs started by the specified script. This option upgrades ad hoc jobs started by a particular script and ad hoc jobs started by a Knowledge Script Group member. This option does not upgrade policy-based jobs.
- **Knowledge Script category** — Select this option to upgrade all ad hoc jobs started by the specified script category. This option does not upgrade policy-based jobs.
- **Parent job identifier** — Select this option to upgrade all ad hoc child jobs that belong to the specified Parent Job ID. This option does not upgrade policy-based jobs.
- **Monitoring policy** — All policy-based jobs started by the specified Knowledge Script Group are upgraded. If you are using a Knowledge Script Group in one or more monitoring policies, all affected monitoring policies are updated. This option does not upgrade ad hoc jobs started by a Knowledge Script Group.

NOTE: This script does not upgrade AppManager report Knowledge Script jobs, nor does it return a list of report Knowledge Scripts in an instant check query.

7.36.1 Version Compatibility

This script upgrades the following:

- AppManager jobs on a version 7.0 (or later) Windows agent
- Version 7.0 (or later) AppManager jobs on a version 8.0 (or later) UNIX agent

7.36.2 Performing an Instant Check Query before Running this Knowledge Script

Before you attempt to upgrade jobs using this script, you should identify jobs that have not yet been upgraded by performing an **instant check query**.

The instant check query provides a list of jobs to upgrade and jobs that have already been upgraded. You should use the instant check query to identify the jobs to upgrade and to develop a strategy for upgrading existing jobs.

The instant check query identifies jobs by AppManager version and displays both Windows and UNIX jobs. Use the name of the script category to identify Windows or UNIX jobs.

The query results for each job also include the version of the AppManager agent.

To perform an instant check query, use the **Instant Check Query** parameters on the Values tab. Use the *Select query* parameter to select the type of query you want. Then click **Browse** (**...**) in the *Display query* parameter to see the results of the selected query. To save the query results to a file, click **Finish**. You can run the following query types:

Query Type	Description
Out-of-date parent jobs	This query returns a list of parent IDs that you should upgrade. Note that some parent jobs may contain two different versions of a script. If that is the case, and either one of them is not the latest, the **KS Build ID** field reads "multiple build IDs."
Up-to-date parent jobs	This query returns a list of parent job IDs that are presently using the latest script in the repository and cannot be updated.
Old parent jobs with no upgrade	This query returns a list of jobs with an old script but for which there is no newer version in the repository. If this query returns any parent job IDs, it means the script has either been discontinued in later versions of AppManager, or it is a script you created or customized under a new name and for which you have yet to create a new version in the repository. When this query returns no values, then there are no parent jobs using out-of-date scripts. No further upgrading is required.
Child jobs on v6.x agents	This query returns a list of child jobs running on AppManager version 6.x agents.
Agent build IDs	This query returns a list of the agent build number on each computer. You can use this list to identify agents that you may want to upgrade.
Monitoring-policy jobs	This query returns a list of the jobs that are currently part of a monitoring policy. The jobs are listed according to the view or server group associated with the monitoring policy and then sorted by script group. Note that the Knowledge Script Group names (**KSGName** field) all have the prefix "KSG_." If you want to upgrade a Knowledge Script Group, add this prefix to the group name. You cannot upgrade any UNIX jobs that are policy-based. After you upgrade the backlevel UNIX agent to the latest version, remove the existing backlevel policy-based jobs and recreate them.

After you run an instant check query to identify the jobs you want to upgrade, you can generate a report that previews the jobs that would be upgraded. For more information, see "Viewing Job Upgrade Reports" on page 314.

7.36.3 Upgrading Jobs Created by a Custom Knowledge Script

If you have written a custom script, you do not need to upgrade existing jobs created by that script unless you have made changes to the script. In most cases, existing custom scripts can be run successfully on AppManager 7.0 (and later) agents.

7.36.4 Upgrading Jobs Created by a Copy of a Standard AppManager Knowledge Script

Before you can upgrade jobs created by a copy of a script, you must update the copy of the script in the AppManager repository:

To update a copy of a script:

1. On the repository computer, use Windows Explorer to open the `\netiq\appmanager\qdb\kp` folder and click the folder that contains the new version of the original script upon which the copy is based.
2. Copy the script and rename it to use the same name as the script copy.
3. Check the updated script copy into the repository. You are now ready to upgrade existing jobs.

7.36.5 Verifying Upgraded Jobs

To verify that a job has been upgraded, view the job properties.

To verify a job upgrade:

1. In the List pane in the Operator Console, double-click a child job on the Jobs tab.
2. In the Properties dialog box, click **View KS**.
3. In the Script for Job dialog box, verify the **AppManID** is **Select 7.0**.

7.36.6 Resetting Password Information for Upgraded Jobs

In some rare cases, running the AMAdmin_UpgradeJobs script replaces the existing password for your environment with the default password specified in the original script properties. After these jobs are upgraded, they no longer run because the password is incorrect. This problem occurs for the following scripts:

- NTADMIN_AddUser
- NTADMIN_ChangePassword
- SQL_Bcp

If you upgrade any of these script jobs, update the job properties to restore the correct password information.

7.36.7 Resource Objects

Run this script on a managed Windows computer with the AppManager 7.0 (or later) agent where the "Log On As" account for the AppManager agent Client Resource Monitor (`NetIQmc`) service is a valid domain user account that belongs to the AppManager **Administrator** role.

To verify that the Windows user account that the AppManager agent uses belongs to the AppManager **Administrator** role, in AppManager Security Manager expand **AppManager Roles** in the Navigation pane or the TreeView and click **Administrator** to see a list of valid AppManager administrators.

7.36.8 Default Schedule

The default interval for this script is **Run once**.

7.36.9 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Instant Check Query	
Select query	The instant-check query provides a list of jobs to upgrade and jobs that have already been upgraded. You should use the instant check query to identify the jobs to upgrade and to develop a strategy for upgrading existing jobs. For more information, see "Performing an Instant Check Query before Running this Knowledge Script" on page 310.
Display query	Click **Browse [...]** to see a list of Knowledge Script jobs found by the instant check query.
Job Options	After you use *Instant check query* to identify the jobs you want to upgrade, use these parameters to generate a preview of the changes to the script that will be applied to existing jobs and to actually apply those changes and upgrade the jobs.
Upgrade jobs, or generate report?	Select one of the following options: • **Generate report** To preview detailed information about which jobs would be upgraded based on your selection criteria, select this option. If you select this option, no jobs are upgraded. This option provides detailed information about the changes to the actual script, including a list of new or changed parameters. If the latest script has new or changed parameters, you can preview the default values for these parameters before they are applied when you upgrade. • **Upgrade jobs** This option upgrades jobs based on your selection criteria. The default is Generate report. For more information, see "Viewing Job Upgrade Reports" on page 314.
Force, or restricted upgrade?	Select an option for upgrading parent jobs: • **Restricted** This option only upgrades a parent job if all of its child jobs are running on AppManager agents that have been upgraded to the latest version. If one of the child jobs for the specified parent job is running on an older agent, none of the child jobs are upgraded. • **Warning** When using the **Restricted** option, this script does **not** raise an event after unsuccessfully attempting to upgrade jobs on an older agent. Before you select this option, be sure to use the Instant Check Query to verify that there are no jobs running on older agents. • **Force** This option upgrades all of the child jobs for a parent, including child jobs that are running on an agent that has not been upgraded to the latest version. • **Warning** When using the **Force** option, this script does **not** raise an event after unsuccessfully attempting to upgrade jobs on a version 4.3 or 5.0 UNIX agent. If you are upgrading UNIX jobs, be sure to use the Instant Check Query to verify that there are no jobs on version 4.3 and 5.0 UNIX agents. Note that in some cases, the functionality provided in the latest version of the script logic may not be supported by older agents with older managed objects. The default is Restricted.

Parameter	How to Set It
Override job build version?	Set to **y** to upgrade jobs regardless of the job build version (force job upgrade). This option is required to upgrade jobs that have a build version that is the same or earlier than the script build version. The job upgrade process uses **all numbers** of the build version to compare versions. For example, if the build version for an AppManager job is **7.0.2** and the build version of the newer script is **7.0.112**, the job upgrade mechanism would **not** upgrade the job unless you enabled this option. The default is y. **Tip** To view the build version: • For a job, click the **View KS Script** button on the **Values** tab of the Job Properties dialog box. In the Script dialog box, the **AppManID** value specifies the build version. • For a script, in the Operator Console, right-click the script and click **Version History**. In the **Version** dialog box, the build version appears in the **Build ID** column.
Job selection criterion	Specify how to select the jobs you want to upgrade. You can select jobs by: • **Knowledge Script** Select this option to upgrade all ad hoc jobs started by the specified script. This option upgrades ad hoc jobs started by a particular script and ad hoc jobs started by a Knowledge Script Group member. This option does not upgrade policy-based jobs. • **Knowledge Script Category** Select this option to upgrade all ad hoc jobs started by the specified script category. This option does not upgrade policy-based jobs. • **Parent Job Identifier** Select this option to upgrade all ad hoc child jobs that belong to the specified parent job. This option does not upgrade policy-based jobs. • **Monitoring policy** All policy-based jobs started by the specified Knowledge Script Group are upgraded. This option does not upgrade ad hoc jobs started by a Knowledge Script Group. **Warning** If you are using a Knowledge Script Group in more than one monitoring policy, all affected monitoring policies are updated.
Job selection specification	Select the jobs you want to upgrade from a list, based on a job selection criterion. Click **Browse** (**...**) to see the list. If your job selection criterion is: • **Knowledge Script**, this list allows you to select the scripts you want to upgrade. This list only displays scripts that have a corresponding ad hoc job. • **Knowledge Script Category**, this list allows you to select the script categories you want to upgrade. This list only displays script categories that have a corresponding ad hoc job. • **Parent Job Identifier**, this list allows you to select one or more parent jobs. This list only displays parent job identifiers for ad hoc parent jobs. • **Monitoring policy**, this list allows you to select all policy-based jobs that belong to the specified Knowledge Script Group. This list only displays Knowledge Script Groups that belong to a monitoring policy. **Warning** If you are using a Knowledge Script Group in one or more monitoring policies, all monitoring policies are updated.

7.36.10 Viewing Job Upgrade Reports

Each time you run this script, job upgrade reports are created under:

`\netiq\temp\netiq_debug\{ computer}\jobupgrade`

where *computer* is the name of the computer where you ran the report. The following reports are always generated regardless of whether you configure this job to generate a report or upgrade jobs:

- `Upgradejob_id.txt, where id` is the UpgradeJobs ID, provides information about which jobs are upgraded.
- `Upgradejob_id.rpt`, where *id* is the UpgradeJobs job ID, provides detailed information about each job.

TIP: `Upgradejob_id.log`, `where id` is the UpgradeJobs ID, lists the Job IDs that are upgraded and references the corresponding `.rpt` file and `.log` files for more information.

If the child of a specified parent job is running on an agent that has not been upgraded to the latest version, and you specified the **Restricted** upgrade option, the `UpgradeJob_<id>.txt` file displays information similar to the following:

```
Connected to SQL Server : RACKR14 repository QDB.
Time stamp: 03/03/07 14:20:47
  [Child Job] [Parent Job] [Build ID]  [Computer\KS]
2 4.3 agent(s) found.
2 5.0 agent(s) found.
1 5.0.1 agent(s) found.
Parent job 436 is skipped because under restricted mode, there cannot be any
non-7.0 agents.
Upgrade is finished.
Please check upgradejob_1343.rpt and upgradejob_1343.log located in
D:\NetIQ\Temp\NetIQ_Debug\RACKR14\jobupgrade.
Time stamp: 03/03/07 14:20:47
```

If the child of a specified parent job can be upgraded with parameter changes, the `UpgradeJob_<id>.rpt` file displays information similar to the following:

```
Connected to SQL Server : RACKR14 repository QDB.
Time stamp: 03/03/07 15:14:30
************************************************************
Parent job 54 can be upgraded under force mode.
2 4.3 agent(s) found.
2 5.0 agent(s) found.
2 5.0.1 agent(s) found.
1)
Child job ID = 55
Parent job ID = 54
KS name = NT_CpuLoaded
Machine name = RACKN08
Version = 4.6
Job 55 can be upgraded.
The following parameters in the existing job are not found in the new version
of the KS:
1) Event? (y/n)
Existing value is y.
2) Collect Data? (y/n)
Existing value is y.
3) Overall Load? (y/n)
Existing value is y.
```

```
4) Cpu Threshold >
Existing value is 0
5) Cpu Queue Length >
Existing value is 0
6) Event Severity
Existing value is 5
7) Severity for an unexpected KS error
Existing value is 35
The following parameters in the new version of the KS are not found in the
existing job:
1) Event Notification
Default value is NULL.
2) Create event if total system CPU is high?
Default value is y.
3) Severity - Total system CPU
Default value is 5
4) Create event if any individual CPU is high?
Default value is n.
5) Severity - Individual CPU
Default value is 15
6) Severity - Job failure
Default value is 35
7) Data Collection
Default value is NULL.
8) Collect total system utilization data?
Default value is y.
9) Collect individual processor utilization data?
Default value is n.
10) Collect processor queue data?
Default value is y.
11) Monitoring
Default value is NULL.
12) Threshold - Total system CPU
Default value is 0
13) Threshold - Individual CPU
Default value is 98
14) Threshold - Processor queue length
Default value is 0
Check for OldParameter tag
1) Create event if total system CPU is high?
Default value is y
OldParameter tag value = ?DO_EVENT="y" ((AND)) DO_OVERALL="y":"y":"n".
New StringValue = "y"
2) Severity - Total system CPU
Default value is 5
OldParameter tag value = ?DO_EVENT="y" ((AND))
DO_OVERALL="y":Severity:$default$.
New IntValue = "5"
3) Create event if any individual CPU is high?
Default value is n
OldParameter tag value = ?DO_EVENT="y" ((AND)) DO_OVERALL="n":"y":"n".
New StringValue = "n"
4) Severity - Individual CPU
Default value is 15
```

```
OldParameter tag value = ?DO_EVENT="y" ((AND))
DO_OVERALL="n":Severity:$default$.
No matching value, will keep original.
5) Severity - Job failure
Default value is 35
OldParameter tag value = PRM_KSERR.
New IntValue = "35"
6) Collect total system utilization data?
Default value is y
OldParameter tag value = ?DO_DATA="y" ((AND)) DO_OVERALL="y":"y":"n".
New StringValue = "y"
7) Collect individual processor utilization data?
Default value is n
OldParameter tag value = ?DO_DATA="y" ((AND)) DO_OVERALL="n":"y":"n".
New StringValue = "n"
8) Collect processor queue data?
Default value is y
OldParameter tag value = DO_DATA.
New StringValue = "y"
9) Threshold - Total system CPU
Default value is 0
OldParameter tag value = ?DO_OVERALL="y":TH_UTIL:$default$.
New IntValue = "0"
10) Threshold - Individual CPU
Default value is 98
OldParameter tag value = ?DO_OVERALL="n":TH_UTIL:$default$.
No matching value, will keep original.
11) Threshold - Processor queue length
Default value is 0
OldParameter tag value = TH_QLEN.
New IntValue = "0"
```

If the child of a specified parent job cannot be upgraded because the UNIX agent on which it is running is version 6.5, the entry looks like this:

```
Parent job 1536 cannot be upgraded under restricted mode.
29 6.5 agents are found.
Please upgrade these agents and restart the upgrade process.
```

In this case, upgrade the agent or use the *Force upgrade* parameter to upgrade the jobs on the older agent.

8 AMAdminUNIX Knowledge Scripts

AppManager for UNIX provides the following Knowledge Scripts to perform administrative tasks for UNIX agents and your AppManager system. In addition to the AMAdminUNIX Knowledge Scripts, the AppManager for Self Monitoring Knowledge Scripts provides information about the health of your AppManager components.

From the Knowledge Script view of the Control Center Console, you can access more information about any NetIQ-supported Knowledge Script by selecting it and pressing **F1**. Or in the Operator Console, click any Knowledge Script in the Knowledge Script pane and press **F1**.

Knowledge Script	What It Does
AgentHealthProxy	Checks the availability of a remote managed UNIX computer and monitors the health of the remote UNIX agent. This Knowledge Script uses a proxy UNIX agent to monitor remote UNIX agents.
AgentInstallProxy	Installs the 7.0.1 AppManager UNIX agent on remote UNIX and Linux computers in your network. This Knowledge Script uses a proxy AppManager UNIX agent to install on remote computers. To remotely install NetIQ UNIX Agent 7.1 or later, use NetIQ UNIX Agent Manager.
AgentUpdate	Updates the 6.x AppManager UNIX agents remotely on computers in your network. To update NetIQ UNIX Agent 7.1, use NetIQ UNIX Agent Manager.
AgentUpdateSecurityLevel	Updates the security level for the UNIX agent remotely on UNIX client computers in your network.
SchedMaint	Sets a server maintenance period for a managed computer. During the maintenance period, regularly scheduled jobs are prevented from running.
SetPrimaryMS	Sets the primary and secondary management server for UNIX agents in multiple management server configurations.

8.1 AgentHealthProxy

Run this Knowledge Script on an AppManager 7.0 or later UNIX agent to monitor the health of one more remote AppManager 7.0 or later UNIX agents.

When you drag this Knowledge Script to a computer in the TreeView, the Knowledge Script runs on that machine and tries to communicate with each of the remote computers in the machine list. This Knowledge Script:

- Checks the availability of a managed UNIX computer by first sending an ICMP Echo request to the managed UNIX computer. If the remote computer does not respond, this Knowledge Script sends an ICMP Echo request to the managed UNIX computer's default router and an event is raised.
- Monitors the health of the UNIX agent by checking a timestamp value created by the UNIX agent. Normally, the UNIX agent creates a timestamp value every 90 seconds. If the age of the timestamp value exceeds the threshold, an event is raised and the UNIX agent is restarted.
- This Knowledge Script enables self-monitoring of the UNIX agent health by raising appropriate events. You can use these events to correct unhealthy agents by restarting etc. This feature also enables you to restart unhealthy agents automatically without any manual intervention.

Use this Knowledge Script to remotely validate the health of the UNIX agent on a scheduled basis or for diagnostic purposes (for example, if there are gaps in data collection). This Knowledge Script is useful because it can detect a problem with a remote agent and reliably notify the AppManager administrator.

The proxy UNIX agent that runs the Knowledge Script must be configured to run as the **root** user account.

The remote UNIX agents you want to monitor, and the proxy UNIX agent that runs the Knowledge Script, must be Version 7.0 or later. The remote UNIX agents must be accessible through the network from the computer where the proxy UNIX agent is installed. If you attempt to use this Knowledge Script to monitor a UNIX agent that is earlier than version 7.0, an event is raised that indicates "the timestamp is not found."

Do not use this Knowledge Script to monitor the health of the UNIX agent that runs the Knowledge Script. To successfully monitor the health of the proxy UNIX agent, run this Knowledge Script on another proxy UNIX agent.

To use this Knowledge Script to monitor more than one remote managed UNIX computer, all of the computers you want must be accessible using the same **root** user account information.

NOTE: Ensure that the nqmdaemon config file in the remote managed UNIX computers are not renamed to effectively monitor them.

This Knowledge Script can use either the Secure Shell (SSH) program with root password authentication or Telnet to make a secure connection to the remote UNIX or Linux computer. By default, SSH is used, but you can select **Telnet/FTP** from the **Connection Transport** list to use Telnet instead. If you choose to use Telnet, you must supply a non-root user account name and password.

NOTE: Telnet and FTP send your username, password, and other information across the network in cleartext, making it easy for others to see this data.

If you are using Telnet to monitor the remote managed UNIX computer, ensure that su permission are given in the remote managed UNIX computer for that username.

8.1.1 Resource Objects

A managed UNIX computer where the NetIQ UNIX Agent 7.1 is installed. The UNIX agent must be configured to run as the **root** user account.

8.1.2 Default Schedule

The default interval for this script is **Every 10 minutes**.

To avoid raising false events, do not configure this Knowledge Script to run more frequently than the interval that the UNIX agent updates its timestamp. Ideally, the default interval should be more than 4 minutes.

8.1.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event Notification	
Use the following parameters to raise events and set the severity level.	
Raise event if age of timestamp exceeds threshold?	Select Yes to raise an event when the age of the timestamp exceeds the maximum threshold you set. The default is Yes.
Threshold – Maximum age of timestamp	Enter the maximum age of timestamp before an event is raised. The minimum threshold is 3 minutes and the maximum threshold is 99999 minutes. The default is 9 minutes.
Event severity when age of timestamp exceeds threshold	If the age of the UNIX agent's timestamp value exceeds the specified threshold, set the event severity level, from 1 through 40, to indicate the importance of this event condition. The default severity is 8.
Remote Host Connection	
UNIX computers to monitor (comma-separated)	Enter the IP addresses of the remote UNIX computers you want to monitor, separated by commas and no spaces.
Password for root user account	Enter the root user account password that the proxy agent must use to connect to the remote UNIX computer. This is a mandatory field.
Connection Transport	Specify the connection mode between the proxy agent and the monitored UNIX computer: • **Telnet/FTP** to connect using Telnet. • **SSH/FTP** to connect using SSH.
Telnet non-root user account	Enter the Telnet non-root user account if you are using Telnet to connect to the monitored computer.
Telnet non-root user password	Enter the Telnet non-root user password if you are using Telnet to connect to the monitored computer. Leave this parameter value blank if you are using SSH to connect to the monitored computer.
Restart UNIX agent if age of timestamp exceeds threshold?	Select Yes to restart the UNIX agent if the age of the timestamp exceeds the maximum age you set. The default is Yes.

NOTE: When running the AMADMINUNIX_AgentHealthProxy Knowledge Script with Secure Shell (SSH) as the connection method to the remote UNIX or Linux computer, if you specify an incorrect password for the root account, the Knowledge Script raises an event that incorrectly states that the login attempt was successful. If you see an event message similar to the event message below, you must update the job properties to specify the correct root password and start the job:

```
Output: Permission denied at /usr/netiq/AM/bin/UnixAgentHealthProxy.pl
More Info:
"SSH login OK to <machine> with root Using SSH/SFTP combination."
```

8.2 AgentInstallProxy

Use this Knowledge Script on a version 7.0.1 proxy AppManager UNIX agent to install a version 7.0.1 or earlier AppManager UNIX agent on remote UNIX and Linux computers in your AppManager site.

You cannot use this Knowledge Script to install a version 7.1 or higher NetIQ UNIX agent.

To install the AppManager UNIX agent on a remote UNIX or Linux computer, the remote computer must be accessible through the network from the computer where the proxy AppManager UNIX agent is installed. This Knowledge Script can use either the Secure Shell (SSH) program with root password authentication or Telnet to make a secure connection to the remote UNIX or Linux computer. By default, Telnet is used, but you can select SSH/SFTP from the **Connection Transport** list to use Secure Shell instead. If you choose to use Telnet, you must supply a non-root user account name and password.

This Knowledge Script uses a version 7.0.1 AppManager UNIX agent as the proxy to install the version 7.0.1 AppManager UNIX agent on remote UNIX and Linux computers.

8.2.1 Running this Knowledge Script

The proxy AppManager UNIX agent where you run this Knowledge Script must be configured to run as the `root` user account.

All of the computers where you want to install the AppManager UNIX agent using this Knowledge Script must be accessible using the same root user account information.

The failure messages associated with a scenario where you inadvertently tried to run with an invalid root user account password might not clearly state this fact. If you see a failure that states, for example, "`Cannot switch to root user on [X computer],`" "`Permission denied at UnixAgentInstallProxy.pl line X,`" "`unable to get a session to start the Installation,`" or "`Unable to get a session to start the Installation for [X computer],`" first check to make sure you are using a valid root password.

If the `.tar` file or `.ini` file that you have specified for the "**Installation Source Configuration**" parameter (that is, the file that you intend to use for the installation on a remote computer) already exists in the directory you listed for the **Temporary directory on the remote computer** parameter, you see a failure. The event states, "`Can't FTP File <File Name>: permission denied.`" If this occurs, run the job again. After the initial failure, the `.tar` or `.ini` files are removed from the directory.

When you run this Knowledge Script using a hosts file, the hosts file should list any file locations of `.ini` files before it lists locations of `.tar` files. The job fails and the Knowledge Script transfers the `.tar` file and never transfer the `.ini` file unless you make sure to list the `.ini` files first.

8.2.2 Platform Support

This Knowledge Script supports all platforms supported by the AppManager UNIX agent 7.0.1, with the following exceptions:

- HP-UX in 32-bit and 64-bit mode is supported. Most AMAdminUNIX and UNIX Knowledge Scripts can run on HP-UX in 64-bit mode (because you can install and run the AppManager UNIX agent there). However, a computer running HP-UX in 64-bit mode cannot serve as a proxy.
- Red Hat Advanced Server (AS) 3.0 on Opteron with 64-bit operating system is supported with the AppManager UNIX agent running in 32-bit mode.
- Red Hat AS 3.0 on Itanium in 64-bit mode is supported.

8.2.3 Resource Objects

A managed UNIX computer where the AppManager UNIX Agent 7.0.1 is installed. The AppManager UNIX agent must be configured to run as the root user account.

8.2.4 Default Schedule

By default, this Knowledge Script is **only run once on each proxy UNIX computer**.

8.2.5 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event Notification	
Set parameters for event notification.	
Raise event if installation fails?	Set to y to raise an event indicating that the installation has failed. By default, events are enabled.
Event severity when installation fails	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 10.
Raise event if installation succeeds?	Set to y to raise an event indicating that the installation is complete and has succeeded.The default is y.
Event severity when installation succeeds	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Remote Host Connection	
Configure access to the remote managed computers by specifying their root password. All of the remote computers must use the same root password. This Knowledge Script can use SSH with root password authentication or Telnet to communicate with the remote managed computer.	
Password for root user account	If you want to use Secure Shell (SSH) for the connection to the remote computers, make sure SSH with root authentication is enabled on the remote UNIX computers where you want to install the AppManager UNIX agent. For this parameter, you must specify the password for the root user to securely access the remote UNIX computers. This Knowledge Script does not support SSH root authentication with an RSA key.

Description	How to Set It

Connection Transport	This Knowledge Script can use SSH with root password authentication or Telnet to communicate with the remote managed computer.
	
	If you select the Telnet/FTP option (the default), the Telnet prompt on the remote computer must end with a space or one of the following characters:
	
	`%`
	`>`
	`#`
	`$`
	
	Here is an example of a supported Telnet prompt:
	
	`user@hostname>`
	
	Here is an example of an unsupported Telnet prompt:
	
	`<user@hostname:/tmp - 2005-Mar-09>`
	`->`
	
	In the example above, the last character in the first line of the 2-line prompt is a line feed character, which is not supported.

Telnet non-root user account	If you selected Telnet to connect to the remote UNIX computers, specify a non-root user account to use for the connection. When connecting to a remote UNIX computer using Telnet and FTP, this Knowledge Script switches from the non-root user to the root user.
Telnet non-root user password	If you selected Telnet as the connection transport medium, specify the password for the non-root user account to connect to the remote UNIX computers.

Installation Source Configuration

Set parameters to specify the remote computers where you want to install the AppManager UNIX agent, and the location of installation tar package and the silent installation file.

The simplest way to configure and run this Knowledge Script is to store the installation `.tar` packages and the silent installation files in the same directory, using the standard naming convention. If these files are in the same directory and use the standard naming convention, you simply specify the remote UNIX computers where you want to install the AppManager UNIX agent and the directory where the installation files are located.

For installation `.tar` packages, the following naming convention applies:

- `UnixClient-aix.tar` for IBM AIX computers
- `UnixClient-hpux.tar` for HP-UX computers
- `UnixClient-linux.tar` for Red Hat and SuSe Linux computers
- `UnixClient-solaris.tar` for Sun Solaris computers

For silent installation files, the following naming convention applies:

- `UnixClient-aix.ini` for IBM AIX computers
- `UnixClient-hpux.ini` for HP-UX computers
- `UnixClient-linux.ini` for Red Hat and SuSe Linux computers
- `UnixClient-solaris.ini` for Sun Solaris computers
- `UnixClient-linux64` for Red Hat Linux on Itanium processors

If you do not use these standard names, you must specify the directory path and filename.

Description	How to Set It
Full path to hosts file or comma-separated list of computers where agent should be installed	Specify the computers you want by either: • Entering the full directory path and filename for the hosts file that contains a list of the remote managed UNIX computers where you want to install AppManager UNIX agents. For example, `/home/appmgr/agtinstalltarget`. This option enables you to configure different installation `.tar` packages and silent installation files for each computer. In the hosts file, list each hostname on a new line, for example: `labuws202::/agt/ua-usr.ini::/agt/UnixClient-linux.tar` where: – `labuws202` is the name of the computer where you want to install the AppManager UNIX agent – `/agt/ua-usr.ini` is the file path to the silent installation file – `/agt/UnixClient-linux.tar` is the directory path to the agent installation package. The naming convention for the `.tar` files is explained in the help for the previous parameter. **TIP:** To comment out a line in the hosts file, use a # character. The hosts file should list any file locations of `.tar` files before it lists locations of `.ini` files. See "Running this Knowledge Script " on page 323, above, for more information. • Specifying a comma-separated list of UNIX computers. If you use a list of computers instead of using a hosts file, you must also configure this Knowledge Script to specify the name and location of the silent installation file and the installation tar package. All the computers in the list must be installed using the same installation .tar package and silent installation file. This Knowledge Script attempts to install the AppManager UNIX agent on the first computer in the list. If an error occurs, or when the installation completes, the Knowledge Script attempts to install the AppManager UNIX agent on the next computer in the list. **Tip** To use this Knowledge Script to install the AppManager UNIX agent on multiple remote UNIX or Linux computers, all of the target computers must be using the same root password.
Installation without Hosts File	If you do not configure this Knowledge Script to use a hosts file, you must specify where the AppManager UNIX agent installation tar package and the silent installation file are located.
Directory path to agent installation .tar package(s)	If you have configured this Knowledge Script to use a hosts file, you do not need to configure this parameter. Enter the full path from the remote UNIX or Linux computer to the directory where the installation `.tar` package is located. For example: `/usr/local/agt` You do not need to specify the name of the installation tar package if the name of the installation tar package follows the naming convention. If the name of the file does not follow the naming convention, you must specify the path and filename.

Description	How to Set It
Name of silent installation file	If you have configured this Knowledge Script to use a hosts file, you do not need to configure this parameter. You do not need to configure this parameter if the name of the silent installation file follows the naming convention **and** the silent installation file is located in the same directory as the AppManager UNIX agent installation .tar package. If the name of the silent installation file does not follow the convention (but it is in the same directory as the installation package), enter the name of the silent installation file. If the silent installation file is not in the same directory as the installation `.tar` package, enter the directory path and name of the silent installation file. For example: `/usr/local/agt/UnixClient-Linux.ini`.
Installation Destination Specify a temporary directory on the remote computer to store a copy of installation files. Note that if AppManager UNIX agent communication is authenticated and encrypted (security level 2), this Knowledge Script does not copy the security key with the installation files. Make sure that the remote UNIX computer can access the key file according to the location specified in the silent installation file.	
Temporary directory on the remote computer	Specify the name of a temporary directory on the remote computer where you want to install the AppManager UNIX agent. This Knowledge Script copies the installation `tar` package and related files, such as the hosts file and the silent installation file to the temporary directory. Note that some operating systems have small `/tmp` directories, which can prevent this Knowledge Script from successfully copying the installation files and untarring the installation `.tar` package. For this reason, you can specify a directory other than `/tmp`. If the `.tar` file already exists in this directory, you see a failure the first time you run this Knowledge Script. See “Running this Knowledge Script ” on page 323, above, for more information.
Installation command to run on the remote computer	Type the full command to use to install the AppManager UNIX agent on the target computer. The default is `UnixClient/netiq_agent_install`.

8.3 AgentUpdate

Use this Knowledge Script to remotely update a 6.0.2 or 6.5 AppManager UNIX agent to version 7.0.1, and to update a module on the 7.0.1 agent computer. To use this Knowledge Script, the AppManager UNIX agent you want to update must run as **root**.

To update a version 7.0.1 AppManager UNIX agent to version 7.1, and to update modules on a version 7.1 NetIQ UNIX agent, use NetIQ UNIX Agent Manager. For more information, see the UNIX Agent Manager online Help.

This Knowledge Script updates the AppManager UNIX agent and any modules on the computer separately. For example, if you have a managed client with the 6.5 version of the AppManager UNIX agent and AppManager for Apache management files, run this Knowledge Scirpt to update the AppManager UNIX agent to version 7.0.1. After you update the agent, configure this Knowledge Script to update the AppManager for Apache module on that computer.

To update the AppManager UNIX agent and preserve the agent's existing configuration, you must set the `INHERITCFG` flag in the silent installation file to `y`. For more information, see AgentUpdate.

This Knowledge Script does **not** change the user account under which the AppManager UNIX agent runs. To change the AppManager UNIX agent's account, you must manually run the installation script on the managed client computer.

This Knowledge Script is configured by default to raise an event when:

- The agent update completes successfully. In this case, the following event message is displayed: "`Agent successfully upgraded to version` *build_number*."
- The update is in progress but was not completed within the expected 4-minute time period. In this case, the following event message is displayed: "`Agent upgrade started. Run this job again to check the status of the upgrade and clean up temporary files`." To verify that the update completed successfully, re-run this Knowledge Script on the managed UNIX client computer.

8.3.1 User Account Requirements for this Script

To run this Knowledge Script, the AppManager UNIX agent you want to upgrade must run as **root**. If the AppManager UNIX agent runs as a non-root user, you must run the interactive installation script on the local computer to upgrade the AppManager UNIX agent.

8.3.2 Resource Objects

A 6.0.2 or 6.5 AppManager UNIX agent or a module on a 7.0.1 (or earlier) AppManager UNIX agent.

8.3.3 Default Schedule

By default, this script is only run once for each computer.

8.3.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Raise event if the update succeeds? (y/n)	Set to **y** to raise an event indicating the upgrade was successful. If the upgrade fails for any reason, an event is generated regardless of how you set this parameter. The default is `y`.
Type of installation package (d for directory, t for tar file)	Type **d** if the installation files are uncompressed and located in a distribution directory. For example, type `d` if the installation files are located on a mounted CD drive or have been copied to a specific directory. Type `t` if the installation files are packaged in a tar file. The default is `d`. • If set to "`d`" for directory, the path you specify for the following parameter needs to point to the fully qualified path of the expanded tarball. • If set to "`t`" for tarball packaging, the path you specify for the following parameter needs to point to the fully qualified file name of the tarball, for example, `/home/appmanager/upgradefiles/UnixClient-aix.tar` for an AIX upgrade, where "`aix`" is the operating system on the target computer. **NOTE:** Using the `tar` file requires additional scratch space in the temporary directory you specify on the target computer.
Full path to directory with UNIX agent .tar files	Enter the full path to the AppManager UNIX agent installation `.tar` file or the extracted contents of the `.tar` file. Typically the installation package is located on an accessible distribution computer. If you are working with the extracted contents of more than one `.tar` file, to avoid overwriting installation files you should extract each `.tar` file into its own shared directory. If the type of installation package is: • a `.tar` file, specify the full path to the `.tar` file. • extracted contents of the `.tar` file, specify the directory where the `netiq_agent_install` script is located.
Temporary working directory on the target computer	Specify a directory on the target computer to use as a temporary work space for upgrading the AppManager UNIX agent. Because the upgrade process creates a backup of your previous installation and verifies the success of the upgrade before removing any temporary files, the file system must have at least 200 MB of disk space available. The default is `/tmp`.
Full path to silent configuration file	Enter the full directory path to the silent installation file you'd like to use for the update. The default is `/tmp/silent.ini`.
Event severity when job aborts	Set the event severity level, from 1 to 40, to indicate the importance of the event when the job failed to update the agent. The default is 10.
Event severity when update fails	Set the event severity level, from 1 to 40, to indicate the importance of an event when the agent was not successfully updated. The default is 10.
Event severity when update succeeds	Set the event severity level, from 1 to 40, to indicate the importance of the event when the agent has been successfully updated. The default is 20.

8.4 AgentUpdateSecurityLevel

Use this Knowledge Script to remotely update the agent security level on the managed UNIX computers in your site. When configuring the security level for the agent, keep in mind that all managed UNIX clients in an AppManager site must be configured to use the same security level.

Use this Knowledge Script to change the security level on the managed UNIX clients in your AppManager site either before or after you change the security level on the repository database. The new security level takes effect on the managed UNIX client as soon as the Knowledge Script completes.

Keep in mind that managed UNIX clients cannot communicate with the management server until the security level on the managed UNIX client and the repository database are the same. After you restart the management server to use the latest security settings in the repository, managed UNIX clients with the corresponding security level can resume communication with the management server, and the Operator Console displays a success event message for this Knowledge Script job.

For more information about implementing AppManager secure communication, see the *Administrator Guide*.

The following security levels are available:

- **0 - Cleartext – no security** indicates that all communication between the agent and the management server is in cleartext and is not encrypted.
- **1 - Encryption – medium security** indicates that all communication between the agent and the management server is encrypted but the agent does not authenticate the identity of the management server.
- **2 - Encryption and authentication – highest security** indicates that the agent attempts to authenticate the identity of the management server before sending and receiving encrypted communication. This option is only applicable if you installed the agent with **Encryption and Authentication**.

Tip If you configured the agent at installation to use **Cleartext** or **Encryption** and you want to change the security level to **Encryption and authentication**, you must reinstall the agent or manually change the agent's configuration file.

8.4.1 Resource Objects

UNIX Server computers with the agent.

8.4.2 Default Schedule

By default, this Knowledge Script is only run once for each computer.

8.4.3 Setting Parameter Values

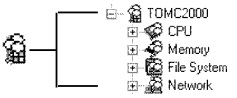
Set the following parameters as needed.

Description	How to Set It
Raise event when update succeeds or fails? (y/n)	Set to y if you want AppManager to raise an event when the security level is successfully updated. This Knowledge Script always raises an event if the job does not run successfully. If enabled, you can configure the severity level of the event. The default is y.
Event severity when update succeeds or fails	Set the event severity level, from 1 to 40, to reflect the importance when the job successfully complete or when the job fails. The default is 5.
Security level	Select the security level you want the managed UNIX computer to use: • **0 - Cleartext** if you want all communications between the agent and the management server to be in cleartext and is not encrypted. This option is best for closed network environments, testing, or troubleshooting communication issues. • **1 - Encryption** if you want all communications between the agent and the management server to be encrypted. • **2 - Encryption and authentication** if you want the management server to be authenticated before sending and receiving encrypted communication. Keep in mind that, for a single repository, all managed UNIX clients must use the same security level setting. Any time you update security, you must do so for all of your UNIX agents. If you cannot update all of your UNIX agents at once, the management server cannot communicate with those agents and the interruption in communication might result in missing critical events or data. Therefore, you should plan any change to the security level carefully to minimize the chance of communication failures. The default is 0 - Cleartext.

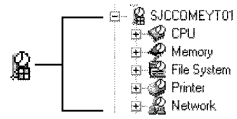
8.5 SchedMaint

Use this Knowledge Script to schedule a maintenance period for a specific application or for all resources on a managed client computer. During the maintenance period, regularly scheduled AppManager jobs do not run. You can specify the jobs you want to prevent from running by Knowledge Script category, or you can prevent all jobs from running on a server. For example, if you are planning routine maintenance on an Apache Server, you might want to block only the ApacheUNIX Knowledge Script jobs but if you are taking a computer offline to upgrade hardware or replace parts, you might want to prevent all jobs from running temporarily.

The maintenance icon , indicates that a computer is in unscheduled maintenance mode (machine maintenance mode) or that all resources on a computer are in scheduled maintenance mode (that is, all jobs are blocked). When you see this icon, AppManager has temporarily stopped monitoring the computer.



If **all jobs** for a computer are blocked, because of scheduled maintenance or because the computer has been selected for unscheduled maintenance, the maintenance icon is displayed for all resources.



If a **particular category** is blocked for scheduled maintenance, the schedule icon is displayed for all resources on the computer. Although the icon is displayed for all resources, only jobs for the specified category are blocked. You need to review the script properties to determine the specific server jobs that are blocked.

You define the start and end time for the scheduled maintenance period on the **Schedule** tab when you set the job properties. Jobs resume running on the managed computer when the maintenance period expires.

8.5.1 Resource Object

Any UNIX computer

8.5.2 Default Schedule

By default, this script set to run **Daily** for a managed computer. However, you should use AppManager's scheduling capabilities found on the **Schedule** tab to set a schedule appropriate to your environment and maintenance needs. For more information about scheduling, see "Example of How this Script Is Used" on page 333.

8.5.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Knowledge Script category to block (for example, ORACLEUNIX)	Enter the Knowledge Script category for the jobs you do not want to run during a maintenance period (for example, NetBackupUNIX to block only NetBackupUNIX Knowledge Script jobs). You must specify the full category name, but the name is not case-sensitive. You can specify either a single category or an asterisk (*) for all jobs on a target computer. The default is all jobs (*).

Description	How to Set It
Raise event if schedule successfully implemented? (y/n)	Set to **y** to raise an event indicating the success of the operation. The default is n.
Event severity when schedule successfully implemented	Set the event severity level, from 1 to 40, to reflect the importance of the event. If you set this Knowledge Script to raise an event when the job succeeds, set the event severity level for a successful operation. The default is 25.
Event severity when schedule implementation fails	Set the event severity level, from 1 to 40, to reflect the importance of the event. The default is 5.

8.5.4 Example of How this Script Is Used

In many environments, specific application servers have regularly scheduled periods when they are brought down by administrators so administrative tasks can be performed.

For example, an organization has have 20 Web servers that are shut once a month at 10 p.m. This interruption causes all of the AppManager jobs that are not explicitly stopped to error out and forces the administrator to restart the jobs manually when the servers are brought back online.

With this Knowledge Script, administrators can define a specific schedule for temporarily blocking jobs during a planned maintenance period.

For example, you can use the **Schedule** tab to define a monthly schedule that blocks jobs on the last weekend of each month during a two-hour window. Jobs that would normally run during this period, starting at 9:55 PM and ending at 11:55 PM are temporarily inactive. In this example, the actual maintenance period is short (just two hours once a month), but AppManager's scheduling capabilities provide enough flexibility for you to define a maintenance schedule that best meets your needs.

On the **Values** tab, you can identify a specific Knowledge Script category to block such as ApacheUNIX or you can use the default (*) to block all of the jobs if the computers are going to be physically shut down. For example, to block all of the UNIX Knowledge Script jobs you might set the **Knowledge Script category to block** parameter to `Unix`.

At 9:55 PM local time (on the computer where the job is running), the maintenance period begins and all UNIX Knowledge Script jobs running on the target computers become inactive to allow for the scheduled maintenance. At 11:55 local time, the maintenance period expires and the jobs resume running at their regularly scheduled intervals.

8.6 SetPrimaryMS

Use this Knowledge Script to set or change the primary or secondary management server for version 7.0.1 or earlier UNIX agents, or to change the port number of the primary or secondary management server.

To change the management server designation for a version 7.1 UNIX agent, use NetIQ UNIX agent Manager. For more information, see the UNIX Agent Manager online Help.

This Knowledge Script allows you to explicitly designate a primary and a secondary management server and therefore explicitly control the communication between the managed UNIX clients and the management servers authorized to communicate with those managed clients. This Knowledge Script allows you to specifically assign a single primary management server for specified UNIX agents. Once you have identified a primary management server, the UNIX agent sends all information to that computer.

To help ensure communication is maintained even if the primary management server goes down, you can also use this Knowledge Script to explicitly designate a secondary or backup management server for the managed client. If the primary management server for the managed client fails, the backup management server takes over communication with the managed client until communication with the primary management server is restored.

If the target UNIX agent computer does not have the specified management server defined in the configuration file (`NqmComms.xml`), the agent adds it to the configuration file and then sets the flags according to the value you set for the **Select the management server operation to perform** parameter.

If you run the job from a management server computer, be aware that the job can only set a primary or backup management server when the specified management server is associated with the same repository. For example, Management Server A for Repository 1 cannot specify that Management Server B for Repository 2 should now become the primary or backup management server for Repository 1.

NOTE: When you install the UNIX agent, you implicitly establish a primary management server and can use this Knowledge Script to change the primary management server or designate a secondary management server. We recommend, however, that you explicitly designate the primary and secondary management servers by running this Knowledge Script twice.

The first time you run the job, you should identify the primary management server. After you receive notification that setting the management server has been successful, you can run the script a second time to set the secondary management server. You can also use this Knowledge Script to remove a management server for a target UNIX agent.

8.6.1 Resource Object

UNIX computer icon

8.6.2 Default Schedule

By default, this script is **only run once for each computer**.

8.6.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event if job succeeds? (y/n)	Set to **y** to raise events that indicate whether the management server configuration succeeded. The default is y.
Event if job fails? (y/n)	Set to **y** to raise events that indicate whether the management server configuration was not successful. When this parameter is enabled, a failure in the configuration of the management server raises a severe event. The default is y.
Management server hostname or IP address	Enter the name or IP address of the management server you want to set as a primary or secondary management server or that you want to remove for a UNIX agent. Keep in mind that you should set the primary management server first, then rerun this script to set the secondary management server or to make any changes to either the primary or secondary management server. **NOTE:** Although you can specify the management server by hostname or IP address, based on how you have your site configured, the event detail message always identifies the computer by IP address.
Management server operation to perform	Select the appropriate option for the management server you have specified. • **Set primary management server** to change the primary management server • **Set secondary management server** to change the backup management server • **Unset management server** to remove the specified management server as a valid management server for the target computer **NOTE:** If the target computer does not have the specified management server defined in its configuration file (`NqmComms.xml`), the UNIX agent adds it to the configuration file and then sets the flags according to the value you set here. The default is Set primary.
Port number for the management server	Type the port number you want to use on the management server for communications from UNIX agents. The port number should be the same port you specified when you installed the management server or the port number you have set for the `UNIX port` in the management server registry. **NOTE:** If you have changed the port number for UNIX agents in the management server registry, run this script to set the new port number on your UNIX agents, then restart the management server to restore communication. The default is `9001`.
Event severity when job succeeds	Set the event severity level, from 1 to 40, to indicate the importance of the event when setting the management server succeeds. The default severity level is 25.
Event severity when job fails	Set the event severity level, from 1 to 40, to indicate the importance of the event when setting the management server fails. The default severity level is 5.

8.6.4 Example of How this Script Is Used

When you establish a primary management server for a managed client, that management server becomes the only management server that the managed client communicates with for a single repository/management server configuration. A secondary or backup management server can also be defined for each managed client in case the primary management server fails. The secondary management server only communicates with the managed client when the primary management server is unavailable.

When communication with the primary management server resumes, the managed client resumes exclusive communication with the primary management server.

Because a multiple management server environment is chiefly intended for failover functionality (to provide an alternative management server if the primary management server fails), each managed client can have one primary management server and one backup management server for each repository.

9 AM Health Knowledge Scripts

The AppManager Self Monitoring module, also known as AM Health, provides Knowledge Scripts for monitoring the health and availability of AppManager components.

From the Knowledge Script view of Control Center, you can access more information about any NetIQ-supported Knowledge Script by selecting it and clicking **Help**. In the Operator Console, click any Knowledge Script in the Knowledge Script pane and press **F1**.

Knowledge Script	What It Does
AgentDown	Monitors the health of AppManager agents and raises events when agents are down or unavailable.
CCComponentsHealth	Monitors the health and availability of SQL Server resources associated with Control Center components.
HeartbeatUNIX	Monitors the AppManager agent heartbeat in a UNIX or Linux environment.
HeartbeatWin	Monitors the AppManager agent heartbeat in a Microsoft Windows environment.
QDBComponentsHealth	Monitors the health and availability of SQL Server resources associated with the AppManager repository (QDB) and the management server.
Recommended Knowledge Script Groups	Perform essential monitoring of AppManager components. These groups include AMHealth_HealthCheckAMAgentComponents and AMHealth_HealthCheckAMCoreComponents

9.1 AgentDown

Use this Knowledge Script to monitor the health of AppManager agents, raise events when agents are down or unavailable, and generate actions as appropriate. This script does not raise events when AppManager agents are up (running) and available. You can set the event severity for an individual agent, or you can override the severity with this script to specify one severity for any agent with issues.

This script complements the AMHealth_HeartbeatWin and AMHealth_HeartbeatUNIX Knowledge Scripts, but it is different in the following important ways:

- Run the AMHealth_AgentDown Knowledge Script on management servers. This script queries information from the AppManager repository (QDB) to obtain agent status, which is populated by the AMHealth_Heartbeat jobs. As a result, you must run AMHealth_Heartbeat jobs on your agents as well as run an AMHealth_AgentDown job on your management server. One AgentDown job can monitor all agents for which the heartbeat is running. The AMHealth_AgentDown script supports the execution of actions.
- Run the relevant AMHealth_HeartBeat Knowledge Scripts on the agents you wish to monitor. Select **Yes** for either the **Raise an event if the agent heartbeat fails?** parameter or the **Generate heartbeat data?** parameter, or select both parameters. The AMHealth_Heartbeat scripts do not support the execution of actions.

You can run this script on multiple management servers for redundancy. In this situation, each AMHealth_AgentDown job raises duplicate events and generates duplicate actions.

If you stop and restart AMHealth_HeartbeatWin and AMHealth_HeartbeatUNIX jobs, the AMHealth_AgentDown job might raise duplicate events.

9.1.1 Prerequisites

- AppManager version 8.0.2 or later on the QDB and management server
- AppManager version 8.0 or later on the AppManager agent
- AMHealth version 8.0.113.0 or later on the QDB and all console computers

9.1.2 Configuring Security Manager for AMHealth_AgentDown

The AMHealth_AgentDown Knowledge Script requires credentials to connect to the AppManager Repository (QDB). If the QDB uses SQL authentication, create the following entry in Security Manager on the **Custom** tab:

Field	Description
Label	`AMH$SQL`
Sub-label	SQL user name with authority to access the QDB.
Value 1	SQL password for the user name entered in the **Sub-Label** field.
Extended application support	Encrypts the user name and password in Security Manager. This option must be selected.

9.1.3 Resource Objects

Management server

9.1.4 Default Schedule

The default interval for this script is **every 5 minutes**.

9.1.5 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Always consolidate events?	Select **Yes** to raise a single event for all down agents, regardless of how many agents are down. The default is Yes. Select **No** to use the **Raise consolidated event if X percent of agents are down** setting in Control Center for determining whether to raise a single event for all down agents, or one event per down agent. You can edit the Health Check settings in Control Center by clicking **Options** on the **Main** tab, and then clicking **Health Check**.
Use plain text for the event detail?	Select **Yes** to format event messages for down agents using plain text, which is recommended for email notifications. Select **No** to format event messages for down agents using XML. The default is Yes. Regardless of what you enter for this parameter, if the Action_SMTPMail action Knowledge Script is associated with an AMHealth_AgentDown job, the email displays in plain text.
SQL logon	Specify the SQL Server user name required for access to the AppManager repository (QDB). This setting requires an entry in AppManager Security Manager, as described in "Configuring Security Manager for AMHealth_AgentDown" on page 338. Leave this field blank for Windows Authentication.
Override agent down severity?	Select **Yes** to use this script to specify the event severity when an agent is down. If you select No, AppManager uses the event severity for a down agent that is specified by the AMHealth_HeartbeatWin and AMHealth_HeartbeatUNIX Knowledge Scripts. The default is Yes.To prevent the duplication of agent-down events generated by both the AMHealth_Heartbeat and AMHealth_AgentDown jobs, select **Yes** and set the **Severity for override** parameter in this script to 40. Next, choose *one* of the following options: • In the Operator Console, open the **File** menu and select **Preferences**. On the **Repository** tab, click **Event**. Select **Automatically close event when severity is greater than X** and set it to 39. Using this option, events raised by AgentDown immediately go to Closed state, but actions are still executed. • On the Management Server, open the registry and navigate to `\SOFTWARE\..\NetIQ\AppManager\4.0\NetIQmc\Config`, and set the `NoEventSev` registry key to 40. Then stop and restart the NetIQMC service. With this option, the AMHealth_AgentDown job does not raise events, but the script still executes actions.

Parameter	How to Set It
Severity for override	Set the event severity level, from 1 to 40, to indicate the importance of an event when an agent is detected as being down or unavailable. This parameter is ignored if you do not select the **Override agent down severity?** parameter. The default is 40.
Severity for unexpected error	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the AMHealth_AgentDown Knowledge Script fails to connect to the QDB, or fails in any other unexpected way. The default is 35.

9.2 CCComponentsHealth

Use this Knowledge Script to monitor the health and availability of Microsoft SQL Server resources associated with AppManager Control Center components. These components include the Cache Manager, the Command Queue Service (CQS), deployment services, and the Control Center repository (NQCCDB).

This script monitors the percentage of database space and log space used, the amount of time required for a SQL command or query to execute, and the status of AppManager scheduled tasks, which are SQL Server agent jobs operating on the NQCCDB. This script can restart a service or job that is down.

If the NQCCDB does not have an AppManager agent installed on it, Discovery_AMHealth discovers the NQCCDB components on the server running the Command Queue Service. As a result, the service and database monitoring parameters for this script run remotely. In this situation, you must have sufficient privileges on the service account for the NetIQMC service on the server running the Command Queue Service so that the service account can remotely access the SQL Server service on the NQCCDB to obtain its status.

If the account does not have proper privileges, the script will be unable to access the service status and will report that the SQL Server service is down even when it is not. If you do not have sufficient access for the service account for the NetIQMC service, deselect the *Raise an event if SQL Server services are down* and *Restart SQL Server services that stop unexpectedly* parameters in this script to avoid raising unnecessary events.

This script raises events for the following situations:

- SQL Server services are down or have been restarted.
- SQL Server agent jobs are disabled, missing, or have failed.
- The CQS is down or is not connected to the Control Center repository.
- Control Center Cache Manager errors occur.
- SQL Server queries against the NQCCDB take too long to process.
- Deployment services are down.
- Database or log space is low, and there is insufficient disk space for further growth.

If you do not have an agent installed on the NQCCDB server, the repository component gets discovered on the CQS. If you try to remotely monitor the NQCCDB from the CQS using the CCComponentsHealth script, the script will not be able to obtain the disk information remotely.

As a result, if the repository component is monitored remotely from the CQS by the CCComponentsHealth script, the following NQCCDB component monitoring parameters under the *SQL Server File Size and Growth Settings Monitoring* Event Notification Knowledge Script section will not be available:

- Raise an event if SQL Server maximum file size exceeds available disk space?
- Raise an event if insufficient space available for further file growth?

9.2.1 Resource Objects

- Cache Manager
- CQS
- Deployment services
- Control Center repository

9.2.2 Default Schedule

The default interval for this script is **every 30 minutes**.

9.2.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Event Notification	
Raise an event if SQL Server services are down?	Select **Yes** to raise an event if Control Center SQL Server services are down. The default is Yes. **Tip** Use Action Script for notification, as the Control Center repository will not be available.
Event severity when SQL Server services are down	Set the event severity level, from 1 to 40, to indicate the importance of an event in which SQL Server services are down. The default is 10.
Restart SQL Server services that stop unexpectedly?	Select **Yes** to restart SQL Server services that stop unexpectedly, such as when not as part of scheduled maintenance. The default is Yes.
Raise an event if SQL Server services cannot be restarted?	Select **Yes** to raise an event if SQL Server services cannot be restarted. The default is Yes. **Tip** Use Action Script for notification, as the Control Center repository will not be available.
Event severity when SQL Server services cannot be restarted	Set the event severity, from 1 to 40, to indicate the importance of an event in which SQL Server services cannot be restarted. The default is 5.
Raise an event if SQL Server services are restarted?	Select **Yes** to raise an event if SQL Server services are successfully restarted. The default is Yes.
Event severity when SQL Server services are restarted	Set the event severity level, from 1 to 40, to indicate the importance of an event in which SQL Server services are successfully restarted. The default is 25.

Parameter	How to Set It
Raise an event if Control Center Cache Manager errors occur?	Select **Yes** to raise an event if the Control Center Cache Manager experiences one of the following: • An error related to Microsoft Distributed Transaction Control (MSDTC). • An error with the synchronization of data between Control Center and the QDB repositories that are synchronized to Control Center. • An error from a Control Center SQL Server agent job that has failed. The default is Yes. **NOTE:** Not all Control Center SQL Server Agent jobs are monitored. Only those that are related to Cache Manager are monitored. The following jobs are monitored for errors that affect Cache Manager: • NetIQ CC Manage SQL Jobs NQCCDB • NetIQ CC Hourly Task NQCCDB • NetIQ CC Half-Hourly Task NQCCDB • NetIQ CC Daily Task NQCCDB Cache Manager is a child process of the CQS. Cache Manager runs the Control Center queries on AppManager repository computers to retrieve view information for Control Center s. After the first iteration of the Knowledge Script completes, only new errors generated since the previous iteration will be raised as events.
Event severity when Cache Manager errors occur	Set the event severity, from 1 to 40, to indicate the importance of an event in which Cache Manager experiences errors. The default is 10.
Raise an event if Control Center SQL Server jobs are missing?	Select **Yes** to raise an event if SQL Server jobs are missing. The default is Yes. A missing job is one that might have been deleted or renamed.
Event severity when Control Center SQL Server jobs are missing	Set the event severity, from 1 to 40, to indicate the importance of an event in which SQL Server jobs are missing. The default is 15.
Raise an event if Control Center SQL Server jobs are disabled?	Select **Yes** to raise an event if SQL Server jobs are disabled. The default is Yes.
Event severity when Control Center SQL Server jobs are disabled	Set the event severity, from 1 to 40, to indicate the importance of an event in which SQL Server jobs are disabled. The default is 15.
Enable SQL Server jobs that are disabled?	Select **Yes** to enable, or start, SQL Server jobs that are disabled. The default is No.
Event severity when SQL Server jobs cannot be enabled	Set the event severity, from 1 to 40, to indicate the importance of an event in which disabled SQL Server jobs cannot be enabled, or started. The default is 20.
Raise an event if SQL Server jobs are successfully enabled?	Select **Yes** to raise an event if disabled SQL Server jobs are successfully enabled, or started. The default is No.
Event severity when SQL Server jobs are successfully enabled	Set the event severity level, from 1 to 40, to indicate the importance of an event in which disabled SQL Server jobs are successfully enabled, or started. The default is 20.
Raise an event if a Control Center SQL Server job fails?	Select **Yes** to raise an event if any step in a SQL Server job fails. The default is Yes.

Parameter	How to Set It
Event severity when a Control Center SQL Server job fails	Set the event severity level, from 1 to 40, to indicate the importance of an event in which a SQL Server job fails. The default is 20.
Raise an event if Control Center server disks are fragmented?	Select **Yes** to raise an event if disks on the Control Center server are fragmented. The default is Yes. **Tip** To avoid errors when running this script on a Windows Server 2008 server, disable User Account Control (UAC).
Event severity when disks are fragmented	Set the event severity level, from 1 to 40, to indicate the importance of an event in which disk fragmentation has occurred on the Control Center server. The default is 15.
Raise an event if query process time exceeds threshold?	Select **Yes** to raise an event if the amount of time it takes to process a SQL query exceeds the threshold you set. The default is Yes.
Threshold – Maximum process run time	Specify the maximum length of time it can take SQL Server processes to run before an event is raised. The default is 300 seconds.
Event severity when query process time exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which SQL query processing time exceeds the threshold you set. The default is 10.
Event severity when query process time cannot be retrieved	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the script cannot determine the processing time for SQL queries. Processing time could be prevented from being retrieved if the query fails due to blocking, or if a connection cannot be made to the Control Center QDB SQL Server, which would cause the query to fail. If the query fails, the event will be raised without exception, which would inform users if there was an issue with the Control Center QDB SQL Server. The default is 10.
Raise an event if Deployment services are down?	Select **Yes** to raise an event if Control Center deployment services are down. The default is Yes. The following situations can cause deployment services to be down: • The Control Center server is restarted. • Deployment services took too long to restart. • The connection to the Control Center repository is unavailable. • The proxy server is unavailable.
Event severity when Deployment services are down	Set the event severity level, from 1 to 40, to indicate the importance of an event in which deployment services are down. The default is 10.
Raise an event if unable to retrieve Control Center component information?	Select **Yes** to raise an event if the script does not have the discovery details for the Control Center components, or if the discovery details are empty. The default is Yes.
Event severity when unable to retrieve Control Center component information	Set the event severity level, from 1 to 40, to indicate the importance of an event in which AppManager cannot retrieve Control Center Component information. The default is 10.
NetIQ Control Center Command Queue Service Monitoring	
Raise an event if Command Queue Service is not connected to the Control Center database?	Select **Yes** to raise an event if the Command Queue Service (CQS) is not connected to the Control Center database (`NQCCDB`). The default is Yes. The CQS polls the Command Queue table for queries to run. The Command Queue table stores queries that collect view information based on the criteria defined in Control Center.

Parameter	How to Set It
Event severity when Command Queue Service is not connected to the Control Center database	Set the event severity, from 1 to 40, to indicate the importance of an event in which the CQS is not connected to the Control Center database (NQCCDB). The default is 10.
Raise an event if Command Queue Service is down?	Select **Yes** to raise an event if the CQS is down. The default is Yes.
Event severity when Command Queue Service is down	Set the event severity level, from 1 to 40, to indicate the importance of an event in which CQS is down. The default is 10.
Restart Command Queue Service if the service is down?	Select **Yes** to restart CQS if it is down. The default is Yes.
Raise an event if Command Queue Service is restarted?	Select **Yes** to raise an event if CQS is successfully restarted. The default is Yes.
Event severity when Command Queue Service is restarted	Set the event severity level, from 1 to 40, to indicate the importance of an event in which CQS is successfully restarted. The default is 25.
Raise an event if Command Queue Service cannot be restarted?	Select **Yes** to raise an event if CQS cannot be restarted. The default is Yes.
Event severity when Command Queue Service cannot be restarted	Set the event severity level, from 1 to 40, to indicate the importance of an event in which CQS cannot be restarted. The default is 5.
SQL Server File Size and Growth Settings Monitoring	
Raise an event if insufficient space available for further file growth?	Select **Yes** to raise an event if the amount of available disk space is not enough to allow the file to continue to grow. SQL Server has growth settings on the Database Data and Log files. If the amount of free space on the disk is lower than this growth setting, an event will be raised to keep the files from attempting to grow and causing the SQL Server databases to become corrupted. The default is Yes.
Event severity when available space is insufficient	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the available server space is insufficient. The default is 10.
Raise an event if file growth rate falls below the threshold?	Select **Yes** to raise an event if the growth rate of the database data and log files falls below the threshold you set. If the growth rate is low, the data and log files become fragmented, which negatively impacts performance. **NOTE:** The two threshold parameters (MB and percentage) are evaluated individually depending on whether the database file growth setting is in MB or a percentage. The default is Yes.
Threshold – Minimum growth rate in MB	Specify in megabytes the minimum growth rate of SQL Server files before an event is raised. The default is 256 MB.
Threshold – Minimum growth rate in percentage	Specify as a percentage the minimum growth rate of SQL Server files before an event is raised. The default is 9%.
Event severity when file growth rate falls below the threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the rate of growth of SQL Server files falls below the threshold you set. The default is 10.

Parameter	How to Set It
Raise an event if Autogrowth is not enabled and file usage exceeds the threshold?	Select **Yes** to raise an event if the file usage exceeds the threshold and Autogrowth is not enabled. The default is Yes. The Autogrowth feature allows a database to grow by the amount of space required by a file or a transaction.
Threshold – Maximum file usage with Autogrowth disabled	Specify the maximum amount of file usage with Autogrowth disabled that can occur before an event is raised. The default is 90%.
Event severity when Autogrowth disabled and usage exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the file usage exceeds the threshold and Autogrowth is not enabled. The default is 10.
Raise an event if SQL Server maximum file size exceeds available disk space?	Select **Yes** to raise an event if the maximum SQL file size (`MAXSIZE`) is set to a value greater than the amount of available disk space. The default is No. The `MAXSIZE` value identifies the maximum size to which a SQL Server database can grow.
Event severity when SQL maximum file size exceeds disk space	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the maximum SQL file size is set to a value greater than the amount of available disk space. The default is 15.
Data Collection	
Collect data for database space utilization?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the percentage of database space used on the Control Center server. The default is No.
Collect data for log space utilization?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the percentage of log space used on the Control Center server. The default is No.
Collect data for Command Queue Server connection status?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns **100** if CQS is up and **0** if CQS is down. The default is No. **NOTE:** This script only collects data for the CQS connection status when you run the script on the Control Center database (`NQCCDB`). The script does *not* collect data when you run it on the CQS.
Collect data for SQL Server service status?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns **100** if SQL Server services are up and **0** if SQL Server services are down. The default is No.
Monitoring	
SQL username	Specify the username required to access SQL Server on the Control Center server.
Event severity for a Knowledge Script error	Set the event severity level, from 1 to 40, to indicate the importance of an event in which an unexpected Knowledge Script error occurs. The default is 10.

9.3 HeartbeatUNIX

Use this Knowledge Script to test the heartbeat of the AppManager agent computer running UNIX or Linux. A **heartbeat** is a periodic signal generated by an AppManager agent computer to indicate that it is still running. If an AppManager agent fails to send either data or an event to the QDB within the specified grace period, the AMHealth_HeartbeatUNIX job considers the agent to be offline.

You can set this script to raise an event for the following conditions:

- The heartbeat fails.
- An agent is healthy, such as when the heartbeat returns after failing.
- The agent heartbeat fails a user-specified number of times.

If you use this Knowledge Script with the AppManager Operator Console, you can access the Actions and Advanced tab, but the options on those two tabs will not function.

This script generates data for consolidated events, which can be managed with the Health Check options found in Control Center. To access Health Check, click **Options** on the **Main** tab, and then click **Health Check**. For more information, see the online Help for Health Check.

9.3.1 Resource Objects

UNIX and Linux servers

9.3.2 Default Schedule

The default interval for this script is **every five minutes**.

9.3.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Heartbeat Options	
Raise an event if the agent heartbeat fails?	Select **Yes** to raise an event if the heartbeat for the AppManager agent server stops. The default is Yes.
Event severity when the agent heartbeat fails	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the heartbeat stops. The default is 5.
Raise an event when agent heartbeat restarts?	Select **Yes** to raise an event if the heartbeat starts again after stopping. The default is Yes.
Event severity when the agent heartbeat restarts	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the heartbeat starts again after stopping. The default is 25.
Number of consecutive heartbeat failures before raising an event	Specify the number of times the heartbeat must fail before raising an event. The default is 1.

Parameter	How to Set It
Generate heartbeat data?	Select **Yes** to enable the heartbeat check. If you select Yes and the data point from this job is missing, AppManager raises an event. If you select No, the heartbeat check will not look for the data point from this job. The default is Yes.
Heartbeat Investigation Steps (Used by Management Server)	AppManager performs the following steps only if the heartbeat event or the heartbeat data is missing.
Attempt to contact agent computer by ICMP ping?	Select **Yes** to send an ICMP ping request to the agent computer. If AppManager cannot contact an agent with an ICMP ping, the agent computer might have been shut down or disconnected from the network, or a firewall is blocking the ICMP communication. The default is Yes.
Perform tracert diagnostic if ICMP ping fails?	Select **Yes** to run a tracert (traceroute) diagnostic test if the ping request fails. The default is Yes. A traceroute test helps you troubleshoot network routing problems that can block ICMP traffic. This script raises an event if the tracert fails.

9.4 HeartbeatWin

Use this Knowledge Script to test the heartbeat of the AppManager Windows agent computer. A **heartbeat** is a periodic signal generated by an AppManager agent computer to indicate that it is still running. If an AppManager agent fails to send either data or an event to the QDB within the specified grace period, the AMHealth_HeartbeatWin job considers the agent to be offline.

This script raises events if the heartbeat for the agent computer stops or restarts, and it generates a data point about the heartbeat events. You can also use this script to track whether jobs finish in the expected time frame, or if they exceed the maximum run time.

You can set this script to raise an event for the following conditions:

- Heartbeat fails
- An agent is healthy, such as when the heartbeat returns after failing
- The agent heartbeat fails a user-specified number of times
- Jobs take longer than expected to execute
- Jobs exceed maximum run time
- No jobs are found

If an agent computer is offline, you can specify that the management server take additional steps to diagnose the level of non-connectivity that exists between the agent and the QDB.

If you use this Knowledge Script with the AppManager Operator Console, you can access the Actions and Advanced tab, but the options on those two tabs will not function.

This script generates data for consolidated events, which can be managed with the Health Check options found in Control Center. To access Health Check, click **Options** on the **Main** tab, and then click **Health Check**. For more information, see the online Help for Health Check.

9.4.1 Resource Objects

Windows servers

9.4.2 Default Schedule

The default interval for this script is **every five minutes**.

9.4.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Heartbeat Options	

Parameter	How to Set It
Raise an event if the agent heartbeat fails?	Select **Yes** to raise an event for the selected agent if the agent is detected as having failed the heartbeat. The default is Yes. If several agents fail the heartbeat at the same time, the script raises a single event for those agents, and the event message lists all the offline agents. By default, you receive a single, consolidated event instead of multiple, individual events when 30% of the agents go offline. You can change this setting in Control Center by clicking **Options** on the **Main** tab, and then clicking **Health Check**. If you set the *Monitor individual jobs?* parameter in this script to Yes, you can control the severity of all heartbeat failure events using the *Event severity when the agent heartbeat fails* parameter instead of using the same severity for all consolidated events.
Event severity when the agent heartbeat fails	Set the event severity level, from 1 to 40, to indicate the importance of an event in which an agent failed the heartbeat. The default is 5.
Raise an event when agent heartbeat restarts?	Select **Yes** to raise an event if the heartbeat starts again after stopping. The default is Yes.
Event severity when the agent heartbeat restarts	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the heartbeat starts again after stopping. The default is 25.
Number of consecutive heartbeat failures before raising an event	Specify the number of times the heartbeat must fail before raising an event. The default is 2.
Generate heartbeat data?	Select **Yes** to enable the heartbeat check. If you select Yes and the data point from this job is missing, AppManager raises an event. If you select No, the heartbeat check will not look for the data point from this job. The default is Yes.
Job Monitoring Options	
Monitor individual jobs?	Select **Yes** to monitor *all* jobs running on the agent that came from the same QDB as the heartbeat job. If you select No, the heartbeat job simply sends the heartbeat event and data according to the heartbeat-related parameters you set for this Knowledge Script. The default is Yes.
Raise an event if jobs take longer than average to execute?	Select **Yes** to raise an event that lists all jobs that are taking longer to execute than their average execution time. The agent stores a list of the average times jobs take to execute. The default is Yes.
Ignore jobs running for less than this amount of time	If you want to ignore jobs that are running for certain length of time, specify the running time for jobs that will be ignored. The default is 30 seconds.
Grace period	Specify a number to represent the grace period for job execution. The grace period is a multiple of the average time a job takes to execute. The agent stores a list of the average times jobs take to execute. For example, if you specified a grace period of 5, this script would take that value and multiply it by the average time a job takes to execute. If a job took one second to execute on average, the grace period would be 5 seconds. If the job takes longer than 5 seconds, the script raises an event. The default grace period is 5.
Event severity when jobs take longer than average to execute	Specify the event severity, from 1 to 40, to indicate the importance of an event in which the execution time for Knowledge Script jobs is longer than the average execution time for that job. The default is 5.
Raise an event if jobs take longer than their schedule to execute?	Select **Yes** to raise an event that lists all jobs that are taking longer to execute than their scheduled time to execute. The scheduled time is how often the job is set to run, such as every five minutes. The default is Yes.

Parameter	How to Set It
Event severity when jobs take longer than their schedule to execute	Specify the event severity, from 1 to 40, to indicate the importance of an event in which the execution time for a Knowledge Script job is longer than the script's schedule. The default is 5.
Raise an event if job exceeds maximum job run time?	Select **Yes** to raise an event if the run time for a Knowledge Script job exceeds the *Maximum job run time* threshold. The default is Yes.
List of Knowledge Scripts to skip "Maximum job run time" check	Provide a comma-separated list of the Knowledge Scripts that you do not want to compare to the *Maximum job run time* threshold.
Maximum job run time	Specify the maximum number of seconds a Knowledge Script job can run before an event is raised. The default is 180 seconds.
Event severity when job exceeds maximum job run time	Set the event severity, from 1 to 40, to indicate the importance of an event in which the run time for a Knowledge Script job exceeds the *Maximum job run time* threshold. The default is 5.
Raise an event if no jobs found?	Select **Yes** to raise an event if no Knowledge Script jobs are running. The default is No.
Event severity when no jobs found	Set the event severity level, from 1 to 40, to indicate the importance of an event in which no Knowledge Script jobs are running. The default is 35.
Timeout when processing jobs	Specify how long AppManager should wait for the agent to process jobs before assuming the agent either will not respond or has timed out. Use this parameter to monitor agents that are consistently taking longer than expected to respond. If the agent does not respond before your specified timeout value, AppManager raises an event stating that it was unable to process this command and suggesting you increase the timeout value. The event might also include data about a Windows error, if one was generated. The default timeout is 10 seconds.
Use XML formatting in event message?	Select **Yes** to format event messages in XML. The default is Yes. Leave this parameter No to format event detail messages in plain text. Events formatted in XML display results in tables. Events in plain text display results in rows of unformatted text.
Knowledge Script Options	
Event severity when unexpected error occurs	Set the event severity level, from 1 to 40, to indicate the importance of an event in which this Knowledge Script job fails or any other unexpected event occurs. The default is 35.
Heartbeat Investigation Steps (Used by Management Server)	AppManager performs the following steps only if the heartbeat event or the heartbeat data is missing.
Attempt to contact agent computer by ICMP ping?	Select **Yes** to send an ICMP ping request to the agent computer. If AppManager cannot contact an agent with an ICMP ping, the agent computer might have been shut down or disconnected from the network, or a firewall is blocking the ICMP communication.
Perform tracert diagnostic if ICMP ping fails?	Select **Yes** to run a tracert (traceroute) diagnostic test if the ping request fails. The default is Yes. A traceroute test helps you troubleshoot network routing problems that can block ICMP traffic. This script raises an event if the tracert fails.

Parameter	How to Set It
Connect to agent NetIQmc port if ICMP ping succeeds?	Select **Yes** to attempt a connection to the `NetIQmc` port on the agent computer. The default is Yes. The connection is attempted only if the ping attempt succeeds. This script raises an event if the ping fails.
Use RPC to probe agent if port check succeeds?	Select **Yes** to send a Remote Procedure Call (RPC) to the agent computer. The default is Yes. The RPC is sent only if the port connection succeeds. This script raises an event if the RPC probe fails.
Test agent computer registry if RPC probe succeeds?	Select **Yes** to allow the management server to attempt to use the Remote Registry Service to connect to the Windows Registry on the agent computer. The connection is attempted only if the RPC probe succeeds. The management server must have sufficient privileges to connect to the Registry. The default is No. This script raises an event if the management server cannot connect to the Registry.
Check status of agent services if registry test succeeds?	Select **Yes** to allow the management server to verify whether the NetIQ agent services, `NetIQccm` and `NetIQmc`, are running. This test is attempted only if the registry test succeeds. The management server must have sufficient privileges to access the agent services. The default is No. This script raises an event if the agent services are up or down.

9.5 QDBComponentsHealth

Use this Knowledge Script to monitor the health of NetIQ AppManager repository (QDB) and management server components.

This script monitors SQL Server resources associated with the QDB, including the percentage of database space and log space used, the time taken for a SQL command or query to execute, and the status of AppManager scheduled tasks. If a service or job is down, this script can restart it.

If the QDB does not have an AppManager agent installed on it, Discovery_AMHealth discovers the QDB components on the management server. As a result, the service and database monitoring parameters for this script run remotely. In this situation, you must have sufficient privileges on the service account for the NetIQMC service on the management server so that the service account can remotely access the SQL Server service on the QDB to obtain its status.

If the account does not have proper privileges, the script will be unable to access the service status and will report that the SQL Server service is down even when it is not. If you do not have sufficient access for the service account for the NetIQMC service, deselect the *Raise an event if SQL Server services are down* and *Restart SQL Server services that stop unexpectedly* parameters in this script to avoid raising unnecessary events.

You can set this script to raise an event for the following conditions:

- SQL Server services are down or have been restarted.
- SQL Server agent jobs are disabled, missing, or have failed.
- Database or log space is low.
- The management server isn't connected to the QDB database.
- The management server service is down.
- SQL Server queries against the QDB are taking too long to process.
- Database or log space is low, and there is insufficient disk space for further growth.

When monitoring management server performance, QDBComponentsHealth does not use the standard method of creating events through the management server, because the problem being detected might prevent events from being generated through the management server. As a result, this script generates events for these conditions directly in the QDB, and Action scripts will not operate with certain QDBComponentsHealth parameters to generate actions when the conditions occur. Because these events are generated directly in the QDB, event collapsing is always enabled for these events, and it cannot be turned off.

The following QDBComponentsHealth parameters related to management server monitoring will not generate actions:

- Raise an event if the management server service is down?
- Raise an event if the management server service fails to restart?
- Raise an event if the management server service restarts successfully?
- Raise an event if the management server service is not connected to the QDB?
- Raise an event if data map file usage exceeds threshold?
- Raise an event if event map file usage exceeds threshold?
- Raise an event if job map file usage exceeds threshold?

If you do not have an agent installed on the QDB server, the repository component gets discovered on the management server. If you try to remotely monitor the QDB from the management server using the QDBComponentsHealth script, the script will not be able to obtain the disk information remotely.

As a result, if the repository component is monitored remotely from the management server by the QDBComponentsHealth script, the following QDB component monitoring parameters under the *SQL Server File Size and Growth Settings Monitoring* Event Notification Knowledge Script section will not be available:

- Raise an event if insufficient space available for further file growth?
- Raise an event if SQL Server maximum file size exceeds available disk space?

9.5.1 Resource Objects

- AppManager repository (QDB) server
- management server

9.5.2 Default Schedule

The default interval for this script is **every thirty minutes**.

9.5.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Event Notification	
Raise an event if SQL Server services are down?	Select **Yes** to raise an event if SQL Server services are down. The default is Yes. **Tip** Use Action Script for notification, as the QDB will not be available.
Event severity when a SQL Server service is down	Set the event severity level, from 1 to 40, to indicate the importance of an event in which a SQL Server service is down. The default is 5.
Restart SQL Server services if the services are stopped unexpectedly?	Select **Yes** to restart the SQL Server services if the services stop unexpectedly. The default is Yes.
Raise an event if a SQL Server service restart fails?	Select **Yes** to raise an event if a SQL Server service fails to restart. The default is Yes. **Tip** Use Action Script for notification, as the QDB will not be available.
Event severity if a SQL Server service fails to restart	Set the event severity level, from 1 to 40, to indicate the importance of an event in which a SQL Server service fails to restart. The default is 5.
Raise an event if a SQL Server service restart succeeds?	Select **Yes** to raise an event if a SQL Server service restart succeeds. The default is Yes.
Event severity if a SQL Server service restarts successfully	Set the event severity level, from 1 to 40, to indicate the importance of an event in which a SQL Server service restarts successfully. The default is 30.

Parameter	How to Set It
Raise an event if the Management Server service is not connected to the QDB?	Select **Yes** to raise an event if the management server service is not connected to the QDB. The default is Yes.
Event severity when the Management Server service is not connected	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the management server service is not connected. The default is 5.
Raise an event if the QDB SQL Server agent jobs are missing?	Select **Yes** to raise an event if the QDB SQL Server agent jobs are missing. The default is Yes.
Event severity for missing QDB SQL Server agent jobs	Set the event severity level, from 1 to 40, to indicate the importance of an event in which QDB SQL Server agent jobs are missing. The default is 15.
Raise an event if QDB SQL Server agent jobs are disabled?	Select **Yes** to raise an event if QDB SQL Server agent jobs are disabled. The default is Yes.
Event severity for disabled QDB SQL Server agent jobs	Set the event severity level, from 1 to 40, to indicate the importance of an event in which QDB SQL Server agent jobs are disabled. The default is 15.
Enable QDB SQL Server agent jobs if they are disabled?	Select **Yes** to enable QDB SQL Server agent jobs if they are disabled The default is No.
Event severity when the attempt to enable QDB SQL Server agent job fails	Set the event severity level, from 1 to 40, to indicate the importance of an event in which an attempt to enable QDB SQL Server agent job fails. The default is 15.
Raise an event if attempt to enable QDB SQL Server agent job succeeds?	Select **Yes** to raise an event if the attempt to enable the QDB SQL Server agent job succeeds. The default is No.
Event severity when attempt to enable QDB SQL Server agent job succeeds	Set the event severity level, from 1 to 40, to indicate the importance of an event in which an attempt to enable the QDB SQL Server agent job succeeds. The default is 20.
Raise an event if a QDB SQL Server agent job fails?	Select **Yes** to raise an event if a QDB SQL Server agent job fails. The default is Yes.
Event severity when a QDB SQL Server job fails	Set the event severity level, from 1 to 40, to indicate the importance of an event in which a QDB SQL Server job fails. The default is 20.
Raise an event if QDB disks are fragmented?	Select **Yes** to raise an event if AppManager detects QDB disk fragmentation. The default is unselected. **Tip** To avoid errors when running this script on a Windows Server 2008 server, disable User Account Control (UAC).
Event severity for QDB disk fragmentation	Set the event severity level, from 1 to 40, to indicate the importance of an event in which a disk is fragmented. The default is 15.
Raise an event if the query process time exceeds threshold?	Select **Yes** to raise an event if the query process time exceeds threshold. The default is Yes.
Threshold – Maximum process run time	Specify the longest process run time allowed before an event is raised. The default is 300 seconds.
Event severity when query process time exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the query process time exceeds the threshold you set. The default is 5.
Event severity when attempt to retrieve query process time fails	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the attempt to retrieve query process time fails. The default is 10.

Parameter	How to Set It
Raise an event if unable to retrieve QDB component information?	Select **Yes** to raise an event if AppManager is unable to retrieve QDB component information. The default is Yes.
Event severity when unable to connect to retrieve QDB component information	Set the event severity level, from 1 to 40, to indicate the importance of an event in which AppManager is unable to connect to retrieve QDB component information. The default is 10.
Management Server Performance Monitoring	
Raise an event if the Management Server map file is not enabled?	Select **Yes** to raise an event if the management server map file is not enabled. The default is Yes.
Threshold – Current map file size	Specify the current map file size. If the map file size is too small, the management server performance will not be optimal in larger environments. The default is 5 MB.
Event severity if map file is not enabled	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the map file is not enabled. The default is 15.
Raise an event if data map file usage exceeds threshold?	Select **Yes** to raise an event if the data map file usage exceeds the threshold you set. The default is Yes.
Threshold – Maximum data map file usage	Specify the highest level of data map file usage that can occur before an event is raised. The default is 80%.
Event severity when data map file usage exceeds the threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the data map file usage exceeds the threshold you set. The default is 15.
Raise an event if event map file usage exceeds threshold?	Select **Yes** to raise an event if the event map file usage exceeds the threshold you set. The default is Yes.
Threshold – Maximum event map file utilization	Specify the highest level of event map file utilization that can occur before an event is raised. The default is 80%.
Event severity when event map file utilization exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the event map file utilization exceeds the threshold you set. The default is 15.
Raise an event if job map file usage exceeds threshold?	Select **Yes** to raise an event if the job map file usage exceeds the threshold you set. The default is Yes.
Threshold – Maximum job map file utilization	Specify the highest level of job map file utilization before an event is raised. The default is 80%.
Event severity when job map file usage exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the job map file usage exceeds the threshold you set. The default is 15.
Monitoring SQL Server File Size and Growth Settings	
Raise an event if insufficient space available for further file growth?	Select **Yes** to raise an event if there is not enough space for additional file growth on the SQL Server. The default is Yes.
Event severity for insufficient space	Set the event severity level, from 1 to 40, to indicate the importance of an event in which there is not enough space for additional file growth on the SQL Server. The default is 10.
Raise an event if SQL Server file growth rate is lower than the threshold?	Select **Yes** to raise an event if the SQL Server file growth rate is lower than the threshold you set. The default is Yes.
Threshold – Minimum growth rate in MB	Specify the lowest possible growth rate for the SQL Server in MB. The default is 256 MB.

Parameter	How to Set It
Threshold – Minimum growth rate as a percentage	Specify the lowest possible growth rate for the SQL Server as a percentage. The default is 9%.
Event severity when file growth rate is lower than the threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the file growth rate is lower than the threshold you set. The default is 10.
Raise an event if Autogrowth is not enabled and file utilization exceeds the threshold?	Select **Yes** to raise an event if Autogrowth is not enabled, and file utilization exceeds the threshold you set. The default is Yes.
Threshold – Maximum file utilization with Autogrowth disabled	Specify the highest percentage of file utilization with Autogrowth disabled before an event is raised. The default is 90%.
Event severity if Autogrowth disabled and usage exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which usage exceeds the threshold and Autogrowth is disabled. The default is 10.
Raise an event if SQL Server maximum file size exceeds available disk space?	Select **Yes** to raise an event if the SQL Server maximum file size exceeds the available disk space. The default is Yes.
Event severity when SQL Server file size exceeds disk space	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the SQL Server file size exceeds the available disk space. The default is 15.
Monitoring the Management Server Service	
Raise an event if the Management Server service is down?	Select **Yes** to raise an event if the management server service is down. The default is Yes. **NOTE:** AppManager cannot create an event for this if the management server is down.
Event severity if the Management Server service is down	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the management server service is down The default is 10.
Restart the Management Server service if the service is down?	Select **Yes** if you want to restart the management server service if the service is down. The default is Yes.
Raise an event if the Management Server service restarts successfully?	Select **Yes** to raise an event if the management server service restarts successfully. The default is Yes. **NOTE:** AppManager cannot create an event for this if the management server is down.
Event severity if the Management Server service restarts successfully	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the management server service restarts successfully. The default is 25.
Raise an event if the Management Server service fails to restart?	Select **Yes** to raise an event if the management server service fails to restart. The default is Yes. **NOTE:** AppManager creates an event directly in the QDB if the management server fails to restart.
Event severity if the Management Server service fails to restart	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the management server service fails to restart. The default is 5.
Raise an event if agents are not FIPS- compliant?	Select **Yes** to raise an event if the agents are not FIPS-compliant. The default is Yes.
Event severity when agents are not FIPS-compliant	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the agents are not FIPS-compliant. The default is 10.

Parameter	How to Set It
Data Collection	
Collect data for database space utilization?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the percentage of the database data file currently being used. The default is No.
Collect data for log space utilization?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the percentage of the database log file currently being used. The default is No.
Collect data for Management Server connection status?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns 100 if the management server is connected to the repository and 0 if the management server is not connected. The default is No.
Collect data for SQL Server service status?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns 100 if the SQL Server service is up and 0 if the service is down. The default is No.
Collect data for Management Server data map file utilization?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the percentage of the management server data map file currently being utilized. The default is No.
Collect data for Management Server event map file utilization?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the percentage of the management server event map file currently being utilized. The default is No.
Collect data for Management Server job map file utilization?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the percentage of the management server job map file currently being utilized. The default is No.
Monitoring	
SQL username	Specify the user name required to access SQL Server on the Control Center server. The SQL or Windows user must have at least Server Administrator rights in SQL Server.
Event severity for a Knowledge Script error	Set the event severity level, from 1 to 40, to indicate the importance of an event in which an unexpected Knowledge Script error occurs. The default is 10.

9.6 Recommended Knowledge Script Groups

You can find the AMHealth Knowledge Script Groups (KSGs) on the RECOMMENDED tab of the Knowledge Script pane in the Operator Console.

All the scripts in the KSGs have their parameters set to recommended values. To run all of the recommended scripts in a KSG at one time, click the RECOMMENDED tab, and then run the KSG on an AppManager resource.

The AMHealth KSGs enable a "best practices" usage for monitoring your AppManager environment. You can use these KSGs with AppManager monitoring policies. A monitoring policy lets you efficiently and consistently monitor all the resources in your environment using a set of preconfigured Knowledge Scripts. For more information, see "About Policy-Based Monitoring" in the AppManager Help.

A KSG is composed of a subset of a module's Knowledge Scripts. The script that belongs to a KSG is a different copy of the original script you access from the AMHealth tab. If you modify a script that belongs to a KSG, the parameter settings of the original script in the AMHealth tab are not affected.

In some cases, default script parameter settings are different when the script is deployed as part of a KSG, as opposed to when it is deployed alone. The default settings of a script within a group depend on its monitoring purpose within the larger group, and on the intended monitoring scope of that group.

If you modify or remove a script associated with the AMHealth KSG and want to restore it to its original form, you can reinstall the AppManager Self Monitoring module on the repository computer.

9.6.1 AMHealth_HealthCheckAMAgentComponents Recommended KSG

The following Knowledge Scripts are members of the AMHealth_HealthCheckAMAgentComponents recommended KSG:

- HeartbeatUNIX
- HeartbeatWin

This KSG is applied as a monitoring policy to the *Agent Managed Computers* management group. The monitoring policy creates an AMHealth_HeartbeatWin job on Windows agents and an AMHealth_HeartbeatUNIX job on UNIX agents in repositories running AppManager 8.x or later.

9.6.2 AMHealth_HealthCheckAMCoreComponents Recommended KSG

The following Knowledge Scripts are members of the AMHealth_HealthCheckAMCoreComponents recommended KSG:

- CCComponentsHealth
- QDBComponentsHealth

This KSG creates the AMHealth_QDBComponentsHealth job on agents with the management server or AppManager Repository role. In addition, this KSG creates the AMHealth_CCComponentsHealth job on agents with the Control Center Command Queue Service (CQS), the Control Center repository (NQCCDB), the Control Center Cache Manager, or the Control Center Deployment Service.

10 Apache UNIX Knowledge Scripts

The AppManager category provides the following Knowledge Scripts for monitoring Apache UNIX servers.

From the Knowledge Script view of the Control Center Console, you can access more information about any NetIQ-supported Knowledge Script by selecting it and pressing F1.

Knowledge Script	What It Does
AccessActivity	Monitors requests and the status codes of request errors.
AccessLogEntries	Monitors the number of new entries and content of new entries made to the access logs since last script execution.
Availability	Verifies that the root Apache process is running on an Apache Web Server or IBM HTTP Server.
ConfigFileUpdateCheck	Reports any configuration changes to Apache Web Servers and IBM HTTP Servers.
ConfigTest	Verifies the configuration of an Apache Web Server or IBM HTTP Server.
CoreDumpCheck	Checks for newly created core dump files on an Apache Web Server or IBM HTTP Server and reports the time the last file was created.
CPU	Monitors the percentage of CPU used by Apache processes.
ErrorLogEntries	Monitors the number of new entries and content of new entries made to the error logs since last script execution.
HealthCheck	Verifies Apache processes are running and servers are able to service requests.
InfoModule	Enables the mod_info module on an Apache Web Server or IBM HTTP Server. Most binary distributions disable this module by default.
KillLongRunningRequests	Kills requests that have been running longer than a specified time threshold.
KillProcessesAboveCPU	Kills runaway processes that are using too much CPU.
ModuleEnabled	Reports which Apache modules are enabled, which means they are loaded and active.
ProcessActivity	Monitors the status of HTTPD processes running on Apache Web Servers and IBM HTTP Servers.
Report_ActivitySummary	Generates a report summarizing the requests, requests by virtual hosts, and server utilization on monitored Apache Web Servers and IBM HTTP Servers.

Knowledge Script	What It Does
Report_HealthSummary	Generates a report summarizing the health of monitored Apache Web Servers and IBM HTTP Servers. This report includes information on availability, core files, error log entries, CPU, and virtual memory utilization.
Report_PerformanceSummary	Generates a report summarizing the throughput performance of monitored Apache Web Servers and IBM HTTP Servers.
Requests	Returns statistics on requests and request processing time data
ServerUtilization	Monitors the percentage of busy and idle processes on Apache Web Servers and IBM HTTP Servers.
StartServer	Starts or restarts specified Apache Web Servers or IBM HTTP Servers.
StatusModule	Enables the mod_status module on an Apache Web Server or IBM HTTP Server. Most binary distributions of Apache disable this module by default.
StopServer	Stops specified Apache Web Servers and IBM HTTP Servers.
Throughput	Returns statistics on throughput data.
TopNPageActivity	Lists the most popular Web pages on an Apache Web Server or IBM HTTP Server.
Uptime	Reports the time an Apache Web Server or IBM HTTP Server has been running. Uptime is reset if the Apache root process is killed for any reason.
VirtualMemory	Reports the total memory used by Apache processes, as well as returning this value as a percentage of total available memory.

10.1 AccessActivity

Use this Knowledge Script to monitor access activity on Apache Web Servers and IBM HTTP Servers. This script returns information, such as status codes, about successful and failed requests.

You can use this script to determine which errors clients experience most frequently while accessing a server. This information is critical for maintaining and troubleshooting Web sites. For example, if the script returns multiple instances of status code 404 (file not found), you may have broken links or missing pages on your site.

To use this Knowledge Script, you must have the Apache CustomLog directive configured as `common` or `combined`. For information about how to configure the CustomLog directive, see your Apache documentation.

10.1.1 Resource Objects

Apache Web Server or IBM HTTP Server

10.1.2 Default Schedule

The default interval for this script is **Daily at 2 AM**.

10.1.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Raise event if any threshold exceeded? (y/n)	Set to y to raise events. The default is y.
Event severity when script fails	Set the severity level, from 1 to 40, to indicate the importance of the event. The default is 10, which is the red event indicator.
Event severity when any threshold exceeded	Set the severity level, from 1 to 40, to indicate the importance of the event. The default is 25, which is the blue event indicator.
Filter: regular expression	Specify a filter using a regular expression. This version supports filtering by virtual host only. The default is none.
Collect data for total requests? (y/n)	Set to y to collect data for charts and reports. If set to y, this script returns the total number of requests to the Apache Web Server or IBM HTTP Server. The default is n.
Threshold – Maximum total requests	Specify a threshold value using an integer greater than or equal to -1. If Total Requests exceed the threshold value, an event is raised. Use -1 to ignore this threshold. The default is 0.
Collect data for successes?	Set to y to collect data for charts and reports. If set to y, this script returns the number of successful requests to the Apache Web Server or IBM HTTP Server. The default is n.
Threshold – Maximum successes	Specify a threshold value using an integer greater than or equal to -1. If Successes exceed the threshold value, an event is raised. Use -1 to ignore this threshold. The default is 0.

Description	How to Set It
Collect data for failures? (y/n)	Set to y to collect data for charts and reports. If set to y this script returns the number of failed requests to the Apache Web Server or IBM HTTP Server. The default is n.
Threshold–Maximum failures	Specify a threshold value using an integer greater than or equal to -1. If Failures exceed the threshold value, an event is raised. Use -1 to ignore this threshold. The default is 0.
Collect data for 3XX status codes? (y/n)	Set to y to collect data for charts and reports. If set to y, this script returns the number of 3XX status codes. The default is n.
Threshold – Maximum 3xx status codes	Specify a threshold value using an integer greater than or equal to -1. If the total number of 3XX status codes exceeds the threshold value, an event is raised. Use -1 to ignore this threshold. The default is 0.
Collect data for 4XX status codes? (y/n)	Set to y to collect data for charts and reports. If set to y, this script returns the number of 4XX status codes. The default is n.
Threshold – Maximum 4xx status codes	Specify a threshold value using an integer greater than or equal to -1. If the total number of 4XX status codes exceeds the threshold value, an event is raised. Use -1 to ignore this threshold. The default is 0.
Collect data for 5XX status codes? (y/n)	Set to y to collect data for charts and reports. If set to y, this script returns the number of 5XX status codes. The default is n.
Threshold – Maximum 5xx status codes	Specify a threshold value using an integer greater than or equal to -1. If the total number of 5XX status codes exceeds the threshold value, an event is raised. Use -1 to ignore this threshold. The default is 0.

10.2 AccessLogEntries

Use this Knowledge Script to monitor the number of new entries and the content of new entries made to the access logs since the last execution of this script. As long as the script is running as a regularly scheduled job, each time the script runs, AppManager only reports new entries that have appeared since the last time the script ran.

10.2.1 Resource Objects

Apache Web Server or IBM HTTP Server

10.2.2 Default Schedule

The default interval for this script is **Every 12 hours**.

10.2.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Raise event if new access log entries detected? (y/n)	Set to y to raise events. The default is y.
Event severity when new access log entries detected	Set the severity level, from 1 to 40, to indicate the importance of the event. The default is 25, which is the blue event indicator.
Filter: regular expression	Specify a regular expression value that the new entries, if present, must match before being reported as new entries.
Collect data for access log entries? (y/n)	Set to y to collect data for charts and reports. If set to y, this script returns the number of new entries in the access logs since the last time the script ran. The default is n.
Raise event every time script executes and no new log entries are found? (y/n)?	Set to y to raise an event each time the script executes and no new error log entries are detected. The default is n.

10.2.4 Example of How this Script Is Used

If you want to only report new lines in the access log for 400 errors, you could specify "4[\d][\d]" for the Filter.

10.3 Availability

Use this Knowledge Script to monitor the availability (up/down status) of Apache Web Servers and IBM HTTP Servers by reporting the percentage of available servers. This script verifies that the root Apache process is running.

If the Apache Web Server or IBM HTTP Server is configured to run multiple root processes, the script reports the server as available (up) if any one of the processes is running, or unavailable (down) if none of the processes is running.

10.3.1 Resource Objects

Apache Web Server or IBM HTTP Server

10.3.2 Default Schedule

The default interval for this script is **Every hour**.

10.3.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Raise event if process found not running? (y/n)	Set to y to raise events. The default is y.
Collect data for process status? (y/n)	Set to y to collect data for charts and reports. If set to y, this script returns 100% if the server is available (up), or 0% if the server is unavailable (down). The default is n.
Event severity when process not running	Set the severity level, from 1 to 40, to indicate the importance of the event. The default is 10, which is the red event indicator.

10.4 ConfigFileUpdateCheck

Use this Knowledge Script to monitor changes to the Apache Web Server or IBM HTTP Server configuration files.

10.4.1 Resource Objects

Apache Web Server or IBM HTTP Server

10.4.2 Default Schedule

The default interval for this script is **Every 12 hours**.

10.4.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Raise event if configuration changes detected? (y/n)	Set to y to raise events. The default is y.
Event severity when configuration changes detected	Set the severity level, from 1 to 40, to indicate the importance of the event. The default is 25, which is the blue event indicator.
Raise event every time script executes? (y/n)	Set to y to raise an event at each iteration of the script. The default is n.

10.5 ConfigTest

Use this Knowledge Script to verify the syntax of the configuration file on an Apache Web Server or IBM HTTP Server. Invalid configuration can prevent the server from starting.

This script can be used to pinpoint configuration errors if, for example, the ExtendedStatus directive is on, but the status module is not enabled.

10.5.1 Resource Objects

Apache Web Server or IBM HTTP Server

10.5.2 Default Schedule

The default interval for this script is **Run once**.

10.5.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Raise event if configuration errors detected? (y/n)	Set to y to raise events. The default is y.
Event severity when script fails	Set the severity level, from 1 to 40, to indicate the importance of the event. The default is 10, which is the red event indicator.
Event severity when script succeeds	Set the severity level, from 1 to 40, to indicate the importance of the event. The default is 35, which is the magenta event indicator.

10.6 CoreDumpCheck

Use this Knowledge Script to check if an Apache Web Server or IBM HTTP Server has created a core dump file since the last time this script was run. This script is useful to determine when an Apache Web Server or IBM HTTP Server failed.

This script looks for the core dump file in the directory where you installed Apache unless you specify a location of the core dump file using the CoreDumpDirectory Directive in the `httpd.conf` file.

10.6.1 Resource Objects

Apache Web Server or IBM HTTP Server

10.6.2 Default Schedule

The default interval for this script is **Run once**.

10.6.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Raise event if new core dump file detected? (y/n)	Set to y to raise events. The default is y.
Collect data for presence of core dump file? (y/n)	Set to y to collect data for charts and reports. If set to y, this script returns 100 if there is a core dump file, or 0 if there is no core dump file. The default is n.
Event severity when new core dump file detected	Set the severity level, from 1 to 40, to indicate the importance of the event. The default is 25, which is the blue event indicator.
Event severity when script succeeds	Set the severity level, from 1 to 40, to indicate the importance of the event. The default is 35, which is the magenta event indicator.
Path to gdb	This parameter was required for older versions of the UNIX agent. Version 7.1 and later of the UNIX agent do not require the GNU debugger, so this parameter is no longer required.
Regular expression for name of the core dumped files	Specify the expression that defines the naming convention for the core dump files. Only set this parameter if you use a customized naming convention for core dump files. The default is `^core(\.\d+)?$`.

10.7 CPU

Use this Knowledge Script to monitor CPU activity by Apache processes.

This script is helpful in determining whether an Apache Web Server or IBM HTTP Server needs a more powerful processor.

10.7.1 Resource Objects

Apache Web Server or IBM HTTP Server

10.7.2 Default Schedule

The default interval for this script is **Every hour**.

10.7.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Raise event if CPU utilization exceeds any threshold? (y/n)	Set to y to raise events. The default is y.
Event severity when CPU utilization exceeds threshold	Set the severity level, from 1 to 40, to indicate the importance of the event. The default is 25, which is the blue event indicator.
Collect data for percentage of CPU load? (y/n)	Set to y to collect data for charts and reports. If set to y, this script returns the percent of CPU load attributed to Apache processes. The default is n.
Threshold – Maximum percentage of CPU load	Specify a threshold value using an integer greater than or equal to -1 and less than or equal to 100. If Apache processes exceed this threshold, an event is raised. Use -1 to ignore this threshold. The default is 0.
Collect data for total CPU time? (y/n)	Set to y to collect data for charts and reports. If set to y, this script returns the total CPU time in seconds consumed by Apache processes. The default is n.
Threshold – Maximum total CPU time	Specify a threshold value using an integer greater than or equal to -1. If Apache processes exceed this threshold, an event is raised. Use -1 to ignore this threshold. The default is 0.

10.8 ErrorLogEntries

Use this Knowledge Script to monitor the number of new entries and the content of new entries made to the error logs since the last execution of this script. As long as the script is running as a regularly scheduled job, each time the script runs, AppManager only reports new entries that have appeared since the last time the script ran.

10.8.1 Resource Objects

Apache Web Server or IBM HTTP Server

10.8.2 Default Schedule

The default interval for this script is **Every 12 hours**.

10.8.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Raise event if new error log entries found? (y/n)	Set to y to raise events. The default is y.
Event severity when new error log entries detected	Set the severity level, from 1 to 40, to indicate the importance of the event. The default is 25, which is the red event indicator.
Filter: regular expression	Specify a regular expression value that the new entries, if present, must match before being reported as new entries.
Collect data for error log entries? (y/n)	Set to y to collect data for charts and reports. If set to y, this script returns the number of new error log entries. The default is n.
Raise event every time script executes and no new log entries are found? (y/n)?	Set to y to raise an event each time the script executes and no new error log entries are detected. The default is n.

10.8.4 Example of How this Script is Used

If you want to only report new lines in the error log that are critical, you can specify “crit” for the Filter.

10.9 HealthCheck

Use this Knowledge Script to make sure Apache processes are running and Apache Web Servers and IBM HTTP Servers are able to service requests. This script performs the following checks:

- Verifies all Apache processes (HTTPD processes) are running.
- Verifies the default page for each virtual host is available (status code 200).
- Verifies a list of specified URLs is available (status code 200). This script only checks the target page. This script does not verify pages that are linked from the target page, internal links to other locations in the target page, or pages that appear if the page automatically redirects to another URL when opened.

You can also use the HealthCheck script to:

- Restart servers if the script determines Apache processes are not running.
- Set response time thresholds for virtual hosts and URLs.
- Raise events with user-defined severity levels if Apache services are not running, or a virtual host or URL is not responding.

This Knowledge Script fails if you run the UNIX agent computer as a non-root user.

10.9.1 Resource Objects

Apache Web Server or IBM HTTP Server

10.9.2 Default Schedule

The default interval for this script is **Daily at 2 AM**.

10.9.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Raise events? (y/n)	Set to y to raise events. The default is y.
Collect data for Web server process status? (y/n)	Set to y to collect data for charts and reports. If set to y, this script returns 100 if the HTTPD processes are running, or 0 if those process are not running. The default is n.
Event severity when script fails	Set the severity level, from 1 to 40, to indicate the importance of the event. The default is 10, which is the red event indicator.
Event severity when threshold exceeded	You can set thresholds for virtual host and URL response times. Set the severity level, from 1 to 40, to indicate the importance of the event. The default is 25, which is the blue event indicator.
Restart server if process not running? (y/n)	Set to y to restart the server if Apache processes are not running. The default is y.

Description	How to Set It
Event severity when Apache is not running	Set the severity level, from 1 to 40, to indicate the importance of the event. The default is 10, which is the red event indicator.
Check default page from each virtual host? (y/n)	Set to y to verify availability (status code 200) of the default pages from each virtual host. The default is y.
Threshold – Maximum response time of virtual host	Specify a threshold value using an integer greater than or equal to -1. If virtual host response time (in ms) exceeds the threshold value, an event is raised. Use -1 to ignore this threshold. The default is 0 seconds.
Event severity when virtual host not responding	Set the severity level, from 1 to 40, to indicate the importance of the event. The default is 15 (yellow event indicator).

List of URLs to check (semicolon-separated, no spaces)	Specify a list of URLs to check for availability (status code 200). You must include full URLs, delimited by semicolons. Redirections, internal, and external links are not verified.
	
	When specifying a list of URLs to check, the following characters must be preceded by a backslash (\):
	• & (Ampersand)
	• ? (Question)
	• = (Equal)
	
	For example, an URL that contains:
	
	`login.asp?name=steve{&}password=pass`
	
	Must be specified as:
	
	`login.asp\?name\=steve\{&}password\=pass`
	
	The default is none.

Threshold – Maximum response time for URL	Specify a threshold value using an integer greater than or equal to -1. If URL response time in milliseconds exceeds the threshold value, an event is raised. Use -1 to ignore this threshold. The default is 0 seconds.
Event severity when URL not responding	Set the severity level, from 1 to 40, to indicate the importance of the event. The default is 15, which is the yellow indicator.

10.10 InfoModule

Use this Knowledge Script to enable or disable Apache `mod_info` module. You must enable this module to verify Apache Web Server or IBM HTTP Server configuration at run time.

Running this Knowledge Script restarts the Apache Web Server or IBM HTTP Server.

This Knowledge Script fails if you run the UNIX agent computer as a non-root user.

10.10.1 Resource Objects

Apache Web Server or IBM HTTP Server

10.10.2 Default Schedule

The default interval for this script is **Run once**.

10.10.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Raise event if script succeeds or fails? (y/n)	Set to y to raise events. The default is y.
Enable `mod_info`? (y/n)	Set to y to enable Apache `mod_info` module. The default is y.
Event severity when script succeeds	Set the severity level, from 1 to 40, to indicate the importance of the event. The default is 35, which is the magenta event indicator.
Event severity when script fails	Set the severity level, from 1 to 40, to indicate the importance of the event. The default is 10, which is the red event indicator.
Path to module (may be relative to server Root; semicolon-separated, no spaces)	Specify the directory path of the `mod_info` module. The default is `modules;libexec`.

10.11 KillLongRunningRequests

Use this Knowledge Script to terminate requests that run longer than their allotted threshold. If your web server contains a multi-processing module, such as the worker MPM, each process may contain more than one thread processing a request. If this Knowledge Script terminates a requests on one thread, then the requests on the other threads are also terminated.

This Knowledge Script fails if you run the UNIX agent computer as a non-root user.

10.11.1 Resource Objects

Apache Web Server or IBM HTTP Server

10.11.2 Default Schedule

The default interval for this script is **Every hour**.

10.11.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Raise event if time request has been running exceeds threshold? (y/n)	Set to y to raise events. The default is y.
Collect data for number of killed requests? (y/n)	Set to y to collect data for charts and reports. If set to y, this script returns the number of killed requests. If your server uses the multi-processing module, all requests that belong to the same process are terminated together, so this data does not necessarily represent the number of long running requests. The default is y.
Threshold – Maximum time request can run	Specify a threshold value, in seconds, using an integer greater than or equal to -1. If a single request exceeds the threshold value, the request is killed and an event is raised. Use -1 to ignore this threshold. The default is 900 seconds.
Event severity when processes are killed	Set the severity level, from 1 to 40, to indicate the importance of the event. The default is 20, which is the yellow event indicator.

10.12 KillProcessesAboveCPU

Use this Knowledge Script to kill processes that exceed either the CPU time or CPU percentage threshold. For each process that exceeds a threshold, the event detail message includes the process name, the percentage of CPU used, the CPU time used, and whether the attempt to kill the process was successful or not. If your web server contains the multi-processing module, this Knowledge Script terminates all requests that belong to the same process as the request that runs longer than its allotted threshold.

10.12.1 Resource Objects

Apache Web Server or IBM HTTP Server

10.12.2 Default Schedule

The default interval for this script is **Every hour**.

10.12.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Raise event if any threshold exceeded or process killed? (y/n)	Set to y to raise events. The default is y.
Collect data for number of processes killed? (y/n)	Set to y to collect data for charts and reports. If set to y, this script returns the number of process that were killed. The default is n.
Number of samples to take	Specify the number of times to sample the CPU process list. The default is 10.
Delay between samples	Specify an interval, in seconds, between each sampling of the CPU process list. The default is 1 second.
Threshold – Number of samples exceeding threshold before process killed	This threshold determines how many samples, out of the total number of samples specified above, must exceed the threshold of either CPU percentage or CPU time for a process to be killed. The default is 10 samples.
Threshold – Maximum CPU utilization (percentage)	Specify a threshold value, in percent, using an integer greater than or equal to -1 and less than or equal to 100. If an Apache process exceeds this threshold, an event is raised. Use -1 to ignore this threshold. The default is 95 percent.
Threshold – Maximum CPU utilization (time)	Specify a threshold value, in seconds, using an integer greater than or equal to -1. If an Apache process exceeds this threshold, an event is raised. Use -1 to ignore this threshold. The default is 100 seconds.
Event severity when processes are killed	Set the severity level, from 1 to 40, to indicate the importance of the event. The default is 20, which is the yellow event indicator.

10.13 ModuleEnabled

Use this Knowledge Script to verify whether a specified Apache Web Server or IBM HTTP Server module is enabled, which means the module is loaded and active.

10.13.1 Resource Objects

Apache Web Server or IBM HTTP Server

10.13.2 Default Schedule

The default interval for this script is **Run once**.

10.13.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Raise event if module enabled or disabled? (y/n)	Set to y to raise events. The default is y.
Event severity when module is enabled	Set the severity level, from 1 to 40, to indicate the importance of the event. The default is 35, which is the magenta event indicator.
Event severity when module is disabled	Set the severity level, from 1 to 40, to indicate the importance of the event. The default is 20.
Names of modules to test (semicolon-separated, no spaces)	Specify a list of module names, separated by semicolons, to test for enabled status. The default is `mod_status;mod_info;mod_nqApache223`.

10.14 ProcessActivity

Use this Knowledge Script to monitor the percentage of Apache processes that are serving requests for each virtual host on the server, and for each unique client.

You can use this script to help determine if you are under a denial-of-service attack, for example, if a single client is using an excessive percentage of processes.

10.14.1 Resource Objects

Apache Web Server or IBM HTTP Server

10.14.2 Default Schedule

The default interval for this script is **Every hour**.

10.14.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Raise event if process usage exceeds any threshold? (y/n)	Set to y to raise events. The default is y.
Event severity when script fails	Set the severity level, from 1 to 40, to indicate the importance of the event. The default is 10, which is the red event indicator.
Event severity when process usage exceeds threshold	Set the severity level, from 1 to 40, to indicate the importance of the event. The default is 25, which is the blue event indicator.
Time frame to monitor (times less than supplied value are monitored)	Specify an integer less than or equal to 86400. The units are measured in seconds. The default is 60. HTTPD processes whose most recent request is greater than the specified value are ignored. This allows the script to discount HTTPD processes that have not run within the time window of interest. If this parameter is set to 0, the script will consider all requests during the previous 24 hours.
Collect data per virtual host? (y/n)	Set to y to collect data for charts and reports. If set to y, this script returns the percentage of HTTPD process used by each virtual host. The default is n.
Threshold – Maximum percentage of processes per virtual host	Specify a threshold value using an integer greater than or equal to -1. If a single virtual host exceeds this threshold (percentage of HTTPD processes), an event is raised. Use -1 to ignore this threshold. The default is 0 percentage of HTTPD processes.
Collect data per common client? (y/n)	Set to y to collect data for charts and reports. If set to y, this script returns the percentage of HTTPD processes used by each common client. The default is n.
Threshold – Maximum percentage of processes per common client	Specify a threshold value using an integer greater than or equal to -1. If a common client exceeds this threshold (percentage of HTTPD processes), an event is raised. Use -1 to ignore this threshold. The default is 0 percentage of HTTPD processes.

10.15 Report_ActivitySummary

Use this Report Script to generate a report summarizing the activity of monitored Apache Web Servers and IBM HTTP Servers. The report provides data on the number of total requests and the percentage of processes that are busy and that are on each virtual host.

This Knowledge Script uses data other scripts collect. Before you run this Knowledge Script, you must first run the Throughput, ProcessActivity, and ServerUtilization Knowledge Scripts.

10.15.1 Resource Objects

Report Agent > AM Repositories > *AppManager repository*

10.15.2 Default Schedule

The default schedule is **Run once**.

10.15.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Data source	Use the following parameters to select the data for your report.
Select computer(s)	Click the **Browse [...]** button to start the data wizard. Use the data wizard to select the computers for your report.
Select time range	Click the **Browse [...]** button to open the time browser. Set a specific or sliding time range for data included in your report. The default is Sliding Time: 1 Day; End Now = No
Select peak weekday(s)	Click the **Browse [...]** button to select the days of the week to include in your report. The default is Sunday, Monday, Tuesday, Wednesday, Thursday, Friday, Saturday.
Aggregation by	Select the time period (Hour, Minute, or Day) by which the data in your report is aggregated. The default is Hour.
Aggregation interval	Select the interval between aggregations of the data in your report. This parameter uses the time period specified in the **Aggregation by** parameter to calculate the interval. The default is 1.
Report Component Selection	Use the following parameters to define which data and statistics are displayed in the report.
Include parameter card?	Set to yes to include a card in the report that lists parameter settings for the report script. The default is yes.
Include Total Requests detail table?	Set to yes to include data from the Total Requests detail table in the report. The default is yes.
Include Total Requests chart?	Set to yes to include data from the Total Requests chart in the report. The default is yes.

Description	How to Set It
Threshold on Total Requests chart	Specify an integer to set a threshold for the Total Requests chart. Use -1 to ignore this threshold. The default is 0.
Include Processes per Virtual Host detail table?	Set to yes to include data from the Processes per Virtual Host detail table in the report. The default is yes.
Include Processes per Virtual Host chart?	Set to yes to include data from the Processes per Virtual Host chart in the report. The default is yes.
Threshold on Processes per Virtual Host chart	Specify an integer to set a threshold for the Processes per Virtual Host chart. Use -1 to ignore this threshold. The default is 0.
Include Busy Processes detail table?	Set to yes to include data from the Busy Processes detail table in the report. The default is yes.
Include Busy Processes chart?	Set to yes to include data from the Busy Processes chart in the report. The default is yes.
Threshold on Busy Processes chart	Specify an integer to set a threshold for the Busy Processes chart. Use -1 to ignore this threshold. The default is 0.
Report settings	Use the following parameters to define the graphical presentation of data, the folder where the report is generated, and properties that identify the report.
Customize chart appearance	Click the **Browse [...]** button to open the Chart Settings dialog box. Define the graphic properties of the charts in your report. The default is Ribbon.
Select report location	Click the **Browse [...]** button to open the Publishing Options dialog box. Define the report filename and specify a default folder for this report. The default is ApacheUNIX_ActivitySummary.
Add job ID to output folder name?	Set to yes to append the job ID to the name of the output folder. This is helpful to make the correlation between a specific instance of a Report Script and the corresponding report. The default is no.
Index-Report Title	Click in the Value column, and click the **Browse [...]** button to open the Report Properties dialog box. Set the properties parameters as desired. The default title is ApacheUNIX Activity Summary.
Add time stamp to title	Set to yes to append a time stamp to the title of the report, making each title unique. The time stamp is made up of the date and time the report was generated. Adding a time stamp is useful in order to run consecutive iterations of the same report without overwriting previous output. The default is no.
Event notification	Use the following parameters to raise events associated with generating the report, and to set severity levels for those events.
Raise event for report success?	Set to yes to raise an event when the report is successfully generated. The default is yes.
Severity level for report success	Set the severity level, from 1 to 40, to indicate the importance of the event. The default is 35, which is the magenta level indicator.
Severity level for report with no data	Set the severity level, from 1 to 40, to indicate the importance of the event. The default is 25, which is the blue level indicator.
Severity level for report failure	Set the severity level, from 1 to 40, to indicate the importance of the event. The default is 5, which is the red level indicator.

10.16 Report_HealthSummary

Use this Report Script to generate a report summarizing the health of monitored Apache Web Servers and IBM HTTP Servers. The report provides data on the following:

- Availability
- Core Files
- Error Log Entries
- CPU
- Virtual Memory Utilization

This Knowledge Script uses data other scripts collect. Before you run this Knowledge Script, you must first run the Availability, CoreDumpCheck, ErrorLogEntries, CPU, and VirtualMemory Knowledge Scripts.

10.16.1 Resource Objects

Report Agent > AM Repositories > *AppManager repository*

10.16.2 Default Schedule

The default schedule is **Run once**.

10.16.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Data source	Use the following parameters to select the data for your report.
Select computer(s)	Click the **Browse [...]** button to start the data wizard. Use the data wizard to select the computers for your report.
Select time range	Click the **Browse [...]** button to open the time browser. Set a specific or sliding time range for data included in your report. The default is Sliding Time: 1 Day; End Now = No.
Select peak weekday(s)	Click the **Browse [...]** button to select the days of the week to include in your report. The default is Sunday, Monday, Tuesday, Wednesday, Thursday, Friday, Saturday.
Aggregation by	Select the time period (Hour, Minute, or Day) by which the data in your report is aggregated. The default is Hour.
Aggregation interval	Select the interval between aggregations of the data in your report. This parameter uses the time period specified in the **Aggregation by** parameter to calculate the interval. The default is 1.
Report Component Selection	Use the following parameters to define which data and statistics are displayed in the report.

Description	How to Set It
Include parameter card?	Set to yes to include a card in the report that lists parameter settings for the report script. The default is yes.
Include Availability detail table?	Set to yes to include data from the Availability detail table in the report. The default is yes.
Include Availability chart?	Set to yes to include data from the Availability chart in the report. The default is yes.
Threshold on Availability chart	Specify an integer to set a threshold for the Availability chart. Use -1 to ignore this threshold. The default is 0.
Include Core Files detail table?	Set to yes to include data from the Core Files detail table in the report. The default is yes.
Include Core Files chart?	Set to yes to include data from the Core Files chart in the report. The default is yes.
Threshold on Core Files chart	Specify an integer to set a threshold for the Core Files chart. Use -1 to ignore this threshold. The default is 0.
Include Error Log Entries detail table?	Set to yes to include data from the Error Log Entries detail table in the report. The default is yes.
Include Error Log Entries chart?	Set to yes to include data from the Error Log Entries chart in the report. The default is yes.
Threshold on Error Log Entries chart	Specify an integer to set a threshold for the Error Log Entries chart. Use -1 to ignore this threshold. The default is 0.
Include CPU Utilization detail table?	Set to yes to include data from the CPU Utilization detail table in the report. The default is yes.
Include CPU Utilization chart?	Set to yes to include data from the CPU Utilization chart in the report. The default is yes.
Threshold on CPU Utilization chart	Specify an integer to set a threshold for the CPU Utilization chart. Use -1 to ignore this threshold. The default is 0.
Include Virtual Memory detail table?	Set to yes to include data from the Virtual Memory detail table in the report. The default is yes.
Include Virtual Memory chart?	Set to yes to include data from the Virtual Memory chart in the report. The default is yes.
Threshold on Virtual Memory chart	Specify an integer to set a threshold for the Virtual Memory chart. Use -1 to ignore this threshold. The default is 0.
Report settings	Use the following parameters to define the graphical presentation of data, the folder where the report is generated, and properties that identify the report.
Customize chart appearance	Click the **Browse [...]** button to open the Chart Settings dialog box. Define the graphic properties of the charts in your report. The default is Ribbon.
Select report location	Click the **Browse [...]** button to open the Publishing Options dialog box. Define the report filename and specify a default folder for this report. The default is ApacheUNIX_HealthSummary
Add job ID to output folder name?	Set to yes to append the job ID to the name of the output folder. This is helpful to make the correlation between a specific instance of a Report Script and the corresponding report. The default is no.
Index-Report Title	Click in the Value column, and click the **Browse [...]** button to open the Report Properties dialog box. Set the properties parameters as desired. The default title is ApacheUnix Health Summary.

Description	How to Set It
Add time stamp to title	Set to yes to append a time stamp to the title of the report, making each title unique. The time stamp is made up of the date and time the report was generated. Adding a time stamp is useful in order to run consecutive iterations of the same report without overwriting previous output. The default is no.
Event notification	Use the following parameters to raise events associated with generating the report, and to set severity levels for those events.
Raise event for report success?	Set to yes to raise an event when the report is successfully generated. The default is yes.
Severity level for report success	Set the severity level, from 1 to 40, to indicate the importance of the event. The default is 35, which is the magenta level indicator.
Severity level for report with no data	Set the severity level, from 1 to 40, to indicate the importance of the event. The default is 25, which is the blue level indicator.
Severity level for report failure.	Set the severity level, from 1 to 40, to indicate the importance of the event. The default is 5, which is the red level indicator.

10.17 Report_PerformanceSummary

Use this Report Script to generate a report summarizing the throughput performance of monitored Apache Web Servers and IBM HTTP Servers.

This Knowledge Script uses data other scripts collect. Before you run this Knowledge Script, you must first run the Throughput Knowledge Script.

10.17.1 Resource Objects

Report Agent > AM Repositories > *AppManager repository*

10.17.2 Default Schedule

The default schedule is **Run once**.

10.17.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Data source	Use the following parameters to select the data for your report.
Select computer(s)	Click the **Browse [...]** button to start the data wizard. Use the data wizard to select the computers for your report.
Select time range	Click the **Browse [...]** button to open the time browser. Set a specific or sliding time range for data included in your report.The default is Sliding Time: 1 Day; End Now = No.
Select peak weekday(s)	Click the **Browse [...]** button to select the days of the week to include in your report. The default is Sunday, Monday, Tuesday, Wednesday, Thursday, Friday, Saturday.
Aggregation by	Select the time period (Hour, Minute, or Day) by which the data in your report is aggregated. The default is Hour.
Aggregation interval	Select the interval between aggregations of the data in your report. This parameter uses the time period specified in the **Aggregation by** parameter to calculate the interval. The default is 1.
Report Component Selection	Use the following parameters to define which data and statistics are displayed in the report.
Include parameter help card?	Set to yes to include a card in the report that lists parameter settings for the report script. The default is yes.
Include Throughput (req/s) detail table?	Set to yes to include data from the Throughput (req/s) detail table in the report. The default is yes.
Include Throughput (req/s) chart?	Set to yes to include data from the Throughput (req/s) chart in the report. The default is yes.
Threshold on Throughput (req/s) chart	Specify an integer to set a threshold for the Throughput (req/s) chart. Use -1 to ignore this threshold. The default is 0.

Description	How to Set It
Include Throughput (bytes/s) detail table?	Set to yes to include data from the Throughput (bytes/s) detail table in the report. The default is yes.
Include Throughput (bytes/s) chart?	Set to yes to include data from the Throughput (bytes/s) chart in the report. The default is yes.
Threshold on Throughput (bytes/s) chart	Specify an integer to set a threshold for the Throughput (bytes/s) chart. Use -1 to ignore this threshold. The default is 0.
Report settings	Use the following parameters to define the graphical presentation of data, the folder where the report is generated, and properties that identify the report.
Customize chart appearance	Click the **Browse [...]** button to open the Chart Settings dialog box. Define the graphic properties of the charts in your report. The default is Ribbon.
Select report location	Click the **Browse [...]** button to open the Publishing Options dialog box. Define the report filename and specify a default folder for this report. The default is ApacheUNIX_PerformanceSummary.
Add job ID to output folder name?	Set to yes to append the job ID to the name of the output folder. This is helpful to make the correlation between a specific instance of a Report Script and the corresponding report. The default is no.
Index-Report Title	Click in the Value column, and click the **Browse (...)** button to open the Report Properties dialog box. Set the properties parameters as desired. The default title is ApacheUNIX Performance Summary.
Add time stamp to title	Set to yes to append a time stamp to the title of the report, making each title unique. The time stamp is made up of the date and time the report was generated. Adding a time stamp is useful in order to run consecutive iterations of the same report without overwriting previous output. The default is no.
Event notification	Use the following parameters to raise events associated with generating the report, and to set severity levels for those events.
Raise event for report success?	Set to yes to raise an event when the report is successfully generated. The default is yes.
Severity level for report success	Set the severity level, from 1 to 40, to indicate the importance of the event. The default is 35, which is the magenta level indicator.
Severity level for report with no data	Set the severity level, from 1 to 40, to indicate the importance of the event. The default is 25, which is the blue level indicator.
Severity level for report failure.	Set the severity level, from 1 to 40, to indicate the importance of the event. The default is 5, which is the red level indicator.

10.18 Requests

Use this Knowledge Script to monitor:

- Maximum processing time
- Average processing time
- Average accesses per connection

You can use this script in capacity planning. For example, if processing time for requests is too long, you may want to upgrade the computer to support the level of Web traffic, or limit the number of other applications running on the computer.

You can also use this script to determine whether enough child processes are being spawned to handle the number of requests. If the data returned for average accesses per connection indicates that each child process is handling too many requests, you can alter your configuration of the server.

10.18.1 Resource Objects

Apache Web Server or IBM HTTP Server

10.18.2 Default Schedule

The default interval for this script is **Daily at 2 AM**.

10.18.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Raise event if any threshold exceeded? (y/n)	Set to y to raise events. The default is y.
Event severity when script fails	Set the severity level, from 1 to 40, to indicate the importance of the event. The default is 10, which is the red event indicator.
Event severity when threshold exceeded	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25, which is the blue event indicator.
Collect data for maximum processing time? (y/n)	Set to y to collect data for charts and reports. If set to y, this script returns the maximum request processing time (in ms) for the last interval. The default is n.
Threshold – Maximum processing time	Specify a threshold value using an integer greater than or equal to -1. If the maximum processing time in milliseconds exceeds this threshold, an event is raised. Use -1 to ignore this threshold. The default is 0 milliseconds.
Collect data for average processing time? (y/n)	Set to y to collect data for charts and reports. If set to y, this script returns the average processing time in milliseconds per request during the last interval. The default is n.
Threshold – Maximum average processing time	Specify a threshold value using an integer greater than or equal to -1. If the average processing time in milliseconds exceeds this threshold, an event is raised. Use -1 to ignore this threshold. The default is 0 milliseconds.

Description	How to Set It
Collect data for average accesses per connection? (y/n)	Set to y to collect data for charts and reports. If set to y, this script returns the average number of accesses per connection, which is the average number of requests handled by each child process. The default is n.
Threshold – Maximum average accesses per connection	Specify a threshold value using an integer greater than or equal to -1. If the average accesses per connection exceeds this threshold, an event is raised. Use -1 to ignore this threshold. The default is 0.

10.19 ServerUtilization

Use this Knowledge Script to monitor the utilization statistics for Apache Web Servers and IBM HTTP Servers. This Knowledge Script tracks the percentage of busy and idle processes on specified servers.

You can use this Knowledge Script to track how busy a server is at a given time. For example, if a server is overutilized, you may want to increase the number of HTTPD processes it is running.

10.19.1 Resource Objects

Apache Web Server or IBM HTTP Server

10.19.2 Default Schedule

The default interval for this script is **Every 10 minutes**.

10.19.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Raise event if any threshold exceeded? (y/n)	Set to y to raise events. The default is y.
Event severity when script fails	Set the severity level, from 1 to 40, to indicate the importance of the event. The default is 10, which is the red event indicator.
Event severity when any threshold exceeded	Set the severity level, from 1 to 40, to indicate the importance of the event. The default is 25, which is the blue event indicator.
Collect data for percentage of processes busy? (y/n)	Set to y to collect data for charts and reports. If set to y, this script returns the percentage of busy processes. The default is n.
Threshold – Maximum percentage of processes busy	Specify a threshold value using an integer greater than or equal to -1. If the percentage of busy processes exceeds this threshold, an event is raised. Use -1 to ignore this threshold. The default is 0 percent.
Collect data for number of busy processes? (y/n)	Set to y to collect data for charts and reports. If set to y, this script returns the number of busy processes. The default is n.
Threshold – Maximum number of busy processes	Specify a threshold value using an integer greater than or equal to -1. If the number of busy processes exceeds this threshold, an event is raised. Use -1 to ignore this threshold. The default is 0 busy processes.
Collect data for number of idle processes? (y/n)	Set to y to collect data for charts and reports. If set to y, this script returns the number of idle processes. The default is n.
Threshold – Maximum number of idle processes	Specify a threshold value using an integer greater than or equal to -1. If the number of idle processes exceeds this threshold, an event is raised. Use -1 to ignore this threshold. The default is 0 idle processes.
Collect data for percentage of allowed requests per child? (y/n)	Set to y to collect data for charts and reports. If set to y, this script returns the percentage of allowed requests. The default is n.

Description	How to Set It
Threshold – Maximum percentage allowed requests per child	Specify a threshold value using an integer greater than or equal to -1. If the percentage of allowed requests per child exceeds this threshold, an event is raised. Use -1 to ignore this threshold. The default is 0 percent.
Collect data for percentage of allowed servers? (y/n)	Set to y to collect data for charts and reports. If set to y, this script returns the percentage of allowed servers. The default is n.
Threshold – Maximum percentage of allowed servers	Specify a threshold value using an integer greater than or equal to -1. If the percentage of allowed servers realized exceeds this threshold, an event is raised. Use -1 to ignore this threshold. The default is 0 percent.

10.20 StartServer

Use this Knowledge Script to start or restart Apache Web Servers and IBM HTTP Servers.

You can use this Knowledge Script as a maintenance tool for remote restarting of Apache Web Servers and IBM HTTP Servers. For example, you can use the default schedule to stop and restart all Apache Web Servers each day at 3:00 A.M. to halt runaway processes.

This Knowledge Script fails if you run the UNIX agent computer as a non-root user.

10.20.1 Resource Objects

Apache Web Server or IBM HTTP Server

10.20.2 Default Schedule

The default interval for this script is **Daily at 3 AM**.

10.20.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Raise event if script succeeds or fails? (y/n)	Set to y to raise events. The default is y.
Collect data for job successful or unsuccessful? (y/n)	Set to y to collect data for reports and graphs. If set to y, this script returns 100 if a restart is successful, or 0 if it is unsuccessful. The default is n.
Event severity when script fails	Set the severity level, from 1 to 40, to indicate the importance of the event. The default is 10, which is the red event indicator.
Event severity when script succeeds	Set the severity level, from 1 to 40, to indicate the importance of the event. The default is 35, which is the magenta event indicator.
Method to use when starting Apache server	Specify a method for starting the specified server: • Start: starts the server. • Restart: stops running processes immediately and restarts the server. • Graceful: allows running processes to finish requests, then restarts the server. The default is Graceful.

10.21 StatusModule

Use this Knowledge Script to enable or disable the `mod_status` module on an Apache Web Server or IBM HTTP Server. You must enable this module for some monitoring Knowledge Scripts to return data. Running this Knowledge Script will restart the Apache Web Server or IBM HTTP Server.

This Knowledge Script fails if you run the UNIX agent computer as a non-root user.

10.21.1 Resource Objects

Apache Web Server or IBM HTTP Server

10.21.2 Default Schedule

The default interval for this script is **Run once**.

10.21.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Raise event if script succeeds or fails? (y/n)	Set to y to raise events. The default is y.
Enable `mod_status`? (y/n)	Set to y to enable Apache `mod_status` module. The default is y.
Event severity when enabling or disabling succeeds	Set the severity level, from 1 to 40, to indicate the importance of the event. The default is 35, which is the magenta event indicator.
Event severity when enabling or disabling fails	Set the severity level, from 1 to 40, to indicate the importance of the event. The default is 10, which is the red event indicator.
Path to module (may be relative to server Root; semicolon-separated, no spaces)	Specify the directory path of the `mod_status` module. The default is `modules;libexec`.

10.22 StopServer

Use this Knowledge Script to stop an Apache Web Server or IBM HTTP Server that is currently running.

This Knowledge Script lets you specify whether to kill running processes and stop the server immediately, or allow processes to finish requests before stopping the server.

You can use this Knowledge Script in conjunction with another script as a troubleshooting tool. For example, if the ProcessActivity Knowledge Script determines that a server is experiencing a denial-of-service attack, the StopServer script can be invoked to stop the server immediately.

This Knowledge Script fails if you run the UNIX agent computer as a non-root user.

10.22.1 Resource Objects

Apache Web Server or IBM HTTP Server

10.22.2 Default Schedule

The default interval for this script is **Daily at 3 AM**.

10.22.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Raise event if script succeeds or fails? (y/n)	Set to y to raise events. The default is y.
Collect data for job successful or unsuccessful? (y/n)	Set to y to collect data for charts and reports. If set to y, the script returns 100 if a server is stopped, or 0 if a server is not stopped. The default is n.
Method to use when stopping Apache server	Specify a method for starting the specified servers: • Stop: stops running processes, finalizes dependencies, then closes dependencies. • Graceful-stop: allows running processes to finish requests, then stops the server. This option is not supported on Apache Web Server 2.0. • **Enforced**: stops running processes and dependencies immediately, without properly finalizing dependencies. The default is Stop.
Event severity when script fails	Set the severity level, from 1 to 40, to indicate the importance of the event. The default is 10, which is the red event indicator.
Event severity when script succeeds	Set the severity level, from 1 to 40, to indicate the importance of the event. The default is 35, which is the magenta event indicator.

10.23 Throughput

Use this Knowledge Script to monitor throughput statistics for Apache Web Servers and IBM HTTP Servers. This Knowledge Script collects data on total bytes, total accesses, requests per second, bytes per second, and bytes per request.

You can use this Knowledge Script to monitor how quickly and efficiently requested data is returned to clients by the Apache Web Server or IBM HTTP Server.

10.23.1 Resource Objects

Apache Web Server or IBM HTTP Server

10.23.2 Default Schedule

The default interval for this script is **Every hour**.

10.23.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Raise event if any threshold exceeded? (y/n)	Set to y to raise events. The default is y.
Event severity when script fails	Set the severity level, from 1 to 40, to indicate the importance of the event. The default is 10, which is the red event indicator.
Event severity when threshold exceeded	Set the severity level, from 1 to 40, to indicate the importance of the event. The default is 25, which is the blue event indicator.
Source of throughput data	This parameter was required for older versions of the UNIX agent. Version 7.1 and later of the UNIX agent automatically use the appropriate source of throughput data, so this parameter is no longer required.
Collect data for total bytes? (y/n)	Set to y to collect data for charts and reports. If set to y, this script returns the total number of bytes. The default is n.
Threshold – Maximum total bytes	Specify a threshold value using an integer greater than or equal to -1.If total bytes exceed the threshold value, an event is raised. Use -1 to ignore this threshold. The default is 0 bytes.
Collect data for total accesses? (y/n)	Set to y to collect data for charts and reports. If set to y, this script returns the total number of accesses. The default is n.
Threshold – Maximum total accesses	Specify a threshold value using an integer greater than or equal to -1. If total accesses exceed the threshold value, an event is raised. Use -1 to ignore this threshold. The default is 0 accesses.
Collect data for requests per second? (y/n)	Set to y to collect data for charts and reports. If set to y, this script returns the number of requests per second. The default is n.
Threshold–Maximum requests per second	Specify a threshold value using an integer greater than or equal to -1. If requests per second exceed the threshold value, an event is raised. Use -1 to ignore this threshold. The default is 0 requests.

Description	How to Set It
Collect data for bytes per second? (y/n)	Set to y to collect data for charts and reports. If set to y, this script returns the number of bytes per second. The default is n.
Threshold–Maximum bytes per second	Specify a threshold value using an integer greater than or equal to -1. If bytes per second exceed the threshold value, an event is raised. Use -1 to ignore this threshold. The default is 0 bytes.
Collect data for bytes per request? (y/n)	Set to y to collect data for charts and reports. if set to y, this script returns the number of bytes per request. The default is n.
Threshold–Maximum bytes per request	Specify a threshold value using an integer greater than or equal to -1. If bytes per request exceed the threshold value, an event is raised. Use -1 to ignore this threshold. The default is 0 bytes.

10.24 TopNPageActivity

Use this Knowledge Script to monitor the pages with the most activity on an Apache Web Server or IBM HTTP Server.

To use this Knowledge Script, you must have the Apache CustomLog directive configured as `common` or `combined`. For information about how to configure the CustomLog directive, see your Apache documentation.

10.24.1 Resource Objects

Apache Web Server or IBM HTTP Server

10.24.2 Default Schedule

The default interval for this script is **Every hour**.

10.24.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Raise events? (y/n)	Set to y to raise events. The default is y.
Collect data for number of times each page accessed? (y/n)	Set to y to collect data for charts and reports. If set to y, this script returns the number of times each monitored page was accessed during the interval. The default is n.
Number of pages with highest activity to monitor	Specify the number of most popular Web pages, which are the pages with the most activity, to list. The default is 5.
Filter: virtual hostname or filename of requests	Specify a filter using a regular expression for matching against the virtual host name and filename of requests. If you are using a virtual host, you must specify an access log for the virtual host using the Apache CustomLog directive.

10.25 Uptime

Use this Knowledge Script to monitor the time that an Apache Web Server or IBM HTTP Server has been running.

10.25.1 Resource Objects

Apache Web Server or IBM HTTP Server

10.25.2 Default Schedule

The default interval for this script is **Every hour**.

10.25.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Raise event if server uptime counter resets? (y/n)	Set to y to raise events. The default is y.
Source of uptime data	This parameter was required for older versions of the UNIX agent. Version 7.1 and later of the UNIX agent automatically use the appropriate source of throughput data, so this parameter is no longer required.
Collect data for server uptime? (y/n)	Set to y to collect data for charts and reports. If set to y, this script returns the amount of time in seconds the server has been running since its last start. The default is n.
Event severity when uptime counter resets	Set the severity level, from 1 to 40, to indicate the importance of the event. The default is 30.

10.26 VirtualMemory

Use this Knowledge Script to monitor virtual memory use, in percent and kilobytes, on an Apache Web Server or IBM HTTP Server.

10.26.1 Resource Objects

Apache Web Server or IBM HTTP Server

10.26.2 Default Schedule

The default interval for this script is **Every hour**.

10.26.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Raise event if any threshold exceeded? (y/n)	Set to y to raise events. The default is y.
Event severity when virtual memory utilization exceeds threshold	Set the severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Collect data for percentage of virtual memory used? (y/n)	Set to y to collect data for charts and reports. If set to y, this script returns the percentage of virtual memory used by the Apache Web Server or IBM HTTP Server. The default is n.
Threshold – Maximum virtual memory utilization (%)	Specify a threshold value using an integer greater than or equal to -1and lesser than or equal to 100. If Apache processes exceed the percentage threshold, an event is raised. Use -1 to ignore this threshold. The default is 0 percent.
Collect data for total virtual memory used? (y/n)	Set to y to collect data for charts and reports. If set to y, this script returns the amount of virtual memory in kilobytes used by the Apache Web Server or IBM HTTP Server. The default is n.
Threshold – Maximum virtual memory utilization (KB)	Specify a threshold value using an integer greater than or equal to -1. If Apache processes exceed the KB threshold value, an event is raised. Use -1 to ignore this threshold. The default is 0 KB.

11 ARCserve Knowledge Scripts

AppManager provides the following Knowledge Scripts for monitoring CA CA ARCserve resources. From the Knowledge Script view of Control Center, you can access more information about any NetIQ-supported Knowledge Script by selecting it and clicking **Help**. In the Operator Console, click any Knowledge Script in the Knowledge Script pane and press **F1**.

Knowledge Script	What It Does
	Monitors the size of the CA ARCserve Activity log.
AlertMediaChange	Monitors the number of jobs that are currently waiting for a change of medium before a backup can proceed.
CanceledJobs	Monitors the number of canceled CA ARCserve jobs.
	Deletes all jobs or specified types of jobs from the job queue.
EventLog	Scans the Windows Application event log for entries created by CA ARCserve and returns data about those entries.
FailedJobs	Monitors the number of failed CA ARCserve jobs.
HungJobs	Checks for backup jobs that started but did not finish.
IncompleteJobs	Monitors the number of incomplete CA ARCserve jobs.
LogFiles	Monitors the number of log files CA ARCserve has generated in its Log directory; also deletes old log files.
Report_ActivityLogSize	Generates a report about the size of the ARCserve Activity log.
	Generates a report about the CPU and memory utilization of ARCserver services.
Report_NumberofCanceledJobs	Generates a report about the number of canceled ARCserve jobs.
Report_NumberofFailedJobs	Generates a report about the number of failed ARCserve jobs.
Report_NumberofIncompleteJobs	Generates a report about the number of incomplete ARCserve jobs.
Report_NumberofSuccessfulJobs	Generates a report about the number of successful ARCserve jobs.
RescheduleJobs	Adjusts the scheduled run time of all jobs in the CA ARCserve job queue.
ResourceHigh	Monitors the CPU and memory utilization of CA ARCserve services.
ServiceDown	Monitors CA ARCserve services to see if they are running.

Knowledge Script	What It Does
SetLoggingType	Configures CA ARCserve to write event information to the Windows Application event log.
SuccessfulJobs	Monitors the number of successful CA ARCserve jobs.

11.1 ActivityLogSize

Use this Knowledge Script to monitor the size of the CA ARCserve Activity log file (`CA ARCserve.log`). When the size of the log exceeds the threshold you set, an event is raised.

NOTE: If both ARCserve and ARCserveIT are installed on the same computer, only the ARCserveIT Activity log is monitored.

11.1.1 Resource Objects

CA ARCserve server, CA ARCserveIT server

11.1.2 Default Schedule

The default interval for this script is **Every 10 minutes**.

11.1.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to y to raise events. The default is y.
Collect data?	Set to y to collect data for reports and graphs. When set to y, returns the size of the Activity Log in megabytes (MB). The default is n.
Maximum threshold for log file	Enter the maximum size that the Activity Log file can reach before an event is raised. The default is 1000 MB.
Event severity	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default severity level is 5 (red event indicator).

11.2 AlertMediaChange

Use this Knowledge Script to search the ARCserve log for messages indicating that jobs that are currently waiting for a change of medium before a backup can proceed. If the number of jobs exceeds the threshold you set, an event is raised.

When a backup job pauses to wait for new backup media (such as a tape drive) to become available, it writes a media alert message to the log file (`CA ARCserve.log`). The same job may write multiple media alert entries in the log while it is waiting, and then it may continue when the medium becomes available. You can set the threshold to a value that indicates a job has been waiting for a long time (while issuing multiple alerts), or that many jobs are waiting. Or, if you want this Knowledge Script to raise an event anytime it detects even one media alert entry in the log, set the threshold to 0.

NOTE: If both ARCserve and ARCserveIT are installed on the same computer, only the ARCserveIT Activity log is monitored.

11.2.1 Resource Objects

CA ARCserve server, CA ARCserveIT server

11.2.2 Default Schedule

The default interval for this script is **Every hour**.

11.2.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to y to raise events. The default is y.
Collect data?	Set to y to collect data for reports and graphs. When set to y, returns the number of media alerts found in the log during the current interval. The default is n.
Start with new entries?	This parameter controls what the Knowledge Script does on its first iteration: • If set to y, this script does not scan existing entries on its first iteration, and therefore it does not raise events or collect data on its first iteration. On subsequent iterations, this script only scans new entries written to the log file since the last monitoring interval. • If set to n, this script scans all existing entries on its first iteration and therefore can raise events and collect data on its first interval. On subsequent iterations, this script only scans new entries written to the log file since the last monitoring interval. The default is n.
Maximum threshold for media alerts	Enter the maximum number of media alert messages allowed during any single scan of the CA ARCserve log file before an event is raised. If you specify 0, the script raises an event when it finds any media alerts. The default is 0 alert messages.

Description	How to Set It
Event severity	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default severity level is 5 (red event indicator).

11.3 CanceledJobs

Use this Knowledge Script to check for canceled CA ARCserve jobs and to return data about those jobs.

This script periodically scans the latest CA ARCserve Activity log file (`CA ARCserve.log`) for entries that indicate a job was canceled. If, during any monitoring interval, the number of canceled jobs found in the `CA ARCserve.log` file exceeds the threshold you set, an event is raised.

When an event is raised, the contents of the event detail message depend on whether you are also collecting data. When the Knowledge Script is collecting data, the event detail message reports the number of canceled jobs. The data detail message contains the actual log entries. When the Knowledge Script is not collecting data, the event detail message returns all of the log entries related to canceled jobs.

NOTE: If both ARCserve and ARCserveIT are installed on the same computer, only the ARCserveIT jobs are monitored.

11.3.1 Resource Objects

CA ARCserve server, CA ARCserveIT server

11.3.2 Default Schedule

The default interval for this script is **Every hour**.

11.3.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to y to raise events. The default is y.
Collect data?	Set to y to collect data for reports and graphs. If set to y, returns the number of canceled jobs. The default is n.
Start with new entries?	This parameter controls what the Knowledge Script does on its first iteration: • If set to y, this script does not scan existing entries on its first iteration, and therefore does not raise events or collect data on its first iteration. On subsequent iterations, this script only scans the new entries that are written to the log file since the last monitoring interval. • If set to n, this script scans all existing entries on its first iteration and therefore can raise events and collect data on its first iteration. On subsequent iterations, this script only scans the new entries that are written to the log file since the last monitoring interval. The default is n.
Include • error messages? • warning messages?	Set either of these parameters to y to collect error and warning messages. This script always returns informational messages related to canceled jobs.

Description	How to Set It
Maximum threshold for canceled jobs	Enter the maximum number of canceled jobs allowed during any monitoring interval before an event is raised. The default is 10 canceled jobs.
Event severity	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default severity level is 5 (red event indicator).

11.4 DeleteJobs

Use this Knowledge Script to delete all jobs or specific types of jobs from the CA ARCserve job queue. An event is raised if any jobs are successfully deleted. The event detail message reports the number of jobs actually deleted and also indicates when some jobs could not be deleted.

NOTE: If both ARCserve and ARCserveIT are installed on the same computer, only the ARCserveIT jobs are deleted.

11.4.1 Resource Objects

CA ARCserve server, CA ARCserveIT server

11.4.2 Default Schedule

By default, this script runs only once.

11.4.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event when job is successful?	Set this parameter to y to raise an event when the job succeeds. The default is n. Note This script always raises an event when the job fails.
Event severity level when job is successful	If you set the previous parameter to y, set the event severity level, from 1 to 40, to indicate the job ran successfully. The default severity level is 25 (blue event indicator). Note This script raises an event of severity 5 (red event indicator) when the job fails.
Collect data?	Set to y to collect data for reports and graphs. If set to y, returns the number of jobs successfully deleted. The default is n.
Delete all jobs?	Set this parameter to y to delete all jobs in the CA ARCserve job queue. If set to y, any settings you select for the **Delete jobs of type** parameters are ignored. The default is n.
Delete jobs of type: • Backup • Restore • Copy • Count	If you disabled the **Delete all jobs** parameter, set any of these parameters to y to delete the jobs of that type. The default for each type of job is n.

11.5 EventLog

Use this Knowledge Script to periodically scan the Windows Application event log for entries created by CA ARCserve. (The source label for these entries will be one of the following: `CA ARCserve`, `CA ARCserveIT`, or `CA_LIC`.) If any CA ARCserve entries are found, an event is raised.

When this Knowledge Script starts, it uses the value specified for the **Start with events in past N hours** parameter to determine how to process entries already in the Application log. As it continues to run at the intervals specified on the **Schedule** tab, it scans the Application log for any new entries created since the last time it checked.

This Knowledge Script does not rely on a threshold to generate an event. When this Knowledge Script scans the Application log, it raises an event when it finds entries created by CA ARCserve. The event detail message returns the text of the CA ARCserve log entries found.

CA ARCserve Knowledge Scripts such as SuccessfulJobs and FailedJobs are available to monitor the most common CA ARCserve tasks. The EventLog Knowledge Script provides a flexible, general-purpose tool for monitoring other types of tasks or conditions that CA ARCserve Exec has written to the Application log. To fine-tune event log monitoring:

- Use the **Monitor events of type** parameters to scan only for certain types of events, such as Warning events.
- Use the **Filter the [...] field for** parameters to scan only for specific information, such as events with a specific ID.

NOTE: To use this Knowledge Script successfully, make sure ARCserve is configured to write event information to the Windows Application event log. You can use the SetLoggingType Knowledge Script to configure ARCserve to use the Application log. For more information, see SetLoggingType.

11.5.1 Resource Objects

CA ARCserve server, CA ARCserveIT server

11.5.2 Default Schedule

The default interval for this script is **Every 24 hours**.

11.5.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to y to raise events. The default is y.
Collect data?	Set to y to collect data for reports and graphs. If set to y, returns the number of new event log entries. The default is n.

Description	How to Set It
Start with events in past N hours	Set this parameter to determine which events are included in the search the first time the Knowledge Script is run. Subsequent searches begin where the last search finished. The following entries are valid: • -1 – search all current and previous Application log events during the first monitoring interval. • 0 – search only for events created since the last monitoring interval; previous events are not searched. • *N* – search events logged in the past *N* hours to the Application log. For example, enter 8 to scan the last 8 hours of the Application log for matching entries. The default is 0.
Monitor for events of type: • Error • Warning • Information	Set to y for each type of event you want to monitor. If you disable any of these parameters, that type of entry does not raise an event, is not returned in an event detail message, and is not collected as data if you've enabled the **Collect data** parameter. The default is y.
Filter the [...] field for	To limit the types of log entries that raise events and the type of data that is collected, enter a search string that filters the following fields in the event log: • **Event ID**. Specify a single CA ARCserve event ID or a range of event IDs separated by commas. For example: 1,2,10-15,202. • **Event Description**. Specify a description or keywords in the description. You can specify multiple descriptions separated by commas. The search string can contain criteria used to include entries, exclude entries, or both. Separate the include and exclude criteria with a colon (:). If you are specifying only include criteria, the colon is not necessary.
Maximum number of entries per event message	Set the maximum number of Application log events that can be returned in each event report. For example, if this value is set to 30 and 67 Application log events are found, three event reports are created, two reports containing 30 events and one report containing 7 events. The **Message** column on the **Events** tab in the Operator Console or Control Center Console displays the number of events in each event report, the type of log the events are from, and the event report batch number. The batch number is the sequential number of the event report. Batch numbers start at 1 for each Knowledge Script iteration. The default is 30 entries per event message.
Event severity	Set the event severity level, from 1 to 40, to indicate the importance of the event. You may want to adjust the severity depending on which types of events you are checking for. The default severity level is 8 (red event indicator).

11.6 FailedJobs

Use this Knowledge Script to check for failed CA ARCserve jobs and to return data about those jobs.

This script periodically scans the latest CA ARCserve Activity log file (`CA ARCserve.log`) for entries that indicate a job failed. If the number of failed jobs found in the `CA ARCserve.log` file during any monitoring interval exceeds the threshold you set, an event is raised.

When an event is raised, the contents of the event detail message depend on whether you are also collecting data. When the Knowledge Script is collecting data, the event detail message reports the number of failed jobs. The data detail message contains the actual log entries. When the Knowledge Script is not collecting data, the event detail message returns all of the log entries related to failed jobs.

NOTE: If both ARCserve and ARCserveIT are installed on the same computer, only the ARCserveIT jobs are monitored.

11.6.1 Resource Objects

CA ARCserve server, CA ARCserveIT server

11.6.2 Default Schedule

The default interval for this script is **Every hour**.

11.6.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to y to raise events. The default is y.
Collect data?	Set to y to collect data for reports and graphs. If set to y, returns the number of failed jobs. The default is n.
Start with new entries?	This parameter controls what the Knowledge Script does on its first iteration: • If set to y, this script does not scan existing entries on its first iteration, and therefore does not raise events or collect data on its first iteration. On subsequent iterations, this script only scans the new entries that were written to the log file since the last monitoring interval. • If set to n, this script scans all existing entries on its first iteration and therefore can raise events and collect data on its first iteration. On subsequent iterations, this script only scans the new entries that were written to the log file since the last monitoring interval. The default is n.
Include • error messages? • warning messages?	Set either of these parameters to y to scan error and warning messages. This script always returns informational messages related to canceled jobs.

Description	How to Set It
Maximum threshold for failed jobs	Enter the maximum number of failed jobs allowed during any monitoring interval before an event is raised. The default is 10 failed jobs.
Event severity	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default severity level is 5 (red event indicator).

11.7 HungJobs

Use this Knowledge Script to check for backup jobs that started but did not finish.

Use the **Expected duration of a job** parameter to specify the maximum amount of time, in minutes, that any single job can take to complete. This script periodically scans the latest CA ARCserve Activity log file (`CA ARCserve.log`) and makes a note of the start time of each job it finds. Any job that starts and then does not finish by the time you set as the expected duration considered "hung." If you set a threshold for the number of hung jobs, the script raises an event if the number of hung jobs exceeds this threshold. You can specify a threshold of 0 to receive an event when any job is hung.

NOTE: A job that has finished did not necessarily complete successfully. A job might have failed or have been canceled before the expected duration elapsed. Therefore, HungJobs is not a substitute for the monitoring provided by other ARCserve Knowledge Scripts, such as FailedJobs and CanceledJobs.

If both CA ARCserve and CA ARCserveIT are installed on the same computer, only the CA ARCserveIT jobs are monitored.

11.7.1 Resource Objects

CA ARCserve server, CA ARCserveIT server

11.7.2 Default Schedule

The default interval for this script is **Every hour**.

11.7.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to y to raise events. The default is y.
Collect data?	Set to y to collect data for reports and graphs. If set to y, returns the number of hung jobs. The default is n.
Start with new entries?	This parameter controls what the Knowledge Script does on its first iteration: • If set to y, this script does not scan existing entries on its first iteration, and therefore does not raise events or collect data on its first iteration. On subsequent iterations, this script only scans the new entries that were written to the log file since the last monitoring interval. • If set to n, this script scans all existing entries on its first iteration and therefore can raise events and collect data on its first iteration. On subsequent iterations, this script only scans the new entries that are written to the log file since the last monitoring interval. The default is n.
Jobs to monitor [separated by comma w/o space]	Specify the job ID of the backup job (or jobs) you want to monitor. Separate multiple job IDs with commas; leave this parameter blank to monitor all backup jobs.

Description	How to Set It
Expected duration of a job	Enter the maximum amount of time that any single job can take to complete. A job that does not complete within this expected duration is considered “hung.” The default is 30 minutes.
Maximum threshold for hung jobs	Enter the maximum number of hung jobs allowed before an event is raised. The default is 10 hung jobs.
Maximum number of jobs to monitor	Enter the maximum number of jobs that this Knowledge Script keeps track of at any given moment. By entering as small a number as is practical for your environment, you can fine-tune the amount of system resources that this script consumes. However, if the script reaches the maximum number of jobs, it will not keep track of any new jobs that start. Specify a value that is at least equal to or greater than the threshold you set. The default is 100 jobs.
Event severity	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default severity level is 5 (red event indicator).

11.8 IncompleteJobs

Use this Knowledge Script to check for incomplete CA ARCserve jobs and to return data about those jobs.

This script periodically scans the latest CA ARCserve Activity log file (`CA ARCserve.log`) for entries that indicate a job was incomplete. If, during any interval, the number of incomplete jobs found in the `CA ARCserve.log` file is greater than the threshold you set, an event is raised.

When an event is raised, the contents of the event detail message depend on whether you are also collecting data. When the Knowledge Script is collecting data, the event detail message reports the number of incomplete jobs. The data detail message contains the actual log entries. When the Knowledge Script is not collecting data, the event detail message returns all of the log entries related to incomplete jobs.

NOTE: If both ARCserve and ARCserveIT are installed on the same computer, only the ARCserveIT jobs are monitored.

11.8.1 Resource Objects

CA ARCserve server, CA ARCserveIT server

11.8.2 Default Schedule

The default interval for this script is **Every hour**.

11.8.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to y to raise events. The default is y.
Collect data?	Set to y to collect data for reports and graphs. If set to y, returns the number of incomplete jobs. The default is n.
Start with new entries?	This parameter controls what the Knowledge Script does on its first iteration: • If set to y, this script does not scan existing entries on its first iteration, and therefore does not raise events or collect data on its first iteration. On subsequent iterations, this script only scans the new entries that were written to the log file since the last monitoring interval. • If set to n, this script scans all existing entries on its first iteration and therefore can raise events and collect data on its first iteration. On subsequent intervals, this script only scans the new entries that were written to the log file since the last monitoring interval. The default is n.
Include • error messages? • warning messages?	Set either of these parameters to y to collect error and warning messages. This script always returns informational messages related to canceled jobs.

Description	How to Set It
Maximum threshold for incomplete jobs	Enter the maximum number of incomplete jobs allowed during any monitoring interval before an event is raised. The default is 10 incomplete jobs.
Event severity	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default severity level is 5 (red event indicator).

11.9 LogFiles

Use this Knowledge Script to monitor the number of log files CA ARCserve has generated in its `Log` directory and to delete old log files. If the number of log files found in the CA ARCserve `Log` directory during any monitoring interval exceeds the threshold you set, an event is raised.

NOTE: If both ARCserve and ARCserveIT are installed on the same computer, only the ARCserveIT Activity log files are monitored.

11.9.1 Resource Objects

CA ARCserve server, CA ARCserveIT server

11.9.2 Default Schedule

The default interval for this script is **Every 10 minutes**.

11.9.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to y to raise events. The default is y.
Collect data?	Set to y to collect data for reports and graphs. If set to y, returns the number of log files found. The default is n.
Delete files that are X days old	Enter a number that indicates when to delete old log files. The age of a log file is calculated from its creation date. For example, you might enter 2 days. If this script runs at 3 p.m. on the 25th of the month, it deletes any log files that were created before 3 p.m. on the 23rd of the same month. If you do not want to delete log files, enter 0. The default is 0.
Maximum threshold for log files	Enter the maximum number of log files allowed during any monitoring interval before an event is raised. The default is 1000 log files.
Event severity	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default severity level is 5 (red event indicator).

11.10 Report_ActivityLogSize

Use this ARCserve_Report script to generate a report about the size of the ARCserve Activity log. This report lets you aggregate data by time period (minute, hour, or day) and calculate statistics for each period (for example, the average value per hour).

This report uses data collected by the ActivityLogSize Knowledge Script.

11.10.1 Resource Objects

Report Agent > AM Repositories > *AppManager repository*

11.10.2 Default Schedule

The default schedule is **Run once**.

11.10.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Data source	Use the following parameters to select the data for your report.
Select computer(s)	Click the **Browse [...]** button to start the data wizard. Use the data wizard to select the computers for your report.
Select time range	Click the **Browse [...]** button to open the time browser. Set a specific or sliding time range for data included in your report.
Select peak weekday(s)	Click the **Browse [...]** button to select the days of the week to include in your report.
Data settings	Use the following parameters to define the statistical calculation applied to data, and which of the data is displayed.

Description	How to Set It
Statistics to show	Select a statistical method by which to display data in the report: • **Average**: The average value of data points for the aggregation interval (for example, the average value for 1 Hour) • **Minimum**: The minimum value of data points for the aggregation interval • **Maximum**: The maximum value of data points for the aggregation interval • **Min**/**Avg**/**Max**: The minimum, average, and maximum values of data points for the aggregation interval • **Range**: The range of values in the data stream (maximum - minimum = range) • **StandardDeviation**: The measure of how widely values are dispersed from the mean • **Sum**: The total value of data points for the aggregation interval • **Close**: The last value for the aggregation interval • **Change**: The difference between the first and last values for the aggregation interval (close - open = change) • **Count**: The number of data points for the aggregation interval
Select sorting/display option	Select whether data is sorted, or the method of display: • **No sort**: Data is not sorted • **Sort**: Data is sorted by value (lowest to highest from front to back; highest to lowest from left to right) • **Top %**: Chart only the top N % of selected data (sorted by default) • **Top N**: Chart only the top N of selected data (sorted by default) • **Bottom %**: Chart only the bottom N % of data (sorted by default) • **Bottom N**: Chart only the bottom N of selected data (sorted by default)
Percentage/count for top/bottom	Enter a number for either the percent or count defined in the previous parameter (for example, Top 10%, or Top 10). The default is 25.
Truncate top/bottom?	If set to yes, the data table shows only the top or bottom N or % (for example, only the top 10%). Otherwise, the table shows all data. The default is no.
Show totals on the table?	If set to yes, additional calculations are made for each column of numbers in a table, and the following values are listed at the end of the table: • **Report Average**: An average of all values in a column • **Report Minimum**: The minimum value in a column • **Report Maximum**: The maximum value in a column • **Report Total**: The total of all values in a column The default is no.
Report settings	Use the following parameters to define the graphical presentation of data, the folder where the report is generated, and properties that identify the report.
Include parameter help card?	Set to yes to include a table in the report that lists parameter settings for the report script. The default is yes.

Description	How to Set It
Include table?	Set to yes to include a table of data stream values in the report. The default is yes.
Include chart?	Set to yes to include a chart of data stream values in the report. The default is yes.
Select chart style	Click the **Browse [...]** button to open the Chart Settings dialog box. Define the graphic properties of the charts in your report.
Select output folder	Click the **Browse [...]** button to set parameters for the output folder.
Add job ID to output folder name?	Set to yes to append the job ID to the name of the output folder. This is helpful to make the correlation between a specific instance of a Report Script and the corresponding report. The default is no.
Select properties	Click the **Browse [...]** button to open the Report Properties dialog box. Set the properties parameters as desired.
Add time stamp to title?	Set to yes to append a timestamp to the title of the report, making each title unique. The timestamp is composed of the date and time the report was generated. Adding a timestamp is useful in order to run consecutive iterations of the same report without overwriting previous output. The default is no.
Event notification	Use the following parameters to raise events associated with generating the report, and to set severity levels for those events.
Event for report success?	Set to yes to raise an event when the report is successfully generated. The default is yes.
Severity level for report success	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 35 (magenta level indicator).
Severity level for report with no data	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25 (blue level indicator).
Severity level for report failure.	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 5 (red level indicator).

11.11 Report_CPUandMemoryUsage

Use this ARCserve_Report script to generate a report about the CPU and memory usage of ARCserve services. This report lets you aggregate data by time period (minute, hour, or day) and calculate statistics for each period (for example, the average value per hour).

This report uses data collected by the ResourceHigh Knowledge Script.

11.11.1 Resource Objects

Report Agent > AM Repositories > *AppManager repository*

11.11.2 Default Schedule

The default schedule is **Run once**.

11.11.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Data source	Use the following parameters to select the data for your report.
Select computer(s)	Click the **Browse [...]** button to start the data wizard. Use the data wizard to select the computers for your report.
Select time range	Click the **Browse [...]** button to open the time browser. Set a specific or sliding time range for data included in your report.
Select peak weekday(s)	Click the **Browse [...]** button to select the days of the week to include in your report.
Select the style	Select the style for the report: • **By computer** shows one value for each computer you selected. • **By legend** shows one value for each different legend (the legend is a truncated form of the data stream legend visible in the Operator Console or Control Center Console). • **By computer and legend** shows one value for each unique legend from each computer.
Data settings	Use the following parameters to define the statistical calculation applied to data, and which of the data is displayed.

Description	How to Set It
Statistics to show	Select a statistical method by which to display data in the report: • **Average**: The average value of data points for the aggregation interval (for example, the average value for 1 Hour) • **Minimum**: The minimum value of data points for the aggregation interval • **Maximum**: The maximum value of data points for the aggregation interval • **Min**/**Avg**/**Max**: The minimum, average, and maximum values of data points for the aggregation interval • **Range**: The range of values in the data stream (maximum - minimum = range) • **StandardDeviation**: The measure of how widely values are dispersed from the mean • **Sum**: The total value of data points for the aggregation interval • **Close**: The last value for the aggregation interval • **Change**: The difference between the first and last values for the aggregation interval (close - open = change) • **Count**: The number of data points for the aggregation interval
Select sorting/display option	Select whether data is sorted, or the method of display: • **No sort**: Data is not sorted • **Sort**: Data is sorted by value (lowest to highest from front to back; highest to lowest from left to right) • **Top %**: Chart only the top N % of selected data (sorted by default) • **Top N**: Chart only the top N of selected data (sorted by default) • **Bottom %**: Chart only the bottom N % of data (sorted by default) • **Bottom N**: Chart only the bottom N of selected data (sorted by default)
Percentage/count for top/bottom	Enter a number for either the percent or count defined in the previous parameter (for example, Top 10%, or Top 10). The default is 25.
Truncate top/bottom?	If set to yes, the data table shows only the top or bottom N or % (for example, only the top 10%). Otherwise, the table shows all data. The default is no.
Show totals on the table?	If set to yes, additional calculations are made for each column of numbers in a table, and the following values are listed at the end of the table: • **Report Average**: An average of all values in a column • **Report Minimum**: The minimum value in a column • **Report Maximum**: The maximum value in a column • **Report Total**: The total of all values in a column The default is no.
Report settings	Use the following parameters to define the graphical presentation of data, the folder where the report is generated, and properties that identify the report.
Include parameter help card?	Set to yes to include a table in the report that lists parameter settings for the report script. The default is yes.

Description	How to Set It
Include table?	Set to yes to include a table of data stream values in the report. The default is yes.
Include chart?	Set to yes to include a chart of data stream values in the report. The default is yes.
Select chart style	Click the **Browse [...]** button to open the Chart Settings dialog box. Define the graphic properties of the charts in your report.
Select output folder	Click in the Value column, and click the **Browse [...]** button to set parameters for the output folder.
Add job ID to output folder name?	Set to yes to append the job ID to the name of the output folder. This is helpful to make the correlation between a specific instance of a Report Script and the corresponding report. The default is no.
Select properties	Click in the Value column, and click the **Browse [...]** button to open the Report Properties dialog box. Set the properties parameters as desired.
Add time stamp to title?	Set to yes to append a timestamp to the title of the report, making each title unique. The timestamp is composed of the date and time the report was generated. Adding a timestamp is useful in order to run consecutive iterations of the same report without overwriting previous output. The default is no.
Event notification	Use the following parameters to raise events associated with generating the report, and to set severity levels for those events.
Event for report success?	Set to yes to raise an event when the report is successfully generated. The default is yes.
Severity level for report success	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 35 (magenta level indicator).
Severity level for report with no data	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25 (blue level indicator).
Severity level for report failure.	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 5 (red level indicator).

11.12 Report_NumberofCanceledJobs

Use this ARCserve_Report script to generate a report about the number of canceled ARCserve jobs. This report lets you aggregate data by time period (minute, hour, or day) and calculate statistics for each period (for example, the average value per hour).

This report uses data collected by the CanceledJobs Knowledge Script.

11.12.1 Resource Objects

Report Agent > AM Repositories > *AppManager repository*

11.12.2 Default Schedule

The default schedule is **Run once**.

11.12.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Data source	Use the following parameters to select the data for your report.
Select computer(s)	Click the **Browse [...]** button to start the data wizard. Use the data wizard to select the computers for your report.
Select time range	Click the **Browse [...]** button to open the time browser. Set a specific or sliding time range for data included in your report.
Select peak weekday(s)	Click the **Browse [...]** button to select the days of the week to include in your report.
Data settings	Use the following parameters to define the statistical calculation applied to data, and which of the data is displayed.

Description	How to Set It
Statistics to show	Select a statistical method by which to display data in the report: • **Average**: The average value of data points for the aggregation interval (for example, the average value for 1 Hour) • **Minimum**: The minimum value of data points for the aggregation interval • **Maximum**: The maximum value of data points for the aggreagation interval • **Min**/**Avg**/**Max**: The minimum, average, and maximum values of data points for the aggregation interval • **Range**: The range of values in the data stream (maximum - minimum = range) • **StandardDeviation**: The measure of how widely values are dispersed from the mean • **Sum**: The total value of data points for the aggregation interval • **Close**: The last value for the aggregation interval • **Change**: The difference between the first and last values for the aggregation interval (close - open = change) • **Count**: The number of data points for the aggregation interval
Select sorting/display option	Select whether data is sorted, or the method of display: • **No sort**: Data is not sorted • **Sort**: Data is sorted by value (lowest to highest from front to back; highest to lowest from left to right) • **Top %**: Chart only the top N % of selected data (sorted by default) • **Top N**: Chart only the top N of selected data (sorted by default) • **Bottom %**: Chart only the bottom N % of data (sorted by default) • **Bottom N**: Chart only the bottom N of selected data (sorted by default)
Percentage/count for top/bottom	Enter a number for either the percent or count defined in the previous parameter (for example, Top 10%, or Top 10). The default is 25.
Truncate top/bottom?	If set to yes, the data table shows only the top or bottom N or % (for example, only the top 10%). Otherwise, the table shows all data. The default is no.
Show totals on the table?	If set to yes, additional calculations are made for each column of numbers in a table, and the following values are listed at the end of the table: • **Report Average**: An average of all values in a column • **Report Minimum**: The minimum value in a column • **Report Maximum**: The maximum value in a column • **Report Total**: The total of all values in a column The default is no.
Report settings	Use the following parameters to define the graphical presentation of data, the folder where the report is generated, and properties that identify the report.
Include parameter help card?	Set to yes to include a table in the report that lists parameter settings for the report script. The default is yes.

Description	How to Set It
Include table?	Set to yes to include a table of data stream values in the report. The default is yes.
Include chart?	Set to yes to include a chart of data stream values in the report. The default is yes.
Select chart style	Click the **Browse [...]** button to open the Chart Settings dialog box. Define the graphic properties of the charts in your report.
Select output folder	Click the **Browse [...]** button to set parameters for the output folder.
Add job ID to output folder name?	Set to yes to append the job ID to the name of the output folder. This is helpful to make the correlation between a specific instance of a Report Script and the corresponding report. The default is no.
Select properties	Click the **Browse [...]** button to open the Report Properties dialog box. Set the properties parameters as desired.
Add time stamp to title?	Set to yes to append a timestamp to the title of the report, making each title unique. The timestamp is composed of the date and time the report was generated. Adding a timestamp is useful in order to run consecutive iterations of the same report without overwriting previous output. The default is no.
Event notification	Use the following parameters to raise events associated with generating the report, and to set severity levels for those events.
Event for report success?	Set to yes to raise an event when the report is successfully generated. The default is yes.
Severity level for report success	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 35 (magenta level indicator).
Severity level for report with no data	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25 (blue level indicator).
Severity level for report failure.	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 5 (red level indicator).

11.13 Report_NumberofFailedJobs

Use this ARCserve_Report script to generate a report about the number of failed ARCserve jobs. This report lets you aggregate data by time period (minute, hour, or day) and calculate statistics for each period (for example, the average value per hour).

This report uses data collected by the FailedJobs Knowledge Script.

11.13.1 Resource Objects

Report Agent > AM Repositories > *AppManager repository*

11.13.2 Default Schedule

The default schedule is **Run once**.

11.13.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Data source	Use the following parameters to select the data for your report.
Select computer(s)	Click the **Browse [...]** button to start the data wizard. Use the data wizard to select the computers for your report.
Select time range	Click the **Browse [...]** button to open the time browser. Set a specific or sliding time range for data included in your report.
Select peak weekday(s)	Click the **Browse [...]** button to select the days of the week to include in your report.
Data settings	Use the following parameters to define the statistical calculation applied to data, and which of the data is displayed.

Description	How to Set It
Statistics to show	Select a statistical method by which to display data in the report: • **Average**: The average value of data points for the aggregation interval (for example, the average value for 1 Hour) • **Minimum**: The minimum value of data points for the aggregation interval • **Maximum**: The maximum value of data points for the aggregation interval • **Min**/**Avg**/**Max**: The minimum, average, and maximum values of data points for the aggregation interval • **Range**: The range of values in the data stream (maximum - minimum = range) • **StandardDeviation**: The measure of how widely values are dispersed from the mean • **Sum**: The total value of data points for the aggregation interval • **Close**: The last value for the aggregation interval • **Change**: The difference between the first and last values for the aggregation interval (close - open = change) • **Count**: The number of data points for the aggregation interval
Select sorting/display option	Select whether data is sorted, or the method of display: • **No sort**: Data is not sorted • **Sort**: Data is sorted by value (lowest to highest from front to back; highest to lowest from left to right) • **Top %**: Chart only the top N % of selected data (sorted by default) • **Top N**: Chart only the top N of selected data (sorted by default) • **Bottom %**: Chart only the bottom N % of data (sorted by default) • **Bottom N**: Chart only the bottom N of selected data (sorted by default)
Percentage/count for top/bottom	Enter a number for either the percent or count defined in the previous parameter (for example, Top 10%, or Top 10). The default is 25.
Truncate top/bottom?	If set to yes, the data table shows only the top or bottom N or % (for example, only the top 10%). Otherwise, the table shows all data. The default is no.
Show totals on the table?	If set to yes, additional calculations are made for each column of numbers in a table, and the following values are listed at the end of the table: • **Report Average**: An average of all values in a column • **Report Minimum**: The minimum value in a column • **Report Maximum**: The maximum value in a column • **Report Total**: The total of all values in a column The default is no.
Report settings	Use the following parameters to define the graphical presentation of data, the folder where the report is generated, and properties that identify the report.
Include parameter help card?	Set to yes to include a table in the report that lists parameter settings for the report script. The default is yes.

Description	How to Set It
Include table?	Set to yes to include a table of data stream values in the report. The default is yes.
Include chart?	Set to yes to include a chart of data stream values in the report. The default is yes.
Select chart style	Click the **Browse [...]** button to open the Chart Settings dialog box. Define the graphic properties of the charts in your report.
Select output folder	Click the **Browse [...]** button to set parameters for the output folder.
Add job ID to output folder name?	Set to yes to append the job ID to the name of the output folder. This is helpful to make the correlation between a specific instance of a Report Script and the corresponding report. The default is no.
Select properties	Click the **Browse [...]** button to open the Report Properties dialog box. Set the properties parameters as desired.
Add time stamp to title?	Set to yes to append a timestamp to the title of the report, making each title unique. The timestamp is composed of the date and time the report was generated. Adding a timestamp is useful in order to run consecutive iterations of the same report without overwriting previous output. The default is no.
Event notification	Use the following parameters to raise events associated with generating the report, and to set severity levels for those events.
Event for report success?	Set to yes to raise an event when the report is successfully generated. The default is yes.
Severity level for report success	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 35 (magenta level indicator).
Severity level for report with no data	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25 (blue level indicator).
Severity level for report failure.	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 5 (red level indicator).

11.14 Report_NumberofIncompleteJobs

Use this ARCserve_Report script to generate a report about the number of incomplete ARCserve jobs. This report lets you aggregate data by time period (minute, hour, or day) and calculate statistics for each period (for example, the average value per hour).

This report uses data collected by the IncompleteJobs Knowledge Script.

11.14.1 Resource Objects

Report Agent > AM Repositories > *AppManager repository*

11.14.2 Default Schedule

The default schedule is Run once.

11.14.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Data source	Use the following parameters to select the data for your report.
Select computer(s)	Click the **Browse [...]** button to start the data wizard. Use the data wizard to select the computers for your report.
Select time range	Click the **Browse [...]** button to open the time browser. Set a specific or sliding time range for data included in your report.
Select peak weekday(s)	Click the **Browse [...]** button to select the days of the week to include in your report.
Data settings	Use the following parameters to define the statistical calculation applied to data, and which of the data is displayed.

Description	How to Set It
Statistics to show	Select a statistical method by which to display data in the report: • **Average**: The average value of data points for the aggregation interval (for example, the average value for 1 Hour) • **Minimum**: The minimum value of data points for the aggregation interval • **Maximum**: The maximum value of data points for the aggregation interval • **Min**/**Avg**/**Max**: The minimum, average, and maximum values of data points for the aggregation interval • **Range**: The range of values in the data stream (maximum - minimum = range) • **StandardDeviation**: The measure of how widely values are dispersed from the mean • **Sum**: The total value of data points for the aggregation interval • **Close**: The last value for the aggregation interval • **Change**: The difference between the first and last values for the aggregation interval (close - open = change) • **Count**: The number of data points for the aggregation interval
Select sorting/display option	Select whether data is sorted, or the method of display: • **No sort**: Data is not sorted • **Sort**: Data is sorted by value (lowest to highest from front to back; highest to lowest from left to right) • **Top %**: Chart only the top N % of selected data (sorted by default) • **Top N**: Chart only the top N of selected data (sorted by default) • **Bottom %**: Chart only the bottom N % of data (sorted by default) • **Bottom N**: Chart only the bottom N of selected data (sorted by default)
Percentage/count for top/bottom	Enter a number for either the percent or count defined in the previous parameter (for example, Top 10%, or Top 10). The default is 25.
Truncate top/bottom?	If set to yes, the data table shows only the top or bottom N or % (for example, only the top 10%). Otherwise, the table shows all data. The default is no.
Show totals on the table?	If set to yes, additional calculations are made for each column of numbers in a table, and the following values are listed at the end of the table: • **Report Average**: An average of all values in a column • **Report Minimum**: The minimum value in a column • **Report Maximum**: The maximum value in a column • **Report Total**: The total of all values in a column The default is no.
Report settings	Use the following parameters to define the graphical presentation of data, the folder where the report is generated, and properties that identify the report.
Include parameter help card?	Set to yes to include a table in the report that lists parameter settings for the report script. The default is yes.

Description	How to Set It
Include table?	Set to yes to include a table of data stream values in the report. The default is yes.
Include chart?	Set to yes to include a chart of data stream values in the report. The default is yes.
Select chart style	Click the **Browse [...]** button to open the Chart Settings dialog box. Define the graphic properties of the charts in your report.
Select output folder	Click the **Browse [...]** button to set parameters for the output folder.
Add job ID to output folder name?	Set to yes to append the job ID to the name of the output folder. This is helpful to make the correlation between a specific instance of a Report Script and the corresponding report. The default is no.
Select properties	Click the **Browse [...]** button to open the Report Properties dialog box. Set the properties parameters as desired.
Add time stamp to title?	Set to yes to append a timestamp to the title of the report, making each title unique. The timestamp is composed of the date and time the report was generated. Adding a timestamp is useful in order to run consecutive iterations of the same report without overwriting previous output. The default is no.
Event notification	Use the following parameters to raise events associated with generating the report, and to set severity levels for those events.
Event for report success?	Set to yes to raise an event when the report is successfully generated. The default is yes.
Severity level for report success	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 35 (magenta level indicator).
Severity level for report with no data	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25 (blue level indicator).
Severity level for report failure.	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 5 (red level indicator).

11.15 Report_NumberofSuccessfulJobs

Use this ARCserve_Report script to generate a report about the number of successful ARCserve jobs. This report lets you aggregate data by time period (minute, hour, or day) and calculate statistics for each period (for example, the average value per hour).

This report uses data collected by the SuccessfulJobs Knowledge Script.

11.15.1 Resource Objects

Report Agent > AM Repositories > *AppManager repository*

11.15.2 Default Schedule

The default schedule is **Run once**.

11.15.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Data source	Use the following parameters to select the data for your report.
Select computer(s)	Click the **Browse [...]** button to start the data wizard. Use the data wizard to select the computers for your report.
Select time range	Click the **Browse [...]** button to open the time browser. Set a specific or sliding time range for data included in your report.
Select peak weekday(s)	Click the **Browse [...]** button to select the days of the week to include in your report.
Data settings	Use the following parameters to define the statistical calculation applied to data, and which of the data is displayed.

Description	How to Set It
Statistics to show	Select a statistical method by which to display data in the report: • **Average**: The average value of data points for the aggregation interval (for example, the average value for 1 Hour) • **Minimum**: The minimum value of data points for the aggregation interval • **Maximum**: The maximum value of data points for the aggreagation interval • **Min**/**Avg**/**Max**: The minimum, average, and maximum values of data points for the aggregation interval • **Range**: The range of values in the data stream (maximum - minimum = range) • **StandardDeviation**: The measure of how widely values are dispersed from the mean • **Sum**: The total value of data points for the aggreagation interval • **Close**: The last value for the aggregation interval • **Change**: The difference between the first and last values for the aggregation interval (close - open = change) • **Count**: The number of data points for the aggregation interval
Select sorting/display option	Select whether data is sorted, or the method of display: • **No sort**: Data is not sorted • **Sort**: Data is sorted by value (lowest to highest from front to back; highest to lowest from left to right) • **Top %**: Chart only the top N % of selected data (sorted by default) • **Top N**: Chart only the top N of selected data (sorted by default) • **Bottom %**: Chart only the bottom N % of data (sorted by default) • **Bottom N**: Chart only the bottom N of selected data (sorted by default)
Percentage/count for top/bottom	Enter a number for either the percent or count defined in the previous parameter (for example, Top 10%, or Top 10). The default is 25.
Truncate top/bottom?	If set to yes, the data table shows only the top or bottom N or % (for example, only the top 10%). Otherwise, the table shows all data. The default is no.
Show totals on the table?	If set to yes, additional calculations are made for each column of numbers in a table, and the following values are listed at the end of the table: • **Report Average**: An average of all values in a column • **Report Minimum**: The minimum value in a column • **Report Maximum**: The maximum value in a column • **Report Total**: The total of all values in a column The default is no.
Report settings	Use the following parameters to define the graphical presentation of data, the folder where the report is generated, and properties that identify the report.
Include parameter help card?	Set to yes to include a table in the report that lists parameter settings for the report script. The default is yes.

Description	How to Set It
Include table?	Set to yes to include a table of data stream values in the report. The default is yes.
Include chart?	Set to yes to include a chart of data stream values in the report. The default is yes.
Select chart style	Click the **Browse [...]** button to open the Chart Settings dialog box. Define the graphic properties of the charts in your report.
Select output folder	Click the **Browse [...]** button to set parameters for the output folder.
Add job ID to output folder name?	Set to yes to append the job ID to the name of the output folder. This is helpful to make the correlation between a specific instance of a Report Script and the corresponding report. The default is no.
Select properties	Click the **Browse [...]** button to open the Report Properties dialog box. Set the properties parameters as desired.
Add time stamp to title?	Set to yes to append a timestamp to the title of the report, making each title unique. The timestamp is composed of the date and time the report was generated. Adding a time stamp is useful in order to run consecutive iterations of the same report without overwriting previous output. The default is no.
Event notification	Use the following parameters to raise events associated with generating the report, and to set severity levels for those events.
Event for report success?	Set to yes to raise an event when the report is successfully generated. The default is yes.
Severity level for report success	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 35 (magenta level indicator).
Severity level for report with no data	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25 (blue level indicator).
Severity level for report failure.	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 5 (red level indicator).

11.16 RescheduleJobs

Use this Knowledge Script to adjust the scheduled run time of all jobs in the CA ARCserve job queue. This script works on all jobs in the CA ARCserve job queue. An event is raised if the job fails and, optionally, if the job is successful.

NOTE: If both ARCserve and ARCserveIT are installed on the same computer, only the ARCserveIT jobs are rescheduled.

11.16.1 Resource Objects

CA ARCserve server, CA ARCserveIT server

11.16.2 Default Schedule

By default, this script runs only once.

11.16.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event when job is successful?	Set this parameter to y to raise an event when the job succeeds. The default is n. Note This script always raises an event when the job fails.
Event severity level when job is successful	If you set the previous parameter to y, set the event severity level, from 1 to 40, to indicate that the job ran successfully. The default severity level is 25 (blue event indicator). Note This script raises an event of severity 5 (red event indicator) when the job fails.
Collect data?	Set to y to collect data for reports and graphs. If set to y, returns the number of jobs successfully rescheduled. The default is n.
Adjust all jobs by (+ / -)	Specify the number of minutes to adjust the script's run time: • To reschedule jobs to run earlier, specify a negative number of minutes. Precede the number with a minus sign (-). For example, enter -60. • To reschedule jobs to run later, specify a number of minutes. Do not use a plus sign (+). For example, enter 60. The default is 0 (no adjustment).

11.17 ResourceHigh

Use this Knowledge Script to monitor the CPU and memory utilization of the CA ARCserve services that were found on a managed client during discovery. Monitored CA ARCserve services include:

- Database engine (displayed as **ASDBEngine** in the TreeView)
- Job engine (**ASJobEngine**)
- Tape engine (**ASTapeEngine**)
- Discovery server (**ASDiscoverySvc**)
- Message engine (**ASMsgEngine**)

If you change the number of CA ARCserve services running on a managed client, run the CA ARCserve_Discovery Knowledge Script on that computer again.

You can set two thresholds: one for maximum CPU time and one for maximum memory utilization. If the CPU or memory utilization of any service exceeds the thresholds you set, an event is raised.

11.17.1 Resource Objects

CA ARCserve server, CA ARCserveIT server, individual CA ARCserve services

11.17.2 Default Schedule

The default interval for this script is **Every 10 minutes**.

11.17.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to y to raise events. The default is y.
Collect data?	Set to y to collect data for reports and graphs. If set to y, returns the CPU usage and the memory usage for each service it is monitoring. The default is n.
CPU usage	Enter the maximum amount of CPU resources that you want any single CA ARCserve service to consume before an event is raised. The default is 60%.
Memory usage	Enter the maximum amount of memory that you want any single CA ARCserve service to consume before an event is raised. The default is 6 MB.
Event severity	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default severity level is 8 (red event indicator).

11.18 ServiceDown

Use this Knowledge Script to monitor any CA ARCserve services that were found on a managed client during discovery. All of the following CA ARCserve services may be monitored:

- Database engine (displayed as **ASDBEngine** in the TreeView)
- Job engine (**ASJobEngine**)
- Tape engine (**ASTapeEngine**)
- Discovery server (**ASDiscoverySvc**)
- Message engine (**ASMsgEngine**)

If you change the number of CA ARCserve services running on a managed client, run the CA ARCserve_Discovery Knowledge Script on that computer again.

This Knowledge Script does not rely on a threshold to raise events. If this Knowledge Script finds that any of the services it is monitoring is down, it raises an event. You can configure this Knowledge Script to automatically restart any service that is down.

11.18.1 Resource Objects

CA ARCserve server, CA ARCserveIT server, individual CA ARCserve services

11.18.2 Default Schedule

The default interval for this script is **Every 5 minutes**.

11.18.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Collect data?	Set to y to collect data for reports and graphs. If set to y, returns the value 100 every time it finds a service is up and the value 0 every time it finds a service is down. This provides a way to report on the percentage of system up time in any given period. The default is n.
Auto-start service?	Set to y to automatically restart any service that is down. The default is y.
Severity when auto-start...	You can set the event severity level, from 1 to 40, to indicate the importance when auto-start: • **... fails**. Specify a value that indicates the service is down and AppManager could not restart it. The default is 5 (red event indicator). • **... succeeds**. Specify a value that indicates the service was down and AppManager successfully restarted it. The default is 25 (blue event indicator). • **... is set to n**. Specify a value to indicate the service is down and the restart parameter has been disabled. This default is 18 (yellow event indicator).

11.19 SetLoggingType

Use this Knowledge Script to configure CA ARCserve to write event information to the Windows Application event log. An event can be raised when the job succeeds.

The EventLog Knowledge Script provides a flexible, general-purpose tool for scanning the Windows Application log for entries written by CA ARCserve. However, before running the EventLog Knowledge Script, you must make sure CA ARCserve has been configured to write event information to the Windows Application event log.

You can use the SetLoggingType Knowledge Script to configure CA ARCserve to write event information to the Application log. Or if CA ARCserve is already using the Application log, you can use this Knowledge Script to configure CA ARCserve not to use the Application log.

11.19.1 Resource Object

CA ARCserveIT server

11.19.2 Default Schedule

By default, this script runs only once.

11.19.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event when job is successful?	Set this parameter to y to raise an event when the job succeeds. The default is n. Note This script always raises an event when the job fails.
Event severity level when job is successful	If you set the previous parameter to y, set the event severity level, from 1 to 40, to indicate that the job ran successfully. The default severity level for this parameter is 25 (blue event indicator). Note This script raises an event of severity 5 (red event indicator) when the job fails.
Configure CA ARCserve to use NT event log?	Set to y to configure CA ARCserve to write event information to the Windows Application event log. If CA ARCserve is already configured to use the Application log, set this parameter to n to configure CA ARCserve not to use the Application log. The default is y.

11.20 SuccessfulJobs

Use this Knowledge Script to check for the number of successful CA ARCserve jobs and to return data about those jobs.

This script periodically scans the latest CA ARCserve Activity log file (`CA ARCserve.log`) for entries that indicate a job succeeded. During the first script iteration, this Knowledge Script does not scan existing entries in the log, and therefore does not return any results. As it continues to run at the interval specified on the **Schedule** tab, this script scans the `CA ARCserve.log` file for any new entries created since the last monitoring interval.

If, during any monitoring interval, the number of successful jobs found in the `CA ARCserve.log` file falls below the threshold you specify, an event is raised.

NOTE: If both ARCserve and ARCserveIT are installed on the same computer, only the ARCserveIT jobs are monitored.

11.20.1 Resource Objects

CA ARCserve server, CA ARCserveIT server

11.20.2 Default Schedule

The default interval for this script is **Every hour**.

11.20.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to y to raise events. The default is y.
Collect data?	Set to y to collect data for reports and graphs. If set to y, returns the number of successful jobs found. The default is n.
Minimum threshold for successful jobs	Specify the minimum number of successful jobs required during any interval to prevent an event from being raised. If the number of failed jobs is less than this threshold, an event is raised. The default is 10 successful.
Event severity	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default severity level is 5 (red event indicator).

12 ASYNC Knowledge Scripts

The ASYNC category provides Knowledge Scripts for monitoring Microsoft Windows servers for file changes, event log entries, and SNMP traps as these events occur. The ASYNC Knowledge Scripts run on an asynchronous schedule, which means that they run when a monitored event occurs to provide real-time feedback.

From the Knowledge Script view of Control Center, you can access more information about any NetIQ-supported Knowledge Script by selecting it and clicking **Help**. In the Operator Console, click any Knowledge Script in the Knowledge Script pane and press **F1**.

Knowledge Script	What It Does
FilesChanged	Monitors files for changes as they occur.
NTEventLog	Monitors Windows event logs for new entries matching the include and exclude criteria you define.
NTEventLogRx	Monitors Windows event logs for new entries matching the filter criteria you define using regular expressions.
SNMPTrap	Checks for incoming SNMP traps forwarded from NetIQ Trap Receiver.

12.1 Creating Filters with Regular Expressions

Some Knowledge Scripts enable you to use regular expressions to define include and exclude filters for pattern-matching against the text being evaluated. Depending on the Knowledge Script you are working with, you may be able to use regular expression include and exclude filters when you are setting job properties or you may be able to maintain your search criteria independent of the Knowledge Script parameters in a separate filter file. You may also be able to use regular expression modifiers to further refine your filtering.

For example, if your **include filter** is `replic.*` and you specify the modifier `i` to make the search case-insensitive, the regular expression contains the wildcard (`.`) and repeat (`*`) special characters, indicating you want to find strings that start with `replic` followed by any string of characters. Messages containing either `replication` or `replicated` are captured.

The format is the same for the exclude filter. For example, to find log entries that do not start with the string `success`, the exclude filter might look like this:

```
^success.*
```

If you are only searching for included strings, you can leave the exclude filter blank. If you want to retrieve all messages in the log in a given interval, you can specify `.*` for the include filter and leave the exclude filter blank.

12.1.1 Using Special Characters

The following special characters can be used in regular expressions:

Use This Character	For This Purpose
.	Wildcard for any one character
*	Repeat zero or more occurrences
^	Beginning of the line
\$	End of the line
\	Escape the next meta-character
|	Alternate matches
[ ]	Any character in the class set. You can specify individual characters or ranges.
( )	Grouping characters. For example, you can specify (a|b|c) to indicate a match with a, or b, or c.
+	Quantifier indicating one or more occurrences
?	Quantifier indicating zero or one occurrence
{*n*}	Quantifier indicating exactly *n* occurrence
\w	A word character (alphanumeric plus _)
\s	A white-space character
\d	A digit character

12.1.2 Using Regular Expression Modifiers

In addition to the special characters you can use in creating the regular expression, there are a number of modifiers that can be used to modify how pattern-matching is handled. Valid modifiers include:

Modifier	Description
c	Complements the search list
g	Matches globally as many times as possible
i	Makes the search case-insensitive
m	Treats the string as multiple lines
o	Interpolates variables only once
s	Treats the regular expression string as a single long line
x	Allows for regular expression extensions

For additional information about writing regular expressions, see your Perl documentation or other regular expression resources.

12.2 FilesChanged

Use this Knowledge Script to monitor files for changes to the current size, time stamp, and file attributes. This script raises an event if the size, time stamp, or attribute indicates the file has been modified.

Because this script checks the file properties rather than the file content, you can use this script with almost any file type.

12.2.1 Resource Objects

Windows 2000 Server or later

12.2.2 Default Schedule

The default interval for this script is **Asynchronous**. Regardless of the schedule you select, once you start the Knowledge Script, its job status appears as **Running**.

12.2.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Event?	Set to **y** to raise an event if the size, time stamp, or attribute indicates the file has been modified. The default is y.
Collect data?	Set to **y** to collect data about file modifications. The default is n.

File path	Provide a valid directory path and filename to specify the file (or files) you want to monitor.
	
	To monitor more than one file with a similar name or to monitor the creation and deletion of a file, use pattern-matching characters to specify the filename. Use an asterisk (*) to match all characters and use a question mark (?) to match a single character. For example:
	
	`C:\NetIQ Corporation\Temp\NetIQ Corporation_Debug\Tomc\m?.*`
	
	matches the following files:
	
	`mo.log`
	`mo.log.bkup`
	`ms.log`
	`ms.log.bkup`
	
	To monitor all files in a directory (including new and deleted files), specify a directory path without a filename, for example, `C:\temp`.

Check file size?	Set to **y** to monitor the file's current size. The default is y.
Check file last write time?	Set to **y** to monitor the file's modification time stamp. The default is y.
Check file attribute?	Set to **y** to monitor the file's attributes. The default is y.
Event severity	Set the event severity level, from 1 to 40, to indicate the importance of an event in which file modifications are detected. The default is 8 (red event indicator).

12.3 NTEventLog

Use this Knowledge Script to scan specified Windows logs for entries that match the criteria you specify. You can filter the event log entries by event type and by specifying a combination of include and exclude strings for each event field. This script raises an event when a log entry matches all your filter criteria. All event log entries that match the filtering criteria are returned in the event detail message.

This script requires the Microsoft **EventLog** service to be running on the managed client computer.

When you run this script, only new entries that are written to the event log after you start the job are reported. This script does not re-scan the entire event log each time it runs.

On computers where the Security log is updated frequently, such as domain controller computers, consider using the NetIQ Security Manager product to securely and quickly consolidate Security logs with low impact to the server.

NOTE: To specify filters using regular expressions, use the NTEventLogRx Knowledge Script.

12.3.1 Resource Objects

Windows 2000 Server or later

12.3.2 Default Schedule

The default interval for this script is **Asynchronous**. Regardless of the schedule you select, once you start the Knowledge Script, its job status appears as **Running**.

12.3.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Event?	Set to **y** to raise an event when a log entry matches the criteria you specify. The default is y.
Collect data?	Set to **y** to collect data for charts and reports. When enabled, data collection returns information about log entries that match the criteria you specify. The default is n.
Collect data during Maintenance Mode?	Set to **y** to collect data even if the remote computer is in maintenance mode. The default is n.
Case-sensitive in all filters?	Set to **y** to make all filter statements for this Knowledge Script case-sensitive. The default is n.
Event logs to filter (System, Security, DNS Server, Application)	Specify the names of the Windows event logs you want to filter, separating each log name with a comma. For example, on a Windows 2000 managed client computer, you might specify the following logs: `Security,DNS Server,Application` The default value, `Null`, filters all logs.

Parameter	How to Set It
Filter error events?	Set to **y** to filter error events. The default is y.
Filter warning events?	Set to **y** to filter warning events. The default is y.
Filter information events?	Set to **y** to filter information events. The default is y.
Filter success audit events?	Set to **y** to filter success audit events. The default is y.
Filter failure audit events?	Set to **y** to filter failure audit events. The default is y.
Filter unclassified events?	Some events written to Windows event logs do not have event levels or severities set to event types recognized by Windows Server 2008 and later. This Knowledge Script identifies these entries as unclassified. These entries will not be found by the error, warning, information, success audit, or failure audit filter criteria. Select **y** to monitor log entries that are unclassified. The default is y.
Filter events by source	To filter events generated by a particular source (for example `SQLExecutive`, `SNMP`, or `Service Control Manager`), enter an appropriate filter string. This script looks for matching entries in the event log's **Source** field. Multiple strings can be entered separated by commas. The default value, `Null`, filters log entries from all sources. The filter string can contain criteria used to include entries, exclude entries, or both. Separate the include and exclude criteria with a colon (:). If you specify only include criteria, the colon is not necessary.
Filter events by category	To filter events in a particular category (for example Server or Logon), enter an appropriate filter string. This script looks for matching entries in the event log's **Category** field. Multiple strings can be entered separated by commas. The default value, `Null`, filters log entries from all categories. The filter string can contain criteria used to include entries, exclude entries, or both. Separate the include and exclude criteria with a colon (:). If you specify only include criteria, the colon is not necessary.
Filter events by event ID	To filter events in a particular event ID, enter an appropriate filter string. This script looks for matching entries in the event log's **Event** field. Multiple IDs can be entered separated by commas. For example: `1,2,10,202` The default value, `Null`, filters log entries for all event IDs. The filter string can contain criteria used to include entries, exclude entries, or both. Separate the include and exclude criteria with a colon (:). If you specify only include criteria, the colon is not necessary.
Filter events by user	To filter events associated with a particular user, enter a filter string that includes the user's domain name and user name, separated with a backslash "\". For example, `NetIQ Corporation\Tom Jones`. This script looks for matching entries as they appear in the **User** field of the event log's Event Detail dialog box (To view the Event Details dialog box, double-click a log entry in the Event Viewer). Separate multiple strings with commas (,). The default value, `Null`, filters log entries for all users. The filter string can contain criteria used to include entries, exclude entries, or both. Separate the include and exclude criteria with a colon (:). If you specify only include criteria, the colon is not necessary.

Parameter	How to Set It
Filter events by computer	To filter events generated by a particular computer, enter an appropriate filter string. This script looks for matching entries in the event log's **Computer** field. Multiple strings can be entered separated by commas. The default value, `Null`, filters log entries generated by all computers. The filter string can contain criteria used to include entries, exclude entries, or both. Separate the include and exclude criteria with a colon (:). If you specify only include criteria, the colon is not necessary.
Filter events by event description	To filter events with a particular detail description or containing keywords in the description, enter an appropriate filter string. This script looks for matching entries in the event log's **Description** field. Multiple strings can be entered separated by commas. The default value, `Null`, filters all log entry descriptions. The filter string can contain criteria used to include entries, exclude entries, or both. Separate the include and exclude criteria with a colon (:). If you specify only include criteria, the colon is not necessary.
Severity for error events	Set the event severity level, from 1 to 40, to indicate the importance of an event in which error events are detected. The default is 5 (red event indicator).
Severity for warning events	Set the event severity level, from 1 to 40, to indicate the importance of an event in which warning events are detected. The default is 15 (yellow event indicator).
Severity for information events	Set the event severity level, from 1 to 40, to indicate the importance of an event in which information events are detected. The default is 25 (blue event indicator).
Severity for success audit events	Set the event severity level, from 1 to 40, to indicate the importance of an event in which success audit events are detected. The default is 5 (red event indicator).
Severity for failure audit events	Set the event severity level, from 1 to 40, to indicate the importance of an event in which failure audit events are detected. The default is 5 (red event indicator).
Severity for unclassified events	Set the event severity level, from 1 to 40, to indicate the importance of an event in which unclassified events are detected. The default is 5 (red event indicator).

12.4 NTEventLogRx

Use this Knowledge Script to scan specified Windows logs for entries that match the criteria you specify. You can filter the event log entries by event type and by specifying a combination of include and exclude strings for each event field using regular expressions. This script raises an event when a log entry matches all your filter criteria. All event log entries that match the filtering criteria are returned in the event detail message.

Use the *Filter the [...] field with* parameters to control which fields to filter and the filtering criteria to use to find specific information, such as events associated with a specific user or computer name. With this script, specify the filtering criteria for each field you are interested in using a regular expression, or specify the name of a file that contains all your filtering criteria.

For more information, see "Creating Filters with Regular Expressions" on page 440.

Once you start the Knowledge Script job, any new entries written to the event log that match your criteria are reported. This script does not scan the entire log for any previously-reported events.

This scripts requires the Microsoft **EventLog** service to be running on the managed client computer.

On computers where the Security log is updated frequently, such as domain controller computers, consider using the NetIQ Security Manager product to securely and quickly consolidate Security logs with low impact to the server. For more information, visit the NetIQ Web site at http://www.netiq.com/products/sm/default.asp.

12.4.1 Resource Objects

Windows 2000 Server or later

12.4.2 Default Schedule

The default interval for this script is **Asynchronous**. Regardless of the schedule you select, once you start the Knowledge Script, its job status appears as **Running**.

12.4.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Event?	Set to **y** to raise an event when a log entry matches the criteria you specify. The default is y.
Collect data?	Set to **y** to collect data for charts and reports. When enabled, data collection returns information about log entries that match the criteria you specify. The default is n.
Make filters case-sensitive?	Set to **y** to make all filter statements for this script case-sensitive. The default is n.

Parameter	How to Set It
Event logs to filter for entries	Specify the names of the Windows event logs you want to filter, separating each log name with a pipe character (|). For example, on a Windows 2000 managed client computer, you might specify: `Security|System|Application` When this field is empty (the default value), the script filters all logs.
Filter the [...] field using the regular expression	Use a regular expression to indicate the criteria to look for in each event log field you are interested in: • **Type**. To filter information based on the type of event (such as Error, Warning, Information, Success Audit, Failure Audit), use a regular expression to identify the type of event entries to include. • **Source**. To filter the entries generated by a particular source (such as `SQLExecutive`, `SNMP`, or `Service Control Manager`), use a regular expression to identify the source of event entries to include. • **Category**. To filter information based on a particular category (such as Server or Logon), use a regular expression to identify the category of event entries to include. • **Event ID**. To filter information based on the event ID, use a regular expression to identify the event IDs to include. • **User**. To filter information based on the user name, use a regular expression to identify the user names to include. • **Computer**. To filter information based on the computer name, use a regular expression to identify the computers to include. • **Description**. To filter information based on the event description, use a regular expression to indicate the description to include.
Full path to a file containing filtering criteria	To specify matching expressions in an external file, type the full path to a file containing the filtering criteria you want to match. For example: `C:\TEMP\MyFilters.txt`. **NOTE:** If you specify a filter file, AppManager ignores the *Filter the [...] field with* parameters. However, if AppManager cannot process the filter file, the script raises an event (for example, `fail to process filter file C:\async.xml`) and continues to scan the log files using the filtering criteria you specified in the *Filter the [...] field with* parameters. For more information, see "Using an External Filter File" on page 448.
Severity for error events	Set the event severity level, from 1 to 40, to indicate the importance of an event in which error events are detected. The default is 5 (red event indicator).
Severity for warning events	Set the event severity level, from 1 to 40, to indicate the importance of an event in which warning events are detected. The default is 15 (yellow event indicator).
Severity for information events	Set the event severity level, from 1 to 40, to indicate the importance of an event in which information events are detected. The default is 25 (blue event indicator).
Severity for success audit events	Set the event severity level, from 1 to 40, to indicate the importance of an event in which success audit events are detected. The default is 5 (red event indicator).

Parameter	How to Set It
Severity for failure audit events	Set the event severity level, from 1 to 40, to indicate the importance of an event in which failure audit events are detected. The default is 5 (red event indicator).
Severity for event filtering errors	Set the event severity level, from 1 to 40, to indicate the importance of an event in which filtering errors occurred. The default is 20 (yellow event indicator).

12.4.4 Using an External Filter File

Use this Knowledge Script to specify regular expressions for each event log field as script properties or maintain your search criteria independent of the script parameters in a separate filter file.

In many cases, specifying an external filter file provides greater flexibility and makes modifying your search criteria more straightforward, because you can add almost any number of expressions. You do not need to modify the script properties through the Operator Console or Control Center to pick up your changes.

To use a filter file:

- Identify the strings that you want to find a match for (that is, the entries you want to include in your results).
- Create a text file with one regular expression string per line to locate matching strings. Each line in the file consists of a parameter keyword followed by a colon (:), a tab or blank space, and the regular expression. Or the filter file can be written in XML.
- Ensure the file exists on the target computer.
- Provide the absolute path to the file on the local computer in the *Full path to a file containing filtering criteria* parameter and start the job.

12.4.4.1 Formatting the Filter File

There are two valid formats for the filter file: a simple table format to define the strings to include, and an XML format that allows you to define more complex include and exclude filtering. For both formats, the parameter name keywords are required, but the field values can be left blank if no filtering is needed.

Select a file format appropriate for the complexity of the filtering you need to do.

12.4.4.2 Table Format

The table format provides a simple way to create the filter file. Each filtering section in the file begins with `EventStart` and ends with `EventEnd`. If an entry in the event log matches all the criteria you specified within a filtering section, it is considered a match and an event is raised in AppManager. If you have more than one filtering section, an entry matching either section raises an event.

For example, the following table format file provides two filter sections:

```
EventStart
CaseSensitive:  n
Log:  System
Type:  Error|Warning|Information
Source:  ^SQL*
Category:  *
EVENTID:  1[0-9][0-9][0-9]
User:  Sam|Joe|Chris
Computer:  SFO*
Description:  ($Error.*)|(.*error.*occurred.$)
EventEnd
EventStart
CaseSensitive:  n
Log:  Application
Type:  Error|Warning|Information
Source:  ^SQL*
Category:  *
EVENTID:  1[0-9][0-9][0-9]
User:  Sam|Joe|Chris
Computer:  SFO*
Description:  ($Error.*)|(.*error.*occurred.$)
EventEnd
```

NOTE: If you specify only one filter section, do not include the EventStart and EventEnd lines in the file.

12.4.4.3 XML Format

The XML format is somewhat more sophisticated and more flexible than the table format. The XML format allows you to set both include and exclude filters using the `<Include>` and `<Exclude>` tags and to combine these filter sets to define the search criteria. Each filtering section in the file begins with the `<Events>` tag. An log entry must match all the criteria you specified within a filtering section for it to be considered a match.

For example:

```
<?xml version = "1.0" standalone = "yes"?>
<EventLogConfig Name = "Event Filter" Type = "EVENT_FILTER_CUSTOM" ID = "76">
<Include>
   <Events>
      <Log>Application</Log>
      <Type>INFORMATION|WARNING|ERROR</Type>
      <Source><Net*]></Source>
      <Category>*</Category>
      <EVENTID>2*</EVENTID>
      <User>*</User>
      <Computer>*</Computer>
      <Description><![CDATA[Event.]]></Description>
      <CaseSensitive>y</CaseSensitive>
   </Events>
   <Events>
      <Log>System</Log>
      <Type>Warning</Type>
      <Source>RSVP</Source>
```

```
      <Category>*</Category>
      <EVENTID>*</EVENTID>
      <User>*</User>
      <Computer>SHASTA</Computer>
      <Description>RSVP*</Description>
      <CaseSensitive>y</CaseSensitive>
   </Events>
</Include>
</EventLogConfig>
```

NOTE: If a field contains a regular expression that conflicts with XML syntax or includes special characters, you can use `![CDATA[regular_expression]]` to enclose the expression and prevent parsing problems.

12.5 SNMPTrap

Use this Knowledge Script to check for SNMP traps forwarded from NetIQ Trap Receiver (Trap Receiver). This script raises an event when an SNMP trap is received and when Trap Receiver is unavailable or subsequently becomes available. In addition, this script generates datastreams for Trap Receiver availability. For more information, see "Working with NetIQ Trap Receiver" on page 453.

12.5.1 Prerequisites

- Trap Receiver is not installed automatically when you install the AppManager for Microsoft Windows module. You must start Trap Receiver manually by running the following:

  `\AppManager\bin\NetIQTrapReceiver_Setup.exe`

- This script supports SNMP v1, v2, and v3. If you use SNMP v3, configure your SNMP permissions in AppManager Security Manager. For more information, see "Configuring SNMP Permissions" on page 456.
- Trap Receiver filters SNMP traps based on the criteria you provide in the script parameters: IP address, hostname, or object identifier (OID). This script can translate numerical OIDs to their object descriptor (ODE) counterparts. The translation process requires access to the Management Information Base (MIB) files that reference the OIDs and ODEs. For more information, see "Adding MIBs for Use By Trap Receiver" on page 457.

12.5.2 Resource Objects

Windows 2000 Server or later

12.5.3 Default Schedule

The default interval for this script is **Asynchronous**.

12.5.4 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Job Error Notification	
Event severity when an error occurs	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the SNMPTrap job fails. The default is 15. The default is 15.
Trap Filters	

Parameter	How to Set It
Filter by IP source address or hostname	Provide the IP address or hostname of the SNMP source from which to receive traps. For example: `10.10.10.10` Separate multiple addresses or hostnames with a comma (,). **Notes** • For SNMP v1 and v2, leave this parameter blank (the default) to receive traps from any source IP address or hostname. • For SNMP v3, you must provide at least one IP address or hostname from which to receive traps. Trap Receiver can receive traps only from devices that are registered in `net-snmp` with the appropriate profile information: username, security mode, and passwords.

Filter by object identifier	Provide the object identifier of the trap messages you want to receive. The object identifier is defined by the SNMP source agent.
	You can use OID or ODE notation to specify the object identifier. To filter for more than one object identifier, separate each notation with a comma (,).
	If you leave this parameter blank, the script does not use the object identifier to filter for events.
	If you are using ODE notation, use a case-sensitive descriptor. For example:
	`system.sysUptime.0`
	If you are using OID notation, include the dot (.) at the beginning of the identifier. For example:
	`.1.2.6.1.4.1.1691`
	NOTE: This script filters for an exact match to the OID you provide. If your OID is `.1.2.6.1.4.1.1691`, the script will not match all OIDs that begin with `.1.2.6`. It matches only the OID you specified.

Filter by MIB sub-tree	Provide the part of the MIB tree (sub-tree) about which you want to receive events. For example: `1.3.6.1.4.1.9` Separate multiple sub-trees with a comma (,). If you leave this parameter blank, the script reports events related to the entire MIB tree. You can use this parameter for any trap; however, this parameter uses SNMP v2 terminology.
Filter by generic trap number	Specify a generic trap number to filter trap messages that use the same OID for more than one trap message. You usually do not need to filter for generic trap message numbers if the OID is unique. The generic value of the OID is defined by the SNMP source agent. If you leave this parameter blank, the script does not use a generic value to filter for events.

Parameter	How to Set It
Filter by specific trap number	Specify a specific trap number to filter trap messages that use the same OID for more than one trap message. You usually do not need to filter for specific trap message numbers if the OID is unique. The specific value of the OID is defined by the SNMP source agent. If you leave this parameter blank, the script does not use a specific value to filter for events.
Filter by enterprise	Provide the enterprise from which you want to receive events. The enterprise is defined in MIB 1.3.6.1.4.1.9.87.2. Separate multiple enterprises with a comma (,). If you leave this parameter blank, the script reports events related to all enterprises. You can use this parameter for any trap; however, this parameter uses SNMP v1 terminology.
Event Notification	
Raise event when SNMP trap received?	Select **Yes** to raise an event when an SNMP trap matching your filter criteria is received. The default is Yes.
Event severity when SNMP trap received	Set the event severity level, from 1 to 40, to indicate the importance of an event in which a trap message matches all filter criteria. The default is 15. You can adjust the severity depending on which type of message you are checking for.
Format trap data according to SNMP version	Select the version of SNMP whose formatting should be used for trap event messages. The data provided by each format is the same; only the layout is different.
Raise event for Trap Receiver availability?	Select **Yes** to raise an event when Trap Receiver becomes unavailable and when Trap Receiver becomes available once again. The default is Yes.
Event severity when Trap Receiver is unavailable	Set the severity level, from 1 to 40, to indicate the importance of an event in which Trap Receiver becomes unavailable. The default is 5.
Event severity when Trap Receiver becomes available	Set the severity level, from 1 to 40, to indicate the importance of an event in which Trap Receiver becomes available. The default is 25.
Data Collection	
Collect data for received traps?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns information about received traps based on your search criteria. The default is unselected.
Collect data for Trap Receiver availability?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns “1” if Trap Receiver is available and “0” if Trap Receiver is unavailable. The default is unselected.
Interval for collecting Trap Receiver availability data	Specify the frequency with which the script collects Trap Receiver availability data. The default is every 5 minutes.

12.5.5 Working with NetIQ Trap Receiver

In general, a trap receiver is an application that receives traps from SNMP agents. Trap Receiver receives and filters SNMP traps, and then forwards the traps to AppManager. Trap Receiver runs as a service,

`NetIQTrapReceiver.exe`, and may compete for port usage with any other trap receiver installed on the same computer.

12.5.5.1 What is NetIQ Trap Receiver?

At its most basic, a trap receiver is an application that receives traps from SNMP agents. Trap Receiver receives, filters, and forwards SNMP traps to AppManager. When you use Trap Receiver with the AppManager for Microsoft Windows module, the SNMPTrap Knowledge Script raises events when SNMP traps are received.

12.5.5.2 What is an SNMP Trap?

Simple Network Management Protocol (SNMP) is a protocol-based system used to manage devices on TCP/IP-based networks. From devices on which an SNMP agent resides, such as routers and switches, SNMP sends unsolicited notifications, called traps, to network administrators when thresholds for certain conditions are exceeded. These conditions are defined by the vendor in a device's Management Information Base (MIB). The network administrator sets the thresholds.

Traps are composed of Protocol Data Units (PDUs). Each PDU contains the following information, organized in various ways depending on the version of SNMP in use:

- SNMP version number
- Community name of the SNMP agent
- PDU type
- Enterprise OID (object identifier), a unique number that identifies an enterprise and its system objects in the MIB
- IP address of the SNMP agent
- Generic trap type: Cold start, Warm start, Link down, Link up, Authentication failure, Egp Neighbor Loss, and Enterprise
- Specific trap type. When the Generic trap type is set to "Enterprise," a specific trap type is included in the PDU. A specific trap is one that is unique or specific to an enterprise.
- Time the event occurred
- Varbind (variable binding), a sequence of two fields that contain the OID and a value

12.5.5.3 Understanding Trap Receiver Architecture

Trap Receiver operates on a Client-Server architecture: the *Server*—the stand-alone Trap Receiver application—receives, filters, and forwards SNMP traps to the *Client*—an application that receives traps, such as AppManager. The Server may receive traps from standard UDP port 162 or from any other configured port. The Client and the Server can reside on the same computer or on separate (proxy) computers.

Communication between Client and Server is implemented as XML messages over a TCP connection. Only one Server is allowed per computer, however, several Clients are allowed per computer. Clients that are registered to the same Server share the same TCP connection. The Server TCP port should be known to all potential Clients.

12.5.5.4 Understanding the Trap Receiver Configuration File

The configuration file for Trap Receiver, `NetIQTrapReceiver.conf`, identifies the UDP and TCP ports used by Trap Receiver: the UDP port is used for receiving traps; the TCP port is used for communicating with the Client, such as AppManager or another supported NetIQ application. The configuration file also identifies the level of logging you want to use and whether port forwarding is enabled.

By default, the configuration file is installed in `[`*`installation directory`*`]\config`, and has the following format:

```
############################################################
#
# NetIQTrapReceiver.conf
#
# A configuration file for NetIQ Trap Receiver
#
############################################################
#########################
# TCP port
# Syntax: tcp_port [port]
# E.g. : tcp_port 2735
#########################
tcp_port 2735
#########################
# UDP port
# Syntax: udp_port [port]
# E.g. : udp_port 162
#########################
udp_port 162
#########################
# Forwarding
# Syntax: forward [address]:[port] [v1]
# E.g. : forward 127.0.0.1:1000 v1
#########################
#########################
# Log level
# Syntax: log_level error|warning|info|debug|xml
# E.g. : log_level info
#########################
log_level debug
```

If the configuration file cannot be found, cannot be parsed, or does not contain one of the required values, Trap Receiver is initialized with the default configuration as shown above.

When changing values in the configuration file, take into account the following:

- If you change the TCP port number, stop all asynchronous Knowledge Script jobs associated with the modules that support Trap Receiver. Run the Discovery_NT Knowledge Script on all monitored devices to enable the devices to recognize the new TCP port number.
- If you change the UDP port number, also change the UDP port number configured on the devices that send traps to Trap Receiver.
- If another service uses port 2735 or port 162, Trap Receiver *will not start*. The Trap Receiver log file will contain different levels of messages, based on the log_level you choose. Either change the port numbers in the configuration file, stop the service that is using the default Trap Receiver port numbers, or forward the traps coming in to UDP port 162.

- To forward incoming traps to another trap receiver, such as Microsoft SNMP Trap Service, set the Forwarding values as follows: `forward [IP address of other trap receiver]:[port number of other trap receiver] [SNMP version]`. For example: `forward 10.40.40.25:167 v1`. By default, incoming traps are not forwarded. For more information, see "Coexisting with Microsoft SNMP Trap Service" on page 456.
- Restart Trap Receiver after any change to the configuration file. From Control Panel, double-click **Administrative Tools** and then double-click **Services**. Right-click **NetIQ Trap Receiver** and select **Restart**.

12.5.5.5 Coexisting with Microsoft SNMP Trap Service

Two trap receivers cannot be in use on the same computer while using the same standard UDP port (162). If NetIQ Trap Receiver and another trap receiver such as Microsoft SNMP Trap Service are installed on the same computer and both are receiving traps, then configure Trap Receiver to use the standard UDP port and to forward incoming traps (UDP forwarding) to the other trap receiver. For more information, see "Understanding the Trap Receiver Configuration File" on page 454.

Then, configure the other trap receiver to use a different, non-standard, UDP port that is not in use by another application. The following are instructions for configuring Microsoft SNMP Trap Service.

To configure Microsoft SNMP Trap Service to use another port:

1. Navigate to `\system32\drivers\etc`.
2. Open the **services** file.
3. In the row for `snmptrap`, change the value for **udp** from 162 to another port number that is not in use by any other application. Use the same port number you set as the forwarding port in the Trap Receiver configuration file. For more information, see "Understanding the Trap Receiver Configuration File" on page 454.
4. Save and close the **services** file.
5. Restart Windows SNMP Trap Service. In Control Panel, double-click **Administrative Tools** and then double-click **Services**. Right-click **SNMP Trap Service** and select **Restart**.

TIP: To see which ports are in use, run `netstat.exe` from a command prompt. Then select an available port as the port for the other trap receiver service.

12.5.6 Configuring SNMP Permissions

For each device you want to monitor for SNMP v3 traps, configure Simple Network Management Protocol (SNMP) information in AppManager Security Manager *before* you run the SNMPTrap Knowledge Script. You do not need to configure permissions for SNMP v1 or v2.

By configuring SNMP information, you provide AppManager the permission it needs to access the Management Information Bases (MIBs) on SNMP-enabled devices.

The AppManager for Microsoft Windows module supports the following modes for SNMP v3:

- No authentication; no privacy
- Authentication; no privacy
- Authentication and privacy

In addition, the module supports the following protocols for SNMP v3:

- MD5 (Message-Digest algorithm 5, an authentication protocol)
- SHA (Secure Hash Algorithm, an authentication protocol)
- DES (Data Encryption Standard, encryption protocol)

Your SNMP v3 implementation may support one or more combinations of mode and protocol. That combination dictates the type of information you configure in AppManager Security Manager: user name (or entity), context name, protocol name, and protocol passwords.

Configure SNMP information for each device you want to monitor. On the Custom tab in Security Manager, complete the following fields:

Field	Description
Label	`SNMPTrap`
Sub-label	Indicate whether the community string information will be used for a single device or for all devices: • *For a single device*, type the <*`device name`*>. • *For all devices*, type `default`.
Value 1	SNMP user name, or entity, configured for the device. All SNMP v3 modes require an entry in the **Value 1** field.
Value 2	Name of the context associated with the user name or entity you entered in the **Value 1** field. A context is a collection of SNMP information that is accessible by an entity. If possible, enter a context that provides access to all MIBS for a device. *If the device does not support context*, type an asterisk (`*`). All SNMP v3 modes require an entry in the **Value 2** field.
Value 3	Combination of protocol and password appropriate for the SNMP v3 mode you have implemented. • For *no authentication/no privacy mode*, leave the **Value 3** field blank. • For *authentication/no privacy mode*, type `md5` or `sha` and the password for the protocol, separating each entry with a comma. For example, type `md5,abcdef` • For *authentication/privacy mode*, type `md5` or `sha` and the associated password, and then type des and the associated password, separating each entry with a comma. For example, type `sha,hijklm,des,nopqrs`

12.5.7 Adding MIBs for Use By Trap Receiver

The SNMPTrap Knowledge Script can translate numerical OIDs to their ODE counterparts. The translation process requires access to the Management Information Base (MIB) files that reference the OIDs you specified as filters in the script parameters.

You must copy the necessary MIB files to the default MIBs directory on the computer on which NetIQ Trap Receiver is installed. After installing the MIBs, reload the MIBs directory so the new MIBs can be compiled for use by Trap Receiver.

To add MIBs to the MIB directory and reload the directory:

1. On the computer on which Trap Receiver is installed, copy all necessary MIB files to the default directory: `\Program Files\NetIQ\AppManager\bin\MIBs`. Ensure you copy MIB files for all your modules, not only the MIB files for the module with the trap definition.

2. On that same computer, restart the AppManager agent services: `NetIQmc` (NetIQ AppManager Client Resource Monitor) and `NetIQccm` (NetIQ AppManager Client Communication Manager). Restarting the services allows Trap Receiver to load the MIB files.

13 AvayaCM Knowledge Scripts

AppManager provides the following Knowledge Scripts for monitoring Avaya Communication Manager servers and resources.

From the Knowledge Script view of Control Center, you can access more information about any NetIQ-supported Knowledge Script by selecting it and clicking **Help**. In the Operator Console, click any Knowledge Script in the Knowledge Script pane and press **F1**.

Knowledge Script	What It Does
AddMIB	Adds management information bases for monitoring by the SNMPTrap Knowledge Script.
AddPhone	Adds Avaya IP phones as objects in the TreeView pane.
Announcements	Monitors announcements for queued calls, dropped calls, and peak port usage.
AttendantCalls	Monitors the switch processing element (SPE) for answered calls, abandoned calls, calls on hold, queued calls, active time, and average answer time.
CallActivity	Monitors call activity on selected Communication Managers.
CallFailures	Monitors calls for abnormal causes of termination.
CallQuality	Monitors calls for quality metrics such as jitter, latency, packet loss, MOS (Mean Opinion Score), and R-Value.
CallQuery	Queries call detail records retrieved from Communication Manager and stored in the Avaya CM supplemental database.
CPU_Usage	Monitors a Communication Manager server for system management CPU usage, operating system CPU usage, call processing CPU usage, and available CPU.
ESS_Status	Monitors the registration status of an Enterprise Survivable Server (ESS).
H248GatewayStatus	Monitors H.248 media gateways for alarms and unavailable H.248 links.
HuntGroupUsage	Monitors hunt groups for answered calls, queued calls, abandoned calls, and average call wait time.
LSP_Status	Monitors the registration status of Local Survivable Processors (LSP).
PhoneConnectivity	Monitors disconnected registered phones for a Communication Manager and retains a history of the monitored phones in the Avaya CM supplemental database.
PhoneDeregistrations	Monitors phone deregistrations for a Communication Manager and retains a history of the monitored phones in the Avaya CM supplemental database.

Knowledge Script	What It Does
PhoneInventory	Creates an inventory of the phones configured in a Communication Manager cluster.
PhoneQuality	Collects real-time voice quality statistics for active calls on Avaya IP phones.
RegisteredResources	Monitors changes in the number of resources registered on a Communication Manager server.
RemovePhone	Removes Avaya IP phone objects from the TreeView pane.
RetrieveConfigData	Retrieves Communication Manager configuration data about stations and gateways and stores it in the Avaya CM supplemental database.
SecurityViolations	Monitors security violations for barrier codes, monitors calls that generated authorization code violations, and monitors calls that generated station security violations.
SetupSupplementalDB	Creates an Avaya CM supplemental database in which to store call detail records, disconnected phone information, and deregistered phone information.
SNMPTrap	Checks for incoming SNMP traps forwarded from NetIQ SNMP Trap Receiver.
SystemUptime	Monitors the number of hours a Communication Manager has been operational since its last reboot.
TrunkGroupUsage	Monitors trunk groups for busy time, calls queued and not queued, and out-of-service trunks.
Recommended Knowledge Script Group	Runs all recommended Knowledge Scripts at one time.

13.1 AddMIB

Use this Knowledge Script to add MIB (management information base) files to the MIB tree that is monitored by the SNMPTrap Knowledge Script. The MIB files should be `ASN.1` text files with `.txt` or `.my` file extensions. The MIB files should not be compiled MIB files.

With this script you can copy a MIB file from an arbitrary directory to the MIB tree located in the <*AppManager directory*>`\bin\MIBs` directory. And, by using the *Reload MIB tree?* parameter, you can reload all MIBs in the tree without restarting the AppManager agent. A restart of the AppManager agent automatically reloads the MIB tree.

Scenarios for using this script include the following examples:

In This Scenario	Set These Parameters
You want to add a MIB file to the MIB tree, but do not want the addition to take effect until after the next restart of the AppManager agent.	*Full path to MIB files* and *List of MIB files*: Provide location and name of MIB file you want to add. *Reload MIB tree?*: Set to **No** (unselected).
You manually copied a MIB file to the MIB directory and want to reload all MIBs in the directory.	*Full path to MIB files* and *List of MIB files*: Leave blank. *Reload MIB tree?*: Select **Yes**. *MIB reload timeout*: Set new timeout value or accept default of 10 seconds.
To fix compiler errors, you edited some MIBs in the MIB directory. Now you want to reload the MIBs to ensure the errors have been fixed.	*Full path to MIB files* and *List of MIB files*: Leave blank. *Reload MIB tree?*: Select **Yes**. *MIB reload timeout*: Set new timeout value or accept default of 10 seconds.

13.1.1 Resource Object

AvayaCM Trap Receiver object

13.1.2 Default Schedule

By default, this script runs once.

13.1.3 Setting Parameter Values

Set the following parameters as needed.

Parameter	How to Set It
Full path to MIB files	Specify the full path to the folder that contains the MIB files you want to install. The AppManager agent on the proxy agent computer must have network access to the location you specify.

Parameter	How to Set It
List of MIB files	Provide a comma-separated list of the MIB files you want to install. The MIB files should be `ASN.1` text files with `.txt` or `.my` file extensions. The MIB files should not be compiled MIB files. The MIB files you specify must be located in the folder you identified in the *Full path to MIB files* parameter.
Reload MIB tree?	Select **Yes** to update the MIB tree.
MIB reload timeout	Specify the length of time AppManager should attempt to update the MIB tree before timing out and raising a failure event. The default is 10 seconds.
Event Notification	
Raise event if installation and reloading of MIB tree succeeds?	Select **Yes** to raise an event if installation of the MIB files and reloading of the MIB tree succeeds. The default is Yes. **NOTE:** Reloading of the MIB tree can be successful even if no new MIB files are installed. Reloading of the MIB tree can proceed even if you provide no MIB files in the *List of MIB files* or *Full path to list of MIB files* parameter.
Event severity when installation and reloading of MIB tree succeeds	Set the severity level, from 1 to 40, to indicate the importance of an event in which the installation of MIB files and the reloading of the MIB tree succeeds. The default is 25.
Raise event if reload MIB parser warnings received?	Select **Yes** to raise an event if warning messages are received during the reload process. The default is Yes. Warning scenarios include: • MIBs are installed successfully but the *Reload MIB tree?* parameter is not set to Yes. • Not all specified MIB files were loaded to the MIB tree.
Event severity when reload MIB parser warnings received	Set the severity level, from 1 to 40, to indicate the importance of an event in which warning messages are received during the reload process. The default is 15.
Raise event if installation and reloading of MIB tree fails?	Select **Yes** to raise an event if AppManager fails to install or reload the specified MIB files. The default is Yes. Failure scenarios include: • MIB reload timeout period expired. • Not all specified MIB files were installed.
Event severity when installation and reloading of MIB tree fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the installation or reloading of the MIB tree fails. The default is 10.
Raise event with the list of currently installed MIBs?	Select **Yes** to raise an informational event that provides a list of all MIBs installed in the MIB tree. The default is Yes.
Event severity for the list of currently installed MIBs	Set the severity level, from 1 to 40, to indicate the importance of an event that provides a list of all MIBs installed in the MIB tree. The default is 25.

13.2 AddPhone

Use this Knowledge Script to add Avaya IP phones as objects to be monitored. You must add a phone before you can monitor it with the PhoneQuality script. This script raises an event when phones are added or if phones cannot be added.

When polling a phone to get device information, AppManager has a 20-second timeout period for each phone that it is attempting to contact. If you are adding many phones at one time, this Knowledge Script job may take quite a while if phones cannot be contacted.

13.2.1 Resource Object

AvayaCM Station folder

13.2.2 Default Schedule

By default, this script runs once.

13.2.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Job Failure Notification	
Event severity when job fails	Set the event severity level, from 1 to 40, to indicate the importance of the failure of the AddPhone job. The default is 5.
Retrieve SNMP configuration data for these phones?	Select **Yes** to retrieve SNMP configuration data for these phones. The default is unchecked. If you select **Yes**, you can run the addPhone script without first running the RetrieveConfigData script. If you do not select **Yes**, you must run RetreiveConfigData before running AddPhone.
Configuration Settings	
List of phone extensions	Provide a list of the extension numbers of the Avaya phones that you want to monitor. You can type one extension, a list of extensions, or a list of extension ranges. Separate multiple extensions with a comma. For example: `20001-20040,30001-30050,40000` **NOTE:** If you have many extension numbers, you can list the extensions in a separate file and then use the following parameter to access that file.

Parameter	How to Set It

Full path to file with list of phone extensions	If you have many extensions to monitor, you can type the full path to a file that contains a list of the phone extensions. Each extension or range of extensions in the file should be on a separate line. For example:
	`20001-20040`
	`30001-30050`
	`40000`
	Because the file must be accessible from the AppManager agent, the path must be a local directory on the proxy computer or a UNC path.
	Important If you type a UNC path, then the `netiqmc` service must be running as a user that has access to the path.

Event Notification	
Raise event if all phones are added successfully?	Select **Yes** to raise an event if the specified phones are successfully added to the TreeView pane. The default is Yes.
Event severity when phones are added successfully	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the specified phones are added successfully. The default is 25.
Raise event if configuration retrieval succeeds?	Select **Yes** to raise an event if the Knowledge Script successfully retrieved SNMP configuration information for these phones. The default is unselected.
Event severity when the configuration retrieval succeeds	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the Knowledge Script successfully retrieved SNMP configuration information for these phones. The default is 25.

13.3 Announcements

Use this Knowledge Script to monitor announcements for queued calls, calls that dropped while in queue, and peak usage of announcement ports.

Choose whether to monitor specific announcements or the top *n* announcements. This script raises an event if a threshold is exceeded. In addition, this script generates data streams for calls queued, calls dropped, and peak port usage.

NOTE: This script does not support Communication Manager version 3.1.

13.3.1 Resource Object

AvayaCM Announcement object

13.3.2 Default Schedule

By default, this script runs every hour.

13.3.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Job Failure Notification	
Event severity when job fails	Set the event severity level, from 1 to 40, to indicate the importance of the failure of the Announcements job. The default is 5.
Select monitor type	Select one of the following monitoring options: • **Top-N** — select to monitor *n* announcements with the highest values for queued calls, dropped calls, or peak port usage. If you select this option, provide the value for *n* in the *Number of announcements to monitor* parameter. • **Comma-separated** — select to monitor specific announcements. If you select this option, provide a list of announcement extensions in the *Comma-separated list of announcements to monitor* parameter.
Number of announcements to monitor	Specify the number of announcements you want to monitor. The default is 5.
Comma-separated list of announcement extensions	Provide a list of the announcement extensions you want to monitor. You can provide individual extension numbers, a range of extension numbers, or a combination of both. For example: `20001-20020,20055,20100-20200` Separate each number or range with a comma.

Parameter	How to Set It
Enable use of SNMP GETBulk requests?	By default, this parameter is enabled, allowing the Announcements Knowledge Script job to access Communication Manager MIBs using `GETNext` and `GETBulk` SNMP requests, as appropriate. Disable this parameter to allow the script to use only `GETNext` requests. Not all MIB tables are extensive enough to need a `GETBulk` request. A `GETBulk` request is faster, but more CPU-intensive than a `GETNext` request.
Number of rows to request for each GETBulk operation	Specify the number of rows from the MIB table to return in a `GETBulk` request. The default is 10 rows. The number of rows determines how much faster MIB data is returned. If CPU usage is too high, you can reduce the number of rows per `GETBulk` request or disable the *Enable use of SNMP GETBulk requests?* parameter.
Interval to pause between GETBulk requests	Specify the number of milliseconds to wait between GETBulk requests. The default is 100 milliseconds. The amount of delay can help with managing CPU usage and speed of SNMP requests. For example, a one-row `GETBUlk` with a 100-millisecond delay between requests executes more slowly and uses less CPU than a `GETNext` request.
Monitor Calls Queued	
Event Notification	
Raise event if number of calls queued exceeds threshold?	Select **Yes** to raise an event if the number of calls in queue for an announcement exceeds the threshold you set. The default is Yes.
Threshold - Maximum calls queued	Specify the highest number of calls that can be in queue for an announcement before an event is raised. The default is 0 calls.
Event severity when number of calls queued exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of calls in queue for an announcement exceeds the threshold. The default is 15.
Data Collection	
Collect data for calls queued?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the number of calls in queue for an announcement during the monitoring period. The default is Yes.
Monitor Calls Dropped	
Event Notification	
Raise event if number of calls dropped exceeds threshold?	Select **Yes** to raise an event if the number of calls dropped while in queue exceeds the threshold you set. The default is Yes.
Threshold - Maximum calls dropped	Specify the highest number of calls that can be dropped while in queue before an event is raised. The default is 0 calls.
Event severity when number of calls dropped exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of calls dropped while in queue exceeds the threshold. The default is 15.
Data Collection	

Parameter	How to Set It
Collect data for calls dropped?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the number of calls dropped while in queue during the monitoring period. The default is unselected.
Monitor Peak Ports Used	
Event Notification	
Raise event if peak number of ports used exceeds threshold?	Select **Yes** to raise an event if the number of ports in use simultaneously exceeds the threshold you set. The default is Yes.
Threshold - Maximum peak ports used	Specify the highest number of ports that can be in use simultaneously before an event is raised. The default is 12 ports.
Event severity when peak number of ports used exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of ports in use simultaneously exceeds the threshold. The default is 15.
Data Collection	
Collect data for peak ports used?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the highest number of ports in use simultaneously during the monitoring period. The default is Yes.

13.4 AttendantCalls

Use this Knowledge Script to monitor an active switch processing element (SPE) for statistics related to call attendants. This script raises an event if a monitored value exceeds the threshold you set. In addition, this script generates data streams for the following statistics:

- Answered calls
- Calls abandoned before being answered
- Calls abandoned while on hold
- Calls placed on hold
- Queued calls
- Number of minutes attendants are active
- Average call answer time

13.4.1 Resource Object

AvayaCM Active SPE object

13.4.2 Default Schedule

By default, this script runs every hour because the SNMP data it monitors is updated only once an hour. If you change the schedule to a shorter interval, you may receive SNMP request errors until the SNMP data is repopulated.

13.4.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Job Failure Notification	
Event severity when job fails	Set the event severity level, from 1 to 40, to indicate the importance of the failure of the AttendantCalls job. The default is 5.
Monitor Answered Calls	
Event Notification	
Raise event if number of answered calls exceeds threshold?	Select **Yes** to raise an event if the number of calls answered by attendants exceeds the threshold you set. The default is Yes.
Threshold - Maximum number of answered calls	Specify the maximum number of calls that can be answered by attendants before an event is raised. The default is 100 calls.
Event severity when number of answered calls exceeds threshold	Set the severity level, from 1 to 40, to indicate the importance of an event in which the number of answered calls exceeds the threshold. The default is 15.

Parameter	How to Set It
Data Collection	
Collect data for number of answered calls?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the number of calls answered by attendants during the monitoring period. The default is Yes.
Monitor Calls Abandoned Before Answered	
Event Notification	
Raise event if number of calls abandoned before answered exceeds threshold?	Select **Yes** to raise an event if the number of abandoned calls exceeds the threshold you set. The default is Yes. A call is considered abandoned when the caller hangs up before the call is answered.
Threshold - Maximum number of calls abandoned before answered	Specify the maximum number of calls that can be abandoned before an event is raised. The default is 10 calls.
Event severity when number of calls abandoned before answered exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of abandoned calls exceeds the threshold. The default is 10.
Data Collection	
Collect data for number of calls abandoned before answered?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the number of calls that were abandoned before being answered by an attendant. The default is unselected.
Monitor Calls Abandoned While on Hold	
Event Notification	
Raise event if number of calls abandoned while on hold exceeds threshold?	Select **Yes** to raise an event if the number of calls that were abandoned while on hold exceeds the threshold you set. The default is Yes.
Threshold - Maximum number of calls abandoned while on hold	Specify the maximum number of on-hold calls that can be abandoned before an event is raised. The default is 10 calls.
Event severity when number of calls abandoned while on hold exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of calls that were abandoned while on hold exceeds the threshold. The default is 10.
Data Collection	
Collect data for number of calls abandoned before answered?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the number of calls that were abandoned before being answered by an attendant. The default is unselected.
Monitor Calls on Hold	
Event Notification	
Raise event if number of calls on hold exceeds threshold?	Select **Yes** to raise an event if the number of calls that were placed on hold exceeds the threshold you set. The default is Yes.
Threshold - Maximum number of calls on hold	Specify the maximum number of calls that can be placed on hold before an event is raised. The default is 100 calls.

Parameter	How to Set It
Event severity when number of calls on hold exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of calls that were placed on hold exceeds the threshold. The default is 15.
Data Collection	
Collect data for number of calls on hold?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the number of calls that were placed on hold during the monitoring period. The default is Yes.
Monitor Queued Calls	
Event Notification	
Raise event if number of queued calls exceeds threshold?	Select **Yes** to raise an event if the number of calls in queue for an available attendant exceeds the threshold you set. The default is Yes.
Threshold - Maximum number of queued calls	Specify the maximum number of calls that can be in queue before an event is raised. The default is 100 calls.
Event severity when number of queued calls exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of calls in queue for an available attendant exceeds the threshold. The default is 15.
Data Collection	
Collect data for number of queued calls?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the number of calls in queue during the monitoring period. The default is Yes.
Monitor Time Attendants are Active	
Event Notification	
Raise event if time attendants are active exceeds threshold?	Select **Yes** to raise an event if the number of minutes in which attendants are active (on a call) exceeds the threshold you set. The default is Yes.
Threshold - Maximum time attendants are active	Specify the maximum number of minutes attendants can be active before an event is raised. The default is 15 minutes.
Event severity when time attendants are active exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of minutes that attendants are active exceeds the threshold. The default is 15.
Data Collection	
Collect data for time attendants are active?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the number of minutes in which attendants were active during the monitoring period. The default is Yes.
Monitor Average Answer Time	
Event Notification	
Raise event if average answer time exceeds threshold?	Select **Yes** to raise an event if the average number of minutes that attendants take to answer calls exceeds the threshold you set. The default is Yes.
Threshold - Maximum average answer time	Specify the highest average number of minutes it can take attendants to answer calls before an event is raised. The default is 5 minutes.
Event severity when answer time exceeds threshold	Select the event severity level, from 1 to 40, to indicate the importance of an event in which the average number of minutes it takes for attendants to answer calls exceeds the threshold. The default is 15.
Data Collection	

Parameter	How to Set It
Collect data for answer time?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the average number of minutes that attendants took to answer calls during the monitoring period. The default is Yes.

13.5 CallActivity

Use this Knowledge Script to monitor call activity on selected Communication Managers. This script raises an event if a threshold is exceeded. In addition, this script generates data streams for the number of active calls and the number of completed calls.

When you start the CallActivity Knowledge Script job, the managed object begins collecting call detail records (CDRs) to store in the Avaya CM supplemental database. After the CallActivity job stops, the managed object continues to collect CDRs. CDR collection stops within a time period equal to two intervals of the job, but never less than 4 minutes after the CallActivity job stops.

13.5.1 Prerequisite

Run SetupSupplementalDB to create the Avaya CM supplemental database.

13.5.2 Resource Object

AvayaCM Active SPE object

13.5.3 Default Schedule

By default, this script runs every 5 minutes.

13.5.4 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Job Failure Notification	
Event severity when job fails	Set the event severity level, from 1 to 40, to indicate the importance of the failure of the CallActivity job. The default is 5.
Monitor Active Calls	
Event Notification	
Raise event if number of active calls exceeds threshold?	Select **Yes** to raise an event if the number of active calls exceeds the threshold you set. The default is Yes.
Threshold - Number of active calls	Specify the maximum number of calls that can be active before an event is raised. The default is 100 calls.
Event severity when number of active calls exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of active calls exceeds the threshold. The default is 15.
Data Collection	

Parameter	How to Set It
Collect data for number of active calls?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the number of calls that were active during the monitoring period. The default is Yes.
Monitor Completed Calls	
Event Notification	
Raise event if number of completed calls exceeds threshold?	Select **Yes** to raise an event if the number of completed calls exceeds the threshold you set. The default is Yes.
Threshold - Number of completed calls	Specify the maximum number of calls that can be completed before an event is raised. The default is 100 calls.
Event severity when number of completed calls exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of completed calls exceeds the threshold. The default is 15.
Data Collection	
Collect data for number of completed calls?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the number of calls that were completed during the monitoring period. The default is Yes.

13.6 CallFailures

Use this Knowledge Script to monitor call detail records (CDRs) in the Avaya CM supplemental database for calls that terminated with abnormal condition codes. You can indicate which condition codes should not be considered abnormal. This script raises an event if the number of failed calls exceeds the threshold or if the supplemental database contains no records. In addition, this script generates data streams for the number of failed calls.

When you start the CallFailures Knowledge Script job, the managed object begins collecting CDRs to store in the supplemental database. After the CallFailures job stops, the managed object continues to collect CDRs. CDR collection stops within a time period equal to two intervals of the job, but never less than 4 minutes after the CallFailures job stops.

The purpose of this script is twofold:

- **Monitoring**. In monitoring mode, this script checks the CDR tables at each specified interval for new records that match your query. In the first iteration of the job, this script finds the last record in the CDR table and checks back one interval from there. In subsequent iterations, this script checks for new records that match the query in each interval.
- **Troubleshooting**. In troubleshooting mode, this script runs once and checks the CDR tables for calls that disconnected within the range you select in the *Select call disconnect time range* parameter. Select **Run once** on the Schedule tab to run this script in troubleshooting mode. However, the managed object does not collect CDRs unless this script is running, which could pose a problem should you want to troubleshoot a call that occurred 5 minutes ago, for example. Therefore, to perform troubleshooting as needed, run this script as a separate job with data collection and events disabled, and set the schedule to run every *n* minutes. By doing so, the supplemental database will always contain data you can use for troubleshooting.
- **Diagnosing**. In diagnostic mode, this script works in conjunction with NetIQ Vivinet Diagnostics to diagnose VoIP quality problems detected during monitoring. If a call quality threshold is exceeded, then, by default, this script launches Action_DiagnoseVoIPQuality, a Knowledge Script that in turn launches Vivinet Diagnostics to generate a diagnosis of the problem.

  To turn off diagnostic mode, click the Actions tab, select **Action_DiagnoseVoIPQuality**, and click **Delete**. Turning diagnostic mode off or on does not affect the events raised by this script.

13.6.1 Prerequisite

Run SetupSupplementalDB to create the Avaya CM supplemental database.

13.6.2 Condition Codes

The following table identifies all supported condition codes:

Condition Code	Description
0	An intraswitch call, which originates and terminates on the switch
1 (A)	An attendant-handled call or an attendant-assisted call, except conference calls

Condition Code	Description
4 (D)	An extremely long call or a call with an extremely high message count TSC. An extremely long call is one that lasts for 10 or more hours. An extremely high message count TSC is 9999 or more messages. When a call exceeds 10 hours, the system creates a call record with this condition code and a duration of 9 hours, 59 minutes, and 1-9 tenths of a minute. The system creates a similar call record with this condition code after each succeeding 10-hour period. When the call terminates, the system creates a final call record with a different condition code that identifies the type of call.
6 (E)	A call the system did not record because system resources were unavailable. The CDR record includes the time and the duration of the outage. The system generates this condition code for: • Calls that the system routes to the attendant • Calls that require the CDR feature to overwrite records • ISDN calls that are not completed at the far end, if the Q.931 message indicates the reason that the call was not completed. The system does not generate the condition code for ISDN calls that receive inband tones.
7 (G)	Calls that use the AAR or ARS feature.
8 (H)	Calls that are served on a delayed basis by the Ringback Queuing feature.
9 (I)	An incoming call, a tandem call, an incoming NCA-TSC call, or a tandem NCA-TSC call
A	An outgoing call
B	An adjunct-placed outgoing call
C (L)	A conference call For trunk CDR, the system create a separate call record, with this condition code, for each incoming or outgoing trunk that is used during the conference call. If you disable ITCS and OTCS, the system records the extension of the originator of the conference call. The system does not record any other extension. If you disable ITCS, and you administer the originator of the conference call to use Intraswitch CDR, the system generates a call with this condition code whenever the originator of the conference dials a nontrunk conference participant. If ITCS is active, and you do not administer the originator of the conference call to use Intraswitch CDR, the system generates a call with this condition code whenever the originator of the conference dials an intraswitch conference participant.
E (N)	A call that the system does not complete because the following facilities to complete the call are unavailable: • Outgoing calls - The trunks are busy and no queue exists. - The trunks are busy and the queue is full. • Incoming calls - The extension is busy. - The extension is unassigned. This condition code also identifies an ISDN Call By Call Service Selection call that is unsuccessful because of an administered trunk usage allocation plan. Incoming trunk calls to a busy telephone do not generate a CDR record.

Condition Code	Description
F	A call that the system does not complete because of one of the following conditions: • The originator of the call has insufficient calling privileges. • An NSF mismatch occurs for an ISDN call. • An authorization mismatch occurs for a data call.
G	A call that the system terminates to a ringing station
H	Notes that the system abandoned a ring call
I	A call that the system terminates to a busy station
J	An incoming trunk call that is a new connection that uses Additional Network Feature-Path Replacement (ANF-PR) or DCS with Rerouting. For more information, see the *Administrator Guide for Avaya Communication Manager*.
K	An outgoing trunk call that is a new connection that uses ANF-PR or DCS with Rerouting. For more information, see the *Administrator Guide for Avaya Communication Manager*.
M	An outgoing trunk call that the system disconnects because the call exceeds the time allowed.
T	CDR records for calls that meet the following conditions: • The **Condition Code 'T' for Redirected Calls?** field on the CDR System Parameters screen is set to **y**. • The incoming trunk group is direct inward dialing (DID). • The system automatically redirects an incoming call off of the server.

13.6.3 Resource Object

AvayaCM Active SPE object

13.6.4 Default Schedule

By default, this script runs every 5 minutes.

13.6.5 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Job Failure Notification	
Event severity when job fails	Set the event severity level, from 1 to 40, to indicate the importance of the failure of the CallFailures job. The default is 5.

Parameter	How to Set It
Include call details?	Select **Yes** to include call details in the events raised by this script. Leave this parameter unselected to suppress the following call details: • Condition Code • Calling Number • Called Number • Connect Time • Disconnect Time • Duration **NOTE:** If you configured Communication Manager to use Agent ID numbers, an event will identify an Agent ID or gateway, rather than a called or calling phone extension.
Raise event if no records found?	Select **Yes** to raise an event if there are no CDRs to monitor. This does not mean there are no CDRs with abnormal condition codes. Instead, it means there are no CDRs at all. The default is unselected.
Event severity when no records found	Set the event severity level, from 1 to 40, to indicate the importance of an event in which no CDRs were found. The default is 25.
Query Filters	No matter how many calls match the filters you select, an event displays only the first 50 calls.
Exclude these failure codes	Provide a comma-separated list of the condition codes you do not want to monitor.
Exclude these failure codes on zero duration calls only	Provide a comma-separated list of the condition codes you do not want to monitor, but only for calls that have a duration of zero.
Include only these FRL codes	Provide a comma-separated list of the Facilities Restriction Level (FRL) codes you want to use as filters. Leave this field blank to include all FRL codes. **NOTE:** To avoid an error message, run the SetupSupplementalDB Knowledge Script once before running this script. Also, set up FRL at the Avaya System Access Terminal (SAT) interface before running this script. Do not use FRL at the Avaya SAT interface with previous versions of this module.
Minimum duration	Set this parameter to filter out records whose call duration is less than the specified value. Accept the default of 0 to ignore the filter for minimum call duration.
Maximum duration	Set this parameter to filter out records whose call duration is greater than or equal to the specified value. Accept the default of 0 to ignore the filter for maximum call duration.
Calling phone number	Specify the number of the calling phone you want to find in the CDRs. Wildcard characters are acceptable. Leave this parameter blank to search for any calling phone number. **NOTE:** If you configured Communication Manager to use Agent ID numbers, an event will identify the Agent ID or gateway associated with the *Calling phone number* you enter here.
Phone number connector	Set this parameter only if you specify both a *Calling phone number* and a *Called phone number*. Your selection indicates how the script will connect the two parameters: AND or OR. The default is AND.

Parameter	How to Set It
Called phone number	Specify the number of the called phone you want to find in the CDRs. Wildcard characters are acceptable. Leave this parameter blank to search for any called phone number. **NOTE:** If you configured Communication Manager to use Agent ID numbers, an event will identify the Agent ID or gateway associated with the *Called phone number* you enter here.
Troubleshooting	
Call disconnect time range	Select a **Specific** or **Sliding** date/time range for which the query should search for data. The default time range is fixed at 24 hours. **NOTE:** This parameter is valid only when you select **Run once** on the Schedule tab.
Monitor Failed Calls	
Event Notification	
Raise event if number of failed calls exceeds threshold?	Select **Yes** to raise an event if the number of calls that failed with an abnormal condition code exceeds the threshold you set. The default is Yes.
Threshold - Maximum number of failed calls	Specify the maximum number of calls that can fail before an event is raised. The default is 0 calls.
Event severity when number of failed calls exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of failed calls exceeds the threshold. The default is 15.
Data Collection	
Collect data for number of failed calls?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the number of calls that failed with an abnormal condition code during the monitoring period. The default is unselected.

13.7 CallQuality

Use this Knowledge Script to monitor RTCP packets in the Avaya CM supplemental database for call quality statistics: jitter, latency, packet loss, MOS (Mean Opinion Score), and R-Value. This script raises an event if a monitored value exceeds or falls below a threshold. MOS and R-Value are computed only for calls that use one of the following codecs: G.711u, G.711a, or G.729.

NOTE: You can trigger NetIQ Vivinet Diagnostics to diagnose the problem indicated by an event in which the percentage lost data threshold is exceeded. For more information, see "Triggering Call and Phone Quality Diagnoses" on page 3932.

When you start the CallQuality Knowledge Script job, the managed object begins collecting RTCP packets to store in the Avaya CM supplemental database. After the CallQuality job stops, the managed object continues to collect packets. Packet collection stops within a time period equal to two intervals of the job, but never less than 4 minutes after the CallQuality job stops.

The purpose of this script is twofold:

- **Monitoring**. In monitoring mode, this script checks the supplemental database tables at each specified interval for new records that match your query. In the first iteration of the job, this script finds the last record in a table and checks back one interval from there. In subsequent iterations, this script checks for new records that match the query in each interval.
- **Troubleshooting**. In troubleshooting mode, this script runs once and checks the supplemental database for calls that disconnected within the range you select in the *Select call disconnect time range* parameter. Select **Run once** on the Schedule tab to run this script in troubleshooting mode. However, the managed object does not collect RTCP packets unless this script is running, which could pose a problem should you want to troubleshoot a call that occurred 5 minutes ago, for example. Therefore, to perform troubleshooting as needed, run this script as a separate job with data collection and events disabled, and set the schedule to run every *n* minutes. By doing so, the Avaya CM supplemental database will always contain data you can use for troubleshooting.
- **Diagnosing**. In diagnostic mode, this script works in conjunction with NetIQ Vivinet Diagnostics to diagnose VoIP quality problems detected during monitoring. If a call quality threshold is exceeded, then, by default, this script launches Action_DiagnoseVoIPQuality, a Knowledge Script that in turn launches Vivinet Diagnostics to generate a diagnosis of the problem.

  To turn off diagnostic mode, click the **Actions** tab, select **Action_DiagnoseVoIPQuality**, and click **Delete**. Turning diagnostic mode off or on does not affect the events raised by this script.

13.7.1 Understanding data streams and Threshold Events

This script generates data streams for average MOS, R-Value, jitter, latency (one-way delay), and packet loss. These average values are based on data from each phone involved in calls that completed during the script's interval, which is, by default, every 5 minutes. For example, in a given call, the calling phone's jitter was 30 milliseconds and the called phone's jitter was 75 milliseconds. For this call, the data stream would be a calculated average of the jitter for both phones: 52.5 milliseconds.

This calculated average is below the default threshold value of 60 milliseconds. However, AppManager raises threshold events based on values for each phone in a call, not on the average value. Therefore, for this call, AppManager would raise one event based on the 75 milliseconds of jitter for the called phone.

13.7.2 Prerequisite

Run SetupSupplementalDB to create the Avaya CM supplemental database.

13.7.3 Resource Object

AvayaCM Active SPE object

13.7.4 Default Schedule

By default, this script runs every 5 minutes.

13.7.5 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Job Failure Notification	
Event severity when job fails	Set the event severity level, from 1 to 40, to indicate the importance of the failure of the CallQuality job. The default is 5.
Include call details?	Select **Yes** to include call details in the events raised by this script. Leave this parameter unselected to suppress the following call details: • Caller and Called Average MOS • Caller and Called Average R-Value • Caller and Called Jitter • Caller and Called Latency • Caller and Called Lost Packets • Caller and Called Codec • Caller and Called Number • Connect Time • Disconnect Time • Duration **NOTE:** If you configured Communication Manager to use Agent ID numbers, an event will identify an Agent ID or gateway, rather than a called or calling phone extension.
Raise event if no records found?	Select **Yes** to raise an event if there are no RTCP packets to monitor in the Avaya CM supplemental database. This does not mean there are no records with call quality data. It means there are no records at all. The default is unselected.
Event severity when no records found	Set the event severity level, from 1 to 40, to indicate the importance of an event in which no RTCP packets were found. The default is 25.
Query Filters	No matter how many calls match the filters you select, an event displays only the first 50 calls.
Maximum table size	Specify the maximum number of detail rows to include in an event message. The default is 50 rows.
Minimum duration	Use this parameter to filter out records whose call duration is less than the value you specify. Accept the default of 0 seconds to ignore the filter for minimum duration.

Parameter	How to Set It
Maximum table size	Specify the maximum number of rows of results to include in the call quality tables shown in the details of an event message. The default is 25 rows.
Maximum duration	Use this parameter to filter out records whose call duration is greater than or equal to the value you specify. Accept the default of 0 seconds to ignore the filter for maximum duration.
Calling phone number	Specify the number of the calling phone you want to find in the supplemental database. Wildcard characters are acceptable. Leave this parameter blank to search for any calling phone number. **NOTE:** If you configured Communication Manager to use Agent ID numbers, an event will identify the Agent ID or gateway associated with the *Calling phone number* you enter here.
Phone number connector	Set this parameter only if you specify both a *Calling phone number* and a *Called phone number*. Your selection indicates how the script will connect the two parameters: AND or OR. The default is AND.
Called phone number	Specify the number of the called phone you want to find in the supplemental database. Wildcard characters are acceptable. Leave this parameter blank to search for any called phone number. **NOTE:** If you configured Communication Manager to use Agent ID numbers, an event will identify the Agent ID or gateway associated with the *Called phone number* you enter here.
Device name	Use this parameter to query for those calls whose device name matches the specified value. Wildcard characters are acceptable. Leave this parameter blank to search for any device name.
Troubleshooting	
Call disconnect time range	Select a range of time and dates in which the query should search for data in the supplemental database. • Select **Fixed Time** to select specific days and times that the query should begin and end. • Select **Sliding** to select a number of hours, days, months, or years in which to search. The query starts its search at the time the job runs, and goes back through the supplemental database for the number of units you select. The default is Fixed Time. **NOTE:** This parameter is valid only when you select **Run once** on the Schedule tab.
Monitor Average MOS	
Event Notification	
Raise event if average MOS falls below threshold?	Select **Yes** to raise an event if the average MOS value falls below the threshold. The default is Yes.
Threshold - Average MOS	Specify the lowest average MOS value that must occur to prevent an event from being raised. The default is 3.60.
Event severity when average MOS falls below threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the average MOS value falls below the threshold. The default is 5.
Data Collection	
Collect data for average MOS?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the average MOS value during the monitoring period. The default is unselected.

Parameter	How to Set It
Monitor Average R-Value	
Event Notification	
Raise event if average R-Value falls below threshold?	Select **Yes** to raise an event if the average R-Value falls below the threshold. The default is Yes.
Threshold - Average R-Value	Specify the lowest average R-Value that must occur to prevent an event from being raised. The default is 70.
Event severity when average R-Value falls below threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the average R-Value falls below the threshold. The default is 5.
Data Collection	
Collect data for average R-Value?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the average R-Value during the monitoring period. The default is unselected.
Monitor Average Jitter	
Event Notification	
Raise event if jitter exceeds threshold?	Select **Yes** to raise an event if the jitter value exceeds the threshold. The default is Yes.
Threshold - Maximum jitter	Specify the highest average jitter value that can occur before an event is raised. The default is 60 milliseconds.
Event severity when jitter exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the jitter value exceeds the threshold. The default is 15.
Data Collection	
Collect data for jitter?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the amount of jitter that occurred during the monitoring period. The default is unselected.
Monitor Average Latency	
Event Notification	
Raise event if latency exceeds threshold?	Select **Yes** to raise an event if the latency value exceeds the threshold. The default is Yes.
Threshold - Maximum latency	Specify the highest amount of average latency that can occur before an event is raised. The default is 400 milliseconds.
Event severity when latency exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the latency value exceeds the threshold. The default is 15.
Data Collection	
Collect data for latency?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the amount of latency that occurred during the monitoring period. The default is unselected.
Monitor Average Packet Loss	
Event Notification	
Raise event if packet loss exceeds threshold?	Select **Yes** to raise an event if the packet loss value exceeds the threshold. The default is Yes.
Threshold - Maximum packet loss	Specify the highest percentage of average packet loss that can occur before an event is raised. The default is 1%.

Parameter	How to Set It
Event severity when packet loss exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the packet loss value exceeds the threshold. The default is 15.
Data Collection	
Collect data for packet loss?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the percentage of packet loss that occurred during the monitoring period. The default is unselected.

13.7.6 Triggering Call and Phone Quality Diagnoses

You can use NetIQ Vivinet Diagnostics to diagnose problems identified by AvayaCM Knowledge Scripts.

Using the existing methodology of launching an Action script based on an event, AppManager can launch Action_DiagnoseVoIPQuality to trigger Vivinet Diagnostics to diagnose the problem for events raised by the following Knowledge Scripts:

- **AvayaCM_CallQuality** events trigger Vivinet Diagnostics to diagnose the problem when average MOS, average R-Value, average jitter, average latency, and average packet loss fall below or exceed their thresholds.
- **AvayaCM_PhoneQuality** events trigger Vivinet Diagnostics to diagnose the problem when MOS, R-Value, jitter, latency, and packet loss fall below or exceed their thresholds during the data collection interval.

The Action script runs by default only if Vivinet Diagnostics 2.3 or later is installed on the computer on which the script is running.

To trigger Vivinet Diagnostics:

1. When setting parameter values for the PhoneQuality or CallQuality scripts, click the **Actions** tab. Action_DiagnoseVoIPQuality is selected by default.
2. Click **Properties** and enter values for all parameters for the Action script. For more information about the parameter values, click **Help** on the Properties for Action_DiagnoseVoIPQuality dialog box.

For more information about Vivinet Diagnostics and call quality diagnoses, see the *User Guide for Vivinet Diagnostics* and the Help for the Action_DiagnoseVoIPQuality Knowledge Script.

13.8 CallQuery

Use this Knowledge Script to search for call detail records (CDRs) retrieved from Communication Manager and stored in the Avaya CM supplemental database. The search is based on query filters you select. This script raises an event if no CDRs are found or if the number of CDRs found exceeds the threshold you set. In addition, this script generates a data stream for the number of records found.

When you start the CallQuery Knowledge Script job, the managed object begins collecting CDRs to store in the Avaya CM supplemental database. After the CallQuery job stops, the managed object continues to collect CDRs. CDR collection stops within a time period equal to two intervals of the job, but never less than 4 minutes after the CallQuery job stops.

The purpose of this script is twofold:

- **Monitoring**. In monitoring mode, this script checks the CDR tables at each specified interval for new records that match your query. In the first iteration of the job, this script finds the last record in the CDR table and checks back one interval from there. In subsequent iterations, this script checks for new records that match the query in each interval.
- **Troubleshooting**. In troubleshooting mode, this script runs once and checks the CDR tables for calls that disconnected within the range you select in the *Select call disconnect time range* parameter. Select **Run once** on the Schedule tab to run this script in troubleshooting mode. However, the managed object does not collect CDRs unless this script is running, which could pose a problem should you want to troubleshoot a call that occurred 5 minutes ago, for example. Therefore, to perform troubleshooting as needed, run this script as a separate job with data collection and events disabled, and set the schedule to run every *n* minutes. By doing so, the Avaya CM supplemental database will always contain data you can use for troubleshooting.

13.8.1 Prerequisite

Run SetupSupplementalDB to create the Avaya CM supplemental database.

13.8.2 Resource Object

AvayaCM Active SPE object

13.8.3 Default Schedule

By default, this script runs every 5 minutes.

13.8.4 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Job Failure Notification	

Parameter	How to Set It
Event severity when job fails	Set the event severity level, from 1 to 40, to indicate the importance of the failure of the CallQuery job. The default is 5.
Include call details?	Select **Yes** to include call details in the events raised by this script. Leave this parameter unselected to suppress the following call details: • Condition Code • Calling Number • Called Number • Connect Time • Disconnect Time • Duration (seconds)
Raise event if no records found?	Select **Yes** to raise an event if there are no CDRs to monitor. This does not mean there are no CDRs with call quality data. It means there are no CDRs at all. The default is unselected.
Event severity when no records found	Set the event severity level, from 1 to 40, to indicate the importance of an event in which no CDRs were found. The default is 25.
Query Filters	No matter how many calls match the filters you select, an event displays only the first 50 calls.
Maximum table size	Specify the maximum number of detail rows to include in an event message. The default is 50 rows.
Minimum duration	Set this parameter to filter out records whose call duration is less than the specified value. Accept the default of 0 to ignore the filter for minimum call duration.
Maximum duration	Set this parameter to filter out records whose call duration is greater than or equal to the specified value. Accept the default of 0 to ignore the filter for maximum call duration.
Calling phone number	Specify the number of the calling phone you want to find in the CDRs. Wildcard characters are acceptable. Leave this parameter blank to search for any calling phone number. **NOTE:** If you configured Communication Manager to use Agent ID numbers, an event will identify the Agent ID or gateway associated with the *Calling phone number* you enter here.
Phone number connector	Set this parameter only if you specify both a *Calling phone number* and a *Called phone number*. Your selection indicates how the script will connect the two parameters: AND or OR. The default is AND.
Called phone number	Specify the number of the called phone you want to find in the CDRs. Wildcard characters are acceptable. Leave this parameter blank to search for any called phone number. **NOTE:** If you configured Communication Manager to use Agent ID numbers, an event will identify the Agent ID or gateway associated with the *Called phone number* you enter here.
Originating device name	Set this parameter to query for those calls whose originating device name matches the specified value. Wildcard characters are acceptable. Leave this parameter blank to search for any originating device name.
Device name connector	Set this parameter ONLY if you specify both an Originating device name and a Destination device name. Your selection indicates how the script will connect the two parameters: AND or OR. The default is AND.

Parameter	How to Set It
Destination device name	Set this parameter to query for those calls whose destination device name matches the specified value. Wildcard characters are acceptable. Leave this parameter blank to search for any destination device name.
Troubleshooting	
Call disconnect time range	Select a **Specific** or **Sliding** date/time range for which the query should search for data. The default time range is fixed at 24 hours. **NOTE:** This parameter is valid only when you select **Run once** on the Schedule tab.
Monitor Records Found	
Event Notification	
Raise event if number of records exceeds threshold?	Select **Yes** to raise an event if the number of CDRs found exceeds the threshold. The default is Yes.
Threshold - Maximum number of records	Specify the maximum number of CDRs that can be found before an event is raised. The default is 0 CDRs.
Event severity when number of records exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of CDRs found exceeds the threshold. The default is 15.
Data Collection	
Collect data for number of records?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the number of CDRs found during the monitoring period.

13.9 CPU_Usage

Use this Knowledge Script to monitor a Communication Manager server for system management CPU usage, operating system CPU usage, call-processing CPU usage, and available CPU. Note that "available CPU" is the amount of CPU that is available for high-priority tasks, including CPU allocated for low-priority tasks. "Available CPU" is not the amount of CPU that is left over after system management, operating system, and call processing take their shares. Therefore, the four CPU usage values provided by this script can total more than 100%.

This script raises events when values exceed or fall below thresholds that you set. In addition, this script generates data streams for all monitored metrics.

13.9.1 Resource Object

AvayaCM Active SPE object

13.9.2 Default Schedule

By default, this script runs every 2 minutes.

13.9.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Job Failure Notification	
Event severity when job fails	Set the event severity level, from 1 to 40, to indicate the importance of the failure of the CPU_Usage job. The default is 5.
Monitor Call Processing CPU Usage	
Event Notification	
Raise event if call processing CPU usage exceeds threshold?	Select **Yes** to raise an event if the percentage of CPU used by call processing exceeds the threshold you set. The default is Yes.
Threshold - Maximum call processing CPU usage	Specify the maximum amount of CPU that call processing can use before an event is raised. The default is 80%.
Event severity when call processing CPU usage exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the percentage of CPU used by call processing exceeds the threshold. The default is 15.
Data Collection	
Collect data for call processing CPU usage?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the percentage of CPU used by call processing for the monitoring period. The default is Yes.
Monitor System Management CPU Usage	

Parameter	How to Set It
Event Notification	
Raise event if system management CPU usage exceeds threshold?	Select **Yes** to raise an event if the percentage of CPU used by system management processes exceeds the threshold you set. The default is Yes.
Threshold - Maximum system management CPU usage	Specify the maximum percentage of CPU that system management processes can use before an event is raised. The default is 20%.
Event severity when system management CPU usage exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the percentage of CPU used by system management processes exceeds the threshold. The default is 15.
Data Collection	
Collect data for system management CPU usage?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the percentage of CPU used by system management processes for the monitoring period. The default is unselected.
Monitor Operating System CPU Usage	
Event Notification	
Raise event if operating system CPU usage exceeds threshold?	Select **Yes** to raise an event if the percentage of CPU used by operating system processes exceeds the threshold you set. The default is Yes.
Threshold - Maximum operating system CPU usage	Specify the maximum percentage of CPU that operating system processes can use before an event is raised. The default is 20%.
Event severity when operating system CPU usage exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the percentage of CPU used by operating system processes exceeds the threshold. The default is 15.
Data Collection	
Collect data for operating system CPU usage?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the percentage of CPU used by operating system processes for the monitoring period. The default is unselected.
Monitor Available CPU	
Event Notification	
Raise event if available CPU falls below threshold?	Select **Yes** to raise an event if the percentage of CPU that is available for Communication Manager falls below the threshold you set. The default is Yes.
Threshold - Minimum available CPU	Specify the minimum amount of CPU that must be available for Communication Manager before an event is raised. The default is 20%.
Event severity when available CPU falls below threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which available CPU falls below the threshold. The default is 15.
Data Collection	
Collect data for available CPU?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the percentage of available CPU for the monitoring period. The default is unselected.

13.10 ESS_Status

Use this Knowledge Script to monitor the registration status of an Avaya Enterprise Survivable Server (ESS). An ESS allows a media server to be used as a backup controller to protect Communication Manager against catastrophic failure.

This script raises an event if the server deregisters or reregisters. In addition, this script generates a data point for server registration status: 0 for deregistered and 1 for reregistered.

13.10.1 Resource Object

AvayaCM ESS object

13.10.2 Default Schedule

By default, this script runs every 5 minutes.

13.10.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Job Failure Notification	
Event severity when job fails	Set the event severity level, from 1 to 40, to indicate the importance of the failure of the ESS_Status job. The default is 5.
Monitor Registration Status	
Data Collection	
Collect data for registration status?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns a 0 if the ESS deregisters and a 1 if the ESS reregisters. The default is unselected.
Event Notification	
Raise event if server deregisters?	Select **Yes** to raise an event if the ESS deregisters from Communication Manager. The default is Yes.
Event severity when server deregisters	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the ESS deregisters from Communication Manager. The default is 15.
Raise event if server reregisters?	Select **Yes** to raise an event if the ESS reregisters with Communication Manager. The default is Yes.
Event severity when server reregisters	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the ESS reregisters with Communication Manager. The default is 25.

13.11 H248GatewayStatus

Use this Knowledge Script to monitor the status of H.248 media gateways, including the following items:

- Major alarms
- Minor alarms
- Warning alarms
- Status of H.248 (server to gateway) link

This script raises an event if a threshold is exceeded. In addition, this script generates data streams for each monitored value.

13.11.1 Resource Object

AvayaCM H.248 Media Gateway object

13.11.2 Default Schedule

By default, this script runs every 5 minutes.

13.11.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Job Failure Notification	
Event severity when job fails	Set the event severity level, from 1 to 40, to indicate the importance of the failure of the H248GatewayStatus job. The default is 5.
Monitor Major Alarms	
Event Notification	
Raise event if number of major alarms exceeds threshold?	Select **Yes** to raise an event if the number of major alarms exceeds the threshold you set. The default is Yes.
Threshold - Maximum major alarms	Specify the highest number of major alarms that can occur before an event is raised. The default is 1 alarm.
Event severity when number of major alarms exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of major alarms exceeds the threshold. The default is 5.
Data Collection	
Collect data for major alarms?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the number of major alarms that occurred during the monitoring period. The default is Yes.

Parameter	How to Set It
Monitor Minor Alarms	
Event Notification	
Raise event if number of minor alarms exceeds threshold?	Select **Yes** to raise an event if the number of minor alarms exceeds the threshold you set. The default is Yes.
Threshold - Maximum minor alarms	Specify the highest number of minor alarms that can occur before an event is raised. The default is 5 alarms.
Event severity when number of minor alarms exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of minor alarms exceeds the threshold. The default is 10.
Data Collection	
Collect data for minor alarms?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the number of minor alarms that occurred during the monitoring period. The default is Yes.
Monitor Warning Alarms	
Event Notification	
Raise event if number of warning alarms exceeds threshold?	Select **Yes** to raise an event if the number of warning alarms exceeds the threshold you set. The default is Yes.
Threshold - Maximum warning alarms	Specify the highest number of warning alarms that can occur before an event is raised. The default is 10 alarms.
Event severity when number of warning alarms exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of warning alarms exceeds the threshold. The default is 15.
Data Collection	
Collect data for warning alarms?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the number of warning alarms that occurred during the monitoring period. The default is unselected.
Monitor H.248 Link Status	
Event Notification	
Raise event if H.248 link is down?	Select **Yes** to raise an event if the H.248 link is unavailable. The default is Yes.
Event severity when H.248 link is down	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the H.248 link is unavailable.
Data Collection	
Collect data for link status?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns 0 if the link is up or 1 if the link is down. The default is Yes.

13.12 HuntGroupUsage

Use this Knowledge Script to monitor the status of hunt groups. This script raises an event if a monitored value exceeds the threshold you set. In addition, this script generates data streams for the following statistics:

- Number of answered calls
- Number of queued calls
- Number of abandoned calls
- Average call wait time

13.12.1 Resource Object

AvayaCM Hunt Group object

13.12.2 Default Schedule

By default, this script runs every hour because the SNMP data it monitors is updated only once an hour. If you change the schedule to a shorter interval, you may receive SNMP request errors until the SNMP data is repopulated.

13.12.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Job Failure Notification	
Event severity when job fails	Set the event severity level, from 1 to 40, to indicate the importance of the failure of the HuntGroupUsage job. The default is 5.
Monitor Answered Calls	
Event Notification	
Raise event if number of answered calls exceeds threshold?	Select **Yes** to raise an event if the number of calls answered in the hunt group exceeds the threshold you set. The default is Yes.
Threshold - Maximum number of answered calls	Specify the highest number of calls that can be answered in the hunt group before an event is raised. The default is 100 calls.
Event severity when number of answered calls exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of calls answered in the hunt group exceeds the threshold. The default is 15.
Data Collection	
Collect data for number of answered calls?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the number of calls answered in the hunt group during the monitoring period. The default is Yes.

Parameter	How to Set It
Monitor Abandoned Calls	
Event Notification	
Raise event if number of abandoned calls exceeds threshold?	Select **Yes** to raise an event if the number of calls abandoned in the hunt group exceeds the threshold you set. The default is Yes. A call is considered abandoned when the caller hangs up before the call is answered.
Threshold - Maximum number of abandoned calls	Specify the highest number of calls that can be abandoned before an event is raised. The default is 5 calls.
Event severity when number of abandoned calls exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of abandoned calls exceeds the threshold. The default is 15.
Data Collection	
Collect data for number of abandoned calls?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the number of calls that were abandoned during the monitoring period. The default is unselected.
Monitor Queued Calls	
Event Notification	
Raise event if number of queued calls exceeds threshold?	Select **Yes** to raise an event if the number of calls in queue exceeds the threshold you set. The default is Yes.
Threshold - Maximum number of queued calls	Specify the highest number of calls that can be in queue before an event is raised. The default is 100 calls.
Event severity when number of queued calls exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of calls in queue exceeds the threshold. The default is 15.
Data Collection	
Collect data for queued calls?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the number of calls that were in queue during the monitoring period. The default is Yes.
Monitor Average Call Wait Time	
Event Notification	
Raise event if average call wait time exceeds threshold?	Select **Yes** to raise an event if the average amount of call wait time exceeds the threshold you set. The default is Yes. Call wait time is the amount of time a call waits before being answered.
Threshold - Maximum average call wait time	Specify the highest amount of average wait time that calls can experience before an event is raised. The default is 1 minute.
Event severity when average call wait time exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the average amount of call wait time exceeds the threshold. The default is 15.
Data Collection	
Collect data for average call wait time?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the average amount of wait time that calls experienced during the monitoring period. The default is unselected.

13.13 LSP_Status

Use this Knowledge Script to monitor the registration status of an Avaya Local Survivable Processor (LSP). An LSP allows a media server to be a survivable call-processing server for remote and branch customer locations.

This script raises an event if the processor deregisters or reregisters. In addition, this script generates a data point for processor registration status: 0 for deregistered and 1 for reregistered.

13.13.1 Resource Object

AvayaCM LSP object

13.13.2 Default Schedule

By default, this script runs every 5 minutes.

13.13.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Job Failure Notification	
Event severity when job fails	Set the event severity level, from 1 to 40, to indicate the importance of the failure of the LSP_Status job. The default is 5.
Monitor Registration Status	
Data Collection	
Collect data for registration status?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns a 0 if the LSP deregisters and a 1 if the LSP reregisters. The default is unselected.
Event Notification	
Raise event if processor deregisters?	Select **Yes** to raise an event if the LSP deregisters from Communication Manager. The default is Yes.
Event severity when processor deregisters	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the LSP deregisters from Communication Manager. The default is 15.
Raise event if processor reregisters?	Select **Yes** to raise an event if the LSP reregisters with Communication Manager The default is Yes.
Event severity when processor reregisters	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the LSP reregisters with Communication Manager. The default is 25.

13.14 PhoneConnectivity

Use this Knowledge Script to monitor disconnected registered phones for a Communication Manager and to maintain a history of the monitored phones in the Avaya CM supplemental database. This script raises an event if the number or percentage of disconnected registered phones exceeds the threshold you set. You can group events by cluster, building, floor, or type of phone.

13.14.1 Prerequisites

- Run SetupSupplementalDB to create the Avaya CM supplemental database.
- Run RetrieveConfigData to populate the Avaya CM supplemental database.

13.14.2 Resource Object

AvayaCM_ActiveSPE

13.14.3 Default Schedule

By default, this script runs every 10 minutes.

13.14.4 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Job Failure Notification	
Event severity when job fails	Set the event severity level, from 1 to 40, to indicate the importance of the failure of the PhoneConnectivity job. The default is 5.
Enable use of SNMP GETBulk requests?	By default, this parameter is enabled, allowing the PhoneConnectivity Knowledge Script job to access Communication Manager MIBs using `GETNext` and `GETBulk` SNMP requests, as appropriate. Disable this parameter to allow the script to use only `GETNext` requests. Not all MIB tables are extensive enough to need a `GETBulk` request. A `GETBulk` request is faster, but more CPU-intensive than `GETNext`.
Number of rows to request for each GETBulk operation	Specify the number of rows from the MIB table to return in a `GETBulk` request. The default is 10 rows. The number of rows determines how much faster MIB data is returned. If CPU usage is too high, you can reduce the number of rows per `GETBulk` or disable the *Enable use of SNMP GETBulk requests?* parameter.

Parameter	How to Set It
Interval to pause between GETBulk requests	Specify the number of milliseconds to wait between GETBulk requests. The default is 100 milliseconds. The amount of delay can help manage CPU usage and speed of SNMP requests. For example, a one-row `GETBulk` with a 100-millisecond delay between requests runs more slowly and uses less CPU than a `GETNext` request.
Event Notification	
Raise event if disconnected registered phones in group exceed threshold?	Select **Yes** to raise an event if the number or percentage of disconnected registered phones in a group exceeds the threshold you set. The default is Yes. Use *Type of threshold* to create a “number” or “percentage” event. Use *Select event grouping* to select how to group the deregistered phones.
Select event grouping	Select whether to group disconnected registered phones by **Cluster**, **Building**, **Floor,** or **Type** of phone. AppManager raises an event when the number or percentage of phones in *each* group exceeds the threshold you set. For example, suppose the following were true: • You set *Maximum number of disconnected registered phones in the group* to “5” • You set *Select event grouping* to “Building,” and you have three buildings. If AppManager detects six disconnected registered phones in the first building, two in the second, and seven in the third, it will raise two events: one for the six disconnected registered phones in the first building and another for the seven disconnected registered phones in the third building. Because you set the threshold to “5,” no event is raised for the disconnected registered phones in the second building. The default is Cluster.
Type of threshold	Select whether you want to raise events based on the **Number** or **Percent** of disconnected registered phones. The default is Number.
Threshold - Maximum number of disconnected registered phones	Use this parameter if you selected **Number** in *Type of threshold*. Specify the maximum number of registered phones that can be disconnected before an event is raised. The default is 0 phones.
Threshold - Maximum percent of disconnected registered phones	Use this parameter if you selected **Percent** in *Type of threshold*. Specify the maximum percentage of registered phones that can be disconnected before an event is raised. The default is 0%.
Event severity when disconnected registered phones exceed threshold	Set the event severity, from 1 to 40, to indicate the importance of an event in which the number or percentage of disconnected registered phones in a group exceeds the threshold you set. The default is 15.
Include phone details in event message?	Select **Yes** to include details of the disconnected registered phones in the event message. Phone details can include station extension, station name, building, floor, station type, room, cable, jack, port, and deregistration time. The default is Yes.
Maximum number of detail rows to include in event message	Use this parameter if you selected **Yes** in *Include deregistered phone details in event message*. Specify the maximum number of detail rows to include in an event message. Each row contains details for one phone. Rows are sorted by most recently disconnected phone. Specify “0” to include all rows. The default is 20 rows.

13.15 PhoneDeregistrations

Use this Knowledge Script to monitor phone deregistrations for Communication Manager and to maintain deregistration history in the Avaya CM supplemental database. This script raises an event if the number or percentage of deregistered phones exceeds the threshold you set. You can group events by building, floor, or type of phone.

13.15.1 Prerequisites

- Run SetupSupplementalDB to create the Avaya CM supplemental database.
- Run RetrieveConfigData to populate the Avaya CM supplemental database.

13.15.2 Resource Object

AvayaCM Active SPE object

13.15.3 Default Schedule

By default, this script runs every 10 minutes.

13.15.4 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Job Failure Notification	
Event severity when job fails	Set the event severity level, from 1 to 40, to indicate the importance of the failure of the PhoneDeregistrations job. The default is 5.
Enable use of SNMP GETBulk requests?	By default, this parameter is enabled, allowing the PhoneDeregistrations job to use `GETNext` and `GETBulk` SNMP requests to access Communication Manager MIBs. Disable this parameter to allow the script to use only `GETNext` requests. Not all MIB tables are extensive enough to need a `GETBulk` request. A `GETBulk` request is faster, but more CPU-intensive than `GETNext`.
Number of rows to request for each GETBulk operation	Specify the number of rows from the MIB table to return in a `GETBulk` request. The default is 10 rows. The number of rows determines how quickly MIB data is returned. If CPU usage is too high, you can reduce the number of rows per `GETBulk` or disable the *Enable use of SNMP GETBulk requests?* parameter.

Parameter	How to Set It
Interval to pause between GETBulk operations	Specify the number of milliseconds to wait between GETBulk requests. The default is 100 milliseconds. The amount of delay can help with managing CPU usage and speed of SNMP requests. For example, a one-row `GETBulk` with a 100-millisecond delay between requests executes more slowly and uses less CPU than a `GETNext` request.
Event Notification	
Raise event if deregistered phones in group exceed threshold?	Select **Yes** to raise an event if the number or percentage of deregistered phones in a group exceeds the threshold you set. The default is Yes. Use *Type of threshold* to create a “number” or “percentage” event. Use *Select event grouping* to select how to group the deregistered phones.
Select event grouping	Select whether to group deregistered phones by **Cluster**, **Building**, **Floor,** or **Type** of phone. AppManager raises an event when the number or percentage of deregistered phones in *each* group exceeds the threshold you set. For example, suppose the following were true: • You set *Maximum number of deregistered phones in the group* to “5.” • You set *Select event grouping* to “Building,” and you have three buildings. If AppManager detects six deregistered phones in the first building, two in the second, and seven in the third, it will raise two events: one for the six deregistered phones in the first building and another for the seven deregistered phones in the third building. Because you set the threshold to “5,” no event is raised for the deregistered phones in the second building. The default is Cluster.
Type of threshold	Select whether you want to raise events based on the **Number** or **Percent** of deregistered phones. The default is Number.
Threshold - Maximum number of deregistered phones	Use this parameter if you selected **Number** in *Type of threshold*. Specify the maximum number of phones that can be deregistered before an event is raised. The default is 0 phones.
Threshold - Maximum percent of deregistered phones	Use this parameter if you selected **Percent** in *Type of threshold*. Specify the maximum percentage of phones that can be deregistered before an event is raised. The default is 0%.
Event severity when deregistered phones exceed threshold	Set the event severity, from 1 to 40, to indicate the importance of an event in which the number or percentage of deregistered phones in a group exceeds the threshold you set. The default is 15.
Include deregistered phone details in event message?	Select **Yes** to include details of the deregistered phones in the event message. Phone details can include station extension, station name, building, floor, station type, room, cable, jack, port, and deregistration time. The default is Yes.
Maximum number of detail rows to include in event message	Use this parameter if you selected **Yes** in *Include deregistered phone details in event message*. Specify the maximum number of detail rows to include in an event message. Each row contains details for one phone. Rows are sorted by most recently deregistered phone. Specify “0” to include all rows. The default is 20 rows.

13.16 PhoneInventory

Use this Knowledge Script to create an inventory of the phones configured in a Communication Manager cluster. You choose both the search criteria for the inventory and the location of the output folder for the results file containing the inventory list. Unless you specify a UNC path, `\\servername\sharename\directoryname\filename`, the results file is written to the computer on which the NetIQ AppManager agent is running. If you specify a UNC path, ensure the `NetIQmc` service is running as an account that has proper permissions on the UNC path.

13.16.1 Resource Object

AvayaCM Active SPE object

13.16.2 Default Schedule

By default, this script runs once.

13.16.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Job Failure Notification	
Event severity when job fails	Set the event severity level, from 1 to 40, to indicate the importance of the failure of the PhoneInventory job. The default is 5.
Enable use of SNMP GETBulk requests?	By default, this parameter is enabled, allowing the PhoneInventory job to use `GETNext` and `GETBulk` SNMP requests to access Communication Manager MIBs. Disable this parameter to allow the script to use only `GETNext` requests. Not all MIB tables are extensive enough to need a `GETBulk` request. A `GETBulk` request is faster, but more CPU-intensive than `GETNext`.
Number of rows to request for each GETBulk operation	Specify the number of rows from the MIB table to return in a `GETBulk` request. The default is 10 rows. The number of rows determines how quickly MIB data is returned. If CPU usage is too high, you can reduce the number of rows per `GETBulk` or disable the *Enable use of SNMP GETBulk requests?* parameter.

Parameter	How to Set It
Interval to pause between GETBulk operations	Specify the number of milliseconds to wait between GETBulk requests. The default is 100 milliseconds. The amount of delay can help with managing CPU usage and speed of SNMP requests. For example, a one row `GETBulk` with a 100-millisecond delay between requests executes more slowly and uses less CPU than a `GETNext` request.
Raise event if phone inventory succeeds?	Select **Yes** to raise an event when a phone inventory file is successfully generated. The default is Yes.
Event severity when phone inventory succeeds	Set the event severity level, from 1 to 40, to indicate the importance of an event in which an inventory file is successfully generated. The default is 25.
Raise event if no records found?	Select **Yes** to raise an event when the PhoneInventory job finds no phones based on the criteria you selected. The default is Yes.
Event severity when no records found	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the PhoneInventory job found no phones based on the criteria you selected. The default is 25.
Search Options	
Select by	Select the filter by which you want to create the list of phones. • Name • Extension (the default) • Building • Floor • Type
Selection criteria	Type the selection criteria for the phones to be listed. You can specify the actual item or you can specify a pattern by using the * wildcard. For example, to monitor all the phones in the ADM building, enter `ADM*`. You can enter multiple items by separating each item with a comma. For example: `ADM0009A*,ADM0009B*` The items you enter must be of the same type as the *Select by* parameter. So if *Select by* is Name, then the items you enter must be device names or patterns. If *Select by* is Extension, then the items you enter must be phone extension numbers. **NOTE:** Only the following characters are acceptable in this parameter: • Number • Uppercase and lowercase letters • Periods • Commas • Asterisks (*) • Underscores • Spaces

Parameter	How to Set It
List only phones with status of	To further filter the list of phones, select a status. Only phones with this status that also match the criteria you specified in *Selection criteria* and *Select by* will be included in the inventory list. Select from the following status types: • Any • Registered • Registered Not Connected • Unregistered
Result File Options	
Full path to output folder for result file	Type the full path or a UNC path to a location on the agent computer in which to save the inventory `.csv` file. The default path is `c:\Program Files\NetIQ\Temp\NetIQ_Debug\PhoneInventory.csv`
Order by	Select **Name** to display the contents of the results file in order by phone name. Select **Extension** to display the contents of the results file in order by phone extension number. The default is Extension.

13.17 PhoneQuality

Use this Knowledge Script to collect real-time voice-quality statistics for active calls on Avaya IP phones. This script raises one event per call if statistics exceed or fall below the thresholds you set. In addition, this script generates data streams for the following statistics:

- Maximum interval MOS
- Maximum interval R-Value MOS and R-Value are computed only for calls that use one of the following codecs: G.711u, G.711a, or G.729.
- Maximum interval jitter
- Maximum interval latency
- Maximum interval packet loss

NOTE: You can trigger NetIQ Vivinet Diagnostics to diagnose the problem when voice quality thresholds are exceeded. For more information, see "Triggering Call and Phone Quality Diagnoses" on page 3932.

When you start the PhoneQuality Knowledge Script job, the managed object begins collecting voice quality statistics. The managed object stops collecting statistics approximately one minute after the PhoneQuality job stops. If you attempt to delete a phone on which collection is still occurring, the following event is raised:

```
The phone(s) could not be removed because one or more phones are currently
being monitored by the PhoneQuality Knowledge Script.  You must stop the
PhoneQuality job(s) before removing the phones.
```

NOTE: Unlike other proxy-based AppManager modules, AppManager for Avaya Communication Manager supports only one AppManager repository (`QDB`) per proxy agent computer. This limitation ensures the accuracy of monitoring phones with the PhoneQuality script. The list of phones for monitoring with this script does not differentiate between repositories; if multiple repositories were allowed, you could very well monitor the wrong set of phones for a given repository.

13.17.1 Prerequisite

Run AddPhone to add phones to be monitored. The PhoneQuality script is not available until after you run the AddPhone script.

13.17.2 Resource Object

AvayaCM Station object

NOTE: Do not monitor more than 100 active phone (station) objects in one cluster or across multiple clusters.

13.17.3 Default Schedule

By default, this script runs on an asynchronous schedule.

13.17.4 Setting Parameter Values

Set the following parameters as needed:

Description	How To Set It
General Settings	
Job Failure Notification	
Event severity when job fails	Set the event severity level, from 1 to 40, to indicate the importance of the failure of the PhoneQuality job. The default is 5.
Monitor Settings	
Data collection interval for voice quality metrics	Specify the interval at which data points are generated for voice quality metrics. The default is 30 seconds. The minimum is 15 seconds. **NOTE:** Communication Manager sends RTCP packets to the proxy computer in almost real-time. If your data collection interval is the default, 30 seconds, and you are monitoring 100 phones and collecting data for only one metric, such as MOS, AppManager will generate about three data points per second (100 phones / 30 seconds). With all five metrics enabled, AppManager will generate about 16 data points per second. If you change to a more frequent data collection interval, for example every 15 seconds, AppManager will generate about 32 data points per second.
Additional fixed delay for MOS/R-Value calculation	Enter an amount of delay (in milliseconds) that you want to add to a call. This delay is in addition to the three other types of delay associated with calculating MOS and R-Value: • Network delay in one direction. • Packetization delay. This value is fixed, based on the type of codec being used. • Jitter buffer delay. This value is fixed, based on the type and size of the jitter buffer being used. The default is 0 milliseconds.
Monitor Interval MOS	
Event Notification	
Raise event if interval MOS falls below threshold?	Select **Yes** to raise an event if the value of interval MOS falls below the threshold that you set. The default is Yes. Interval MOS is the MOS value measured *during* the data collection interval you set. It is not the MOS value at the instance of data collection.
Threshold - Minimum interval MOS	Specify the lowest interval MOS value that can be calculated before an event is raised. The default is 3.60.
Event severity when interval MOS falls below threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the interval MOS value falls below the threshold you set. The default is 5.
Data Collection	
Collect data for interval MOS?	Select **Yes** to collect interval MOS data for charts and graphs. When enabled, data collection returns the value of interval MOS measured during the data collection interval. The default is Yes.
Monitor Interval R-Value	
Event Notification	
Raise event if interval R-Value falls below threshold?	Select **Yes** to raise an event if interval R-Value falls below the threshold that you set. The default is Yes. Interval R-Value is the R-Value measured *during* the data collection interval you set. It is not the R-Value at the instance of data collection.

Description	How To Set It
Threshold - Minimum interval R-value	Enter the lowest interval R-Value that can be calculated before an event is raised. The default is 70.
Event severity when interval R-value falls below threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which interval R-Value falls below the threshold you set. The default is 5.
Data Collection	
Collect data for interval R-Value?	Select **Yes** to collect interval R-Value data for charts and graphs. When enabled, data collection returns the value of interval R-Value measured during the data collection interval. The default is unselected.
Monitor Interval Jitter	
Event Notification	
Raise event if interval jitter exceeds threshold?	Select **Yes** to raise an event if the amount of interval jitter exceeds the threshold that you set. The default is Yes. Interval jitter is the jitter value measured *during* the data collection interval you set. It is not the jitter value at the instance of data collection.
Threshold - Maximum interval jitter	Specify the highest amount of interval jitter that can be achieved before an event is raised. The default is 60 milliseconds.
Event severity when interval jitter exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the amount of interval jitter exceeds the threshold you set. The default is 15.
Data Collection	
Collect data for interval jitter?	Select **Yes** to collect interval jitter data for charts and graphs. When enabled, data collection returns the value of interval jitter measured during the data collection interval. The default is unselected.
Monitor Interval Latency	
Event Notification	
Raise event if interval latency exceeds threshold?	Select **Yes** to raise an event if the amount of interval latency exceeds the threshold that you set. The default is Yes. Interval latency is the latency value measured *during* the data collection interval you set. It is not the latency value at the instance of data collection.
Threshold - Maximum interval latency	Specify the highest amount of interval latency that can be achieved before an event is raised. The default is 400 milliseconds.
Event severity when interval latency exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the amount of interval latency exceeds the threshold you set. The default is 15.
Data Collection	
Collect data for interval latency?	Select **Yes** to collect interval latency data for charts and graphs. When enabled, data collection returns the value of interval latency measured during the data collection interval. The default is unselected.
Monitor Interval Packet Loss	
Event Notification	

Description	How To Set It
Raise event if interval packet loss exceeds threshold?	Select **Yes** to raise an event if the percentage of interval packet loss exceeds the threshold that you set. The default is Yes. Interval packet loss is the percentage of packet loss measured *during* the data collection interval you set. It is not the packet loss value at the instance of data collection.
Threshold - Maximum interval packet loss	Specify the highest percentage of interval packet loss that can occur before an event is raised. The default is 1.0%.
Event severity when interval packet loss exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the percentage of interval packet loss exceeds the threshold you set. The default is 15.
Data Collection	
Collect data for interval packet loss?	Select **Yes** to collect interval packet loss data for charts and graphs. When enabled, data collection returns the percentage of interval packet loss measured during the data collection interval. The default is unselected.

13.18 RegisteredResources

Use this Knowledge Script to monitor changes in the number of resources registered to a Communication Manager server. Resources include IP stations, remote office stations, attendant consoles, and H.248 media gateways. This script raises an event when a threshold is exceeded. In addition, this script generates data streams for the following statistics:

- Number of registered IP stations
- Percentage of increase and decrease in number of registered IP stations
- Number of registered IP attendant consoles
- Percentage of increase and decrease in number of registered IP attendant consoles
- Number of registered remote office stations
- Percentage of increase and decrease in number of registered remote office stations
- Number of registered H.248 media gateways
- Percentage of increase and decrease in number of registered H.248 media gateways

13.18.1 Resource Object

AvayaCM Active SPE object

13.18.2 Default Schedule

By default, this script runs every 5 minutes.

13.18.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Job Failure Notification	
Event severity when job fails	Set the event severity level, from 1 to 40, to indicate the importance of the failure of the RegisteredResources job. The default is 5.
Monitor Registered IP Stations	
Data Collection	
Collect data for registered IP stations?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the number of IP stations that were registered during the monitoring period. The default is Yes.
Monitor Increase in Registered IP Stations	
Event Notification	

Parameter	How to Set It
Raise event if increase in registered IP stations exceeds threshold?	Select **Yes** to raise an event if the percentage of increase in registered IP stations exceeds the threshold you set. The default is Yes.
Threshold - Maximum increase in registered IP stations	Specify the highest percentage of increase in registered IP stations that can occur before an event is raised. The default is 10%.
Event severity when increase in registered IP stations exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the percentage of increase in registered IP stations exceeds the threshold. The default is 15.
Data Collection	
Collect data for increase in registered IP stations?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the percentage of increase in registered IP stations during the monitoring period. The default is unselected.
Monitor Decrease in Registered IP Stations	
Event Notification	
Raise event if decrease in registered IP stations exceeds threshold?	Select **Yes** to raise an event if the percentage of decrease in registered IP stations exceeds the threshold you set. The default is Yes.
Threshold - Maximum decrease in registered IP stations	Specify the highest percentage of decrease in registered IP stations that can occur before an event is raised. The default is 10%.
Event severity when decrease in registered IP stations exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the percentage of decrease in registered IP stations exceeds the threshold. The default is 15.
Data Collection	
Collect data for decrease in registered IP stations?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the percentage of decrease in registered IP stations during the monitoring period. The default is unselected.
Monitor Registered IP Attendant Consoles	
Data Collection	
Collect data for registered IP attendant consoles?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the number of IP attendant consoles that were registered during the monitoring period. The default is Yes.
Monitor Increase in Registered IP Attendant Consoles	
Event Notification	
Raise event if increase in registered IP attendant consoles exceeds threshold?	Select **Yes** to raise an event if the percentage of increase in registered IP attendant consoles exceeds the threshold you set. The default is Yes.
Threshold - Maximum increase in registered IP attendant consoles	Specify the highest percentage of increase in registered IP attendant consoles that can occur before an event is raised. The default is 10%.
Event severity when increase in registered IP attendant consoles exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the percentage of increase in registered IP attendant consoles exceeds the threshold. The default is 15.

Parameter	How to Set It
Data Collection	
Collect data for increase in registered IP attendant consoles?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the percentage of increase in registered IP attendant consoles during the monitoring period. The default is unselected.
Monitor Decrease in Registered IP Attendant Consoles	
Event Notification	
Raise event if decrease in registered IP attendant consoles exceeds threshold?	Select **Yes** to raise an event if the percentage of decrease in registered IP attendant consoles exceeds the threshold you set. The default is Yes.
Threshold - Maximum decrease in registered IP attendant consoles	Specify the highest percentage of decrease in registered IP attendant consoles that can occur before an event is raised. The default is 10%.
Event severity when decrease in registered IP attendant consoles exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the percentage of decrease in registered IP attendant consoles exceeds the threshold. The default is 15.
Data Collection	
Collect data for decrease in registered IP attendant consoles?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the percentage of decrease in registered IP attendant consoles during the monitoring period. The default is unselected.
Monitor Registered Remote Office Stations	
Data Collection	
Collect data for registered remote office stations?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the number of remote office stations that were registered during the monitoring period. The default is Yes.
Monitor Increase in Registered Remote Office Stations	
Event Notification	
Raise event if increase in registered remote office stations exceeds threshold?	Select **Yes** to raise an event if the percentage of increase in registered remote office stations exceeds the threshold you set. The default is Yes.
Threshold - Maximum increase in registered remote office stations	Specify the highest percentage of increase in registered remote office stations that can occur before an event is raised. The default is 10%.
Event severity when increase in registered remote office stations exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the percentage of increase in registered remote office stations exceeds the threshold. The default is 15.
Data Collection	
Collect data for increase in registered remote office stations?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the percentage of increase in registered remote office stations during the monitoring period. The default is unselected.
Monitor Decrease in Registered Remote Office Stations	
Event Notification	

Parameter	How to Set It
Raise event if decrease in registered remote office stations exceeds threshold?	Select **Yes** to raise an event if the percentage of decrease in registered remote office stations exceeds the threshold you set. The default is Yes.
Threshold - Maximum decrease in registered remote office stations	Specify the highest percentage of decrease in registered remote office stations that can occur before an event is raised. The default is 10%.
Event severity when decrease in registered remote office stations exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the percentage of decrease in registered remote office stations exceeds the threshold. The default is 15.
Data Collection	
Collect data for decrease in registered remote office stations?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the percentage of decrease in registered remote office stations during the monitoring period. The default is unselected.
Monitor Registered H.248 Media Gateways	
Data Collection	
Collect data for registered H.248 media gateways?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the number of H.248 media gateways that were registered during the monitoring period. The default is Yes.
Monitor Increase in Registered H.248 Media Gateways	
Event Notification	
Raise event if increase in registered H.248 media gateways exceeds threshold?	Select **Yes** to raise an event if the percentage of increase in registered H.248 media gateways exceeds the threshold you set. The default is Yes.
Threshold - Maximum increase in registered H.248 media gateways	Specify the highest percentage of increase in registered H.248 media gateways that can occur before an event is raised. The default is 10%.
Event severity when increase in registered H.248 media gateways exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the percentage of increase in registered H.248 media gateways exceeds the threshold. The default is 15.
Data Collection	
Collect data for increase in registered H.248 media gateways?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the percentage of increase in registered H.248 media gateways during the monitoring period. The default is unselected.
Monitor Decrease in Registered H.248 Media Gateways	
Event Notification	
Raise event if decrease in registered H.248 media gateways exceeds threshold?	Select **Yes** to raise an event if the percentage of decrease in registered H.248 media gateways exceeds the threshold you set. The default is Yes.
Threshold - Maximum decrease in registered H.248 media gateways	Specify the highest percentage of decrease in registered H.248 media gateways that can occur before an event is raised. The default is 10%.

Parameter	How to Set It
Event severity when decrease in registered H.248 media gateways exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the percentage of decrease in registered H.248 media gateways exceeds the threshold. The default is 15.
Data Collection	
Collect data for decrease in registered H.248 media gateways?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the percentage of decrease in registered H.248 media gateways during the monitoring period. The default is unselected.

13.19 RemovePhone

Use this Knowledge Script to remove Avaya IP phone objects from the TreeView in the AppManager console. This script raises an event when phones are removed successfully.

TIP:

- After running this script on the object you want to remove, double-check your selection in the Objects tab. By specifically selecting a phone object from the Objects tab, you will not accidentally remove a phone that you want to keep.
- Before removing a phone, stop any monitoring jobs that are running on the phone.

13.19.1 Resource Object

AvayaCM Station object

13.19.2 Default Schedule

By default, this script runs once.

13.19.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How To Set It
General Settings	
Job Failure Notification	
Event severity when job fails	Set the event severity level, from 1 to 40, to indicate the importance of the failure of the RemovePhone job. The default is 5.
Event Notification	
Raise event if phones are removed successfully?	Select **Yes** to raise an event if the selected phone objects are successfully removed from the TreeView. The default is Yes.
Event severity when phones are removed successfully	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the selected phone objects are successfully removed from the TreeView. The default is 25.

13.20 RetrieveConfigData

Use this Knowledge Script to retrieve configuration data about stations and gateways from the Communication Manager server and store it in the Avaya CM supplemental database.

13.20.1 Prerequisite

Create the supplemental database using the SetupSupplementalDB script or the *Set up supplemental database?* parameters in the Discovery_AvayaCM Knowledge Script.

13.20.2 Resource Object

AvayaCM Active SPE object

13.20.3 Default Schedule

By default, this script runs once a day, at 3 AM, in order to perform CPU-intensive functions when Communication Manager is less busy with call activity or maintenance tasks.

However, because the PhoneDeregistrations script uses the configuration data this script retrieves, this script also runs once, immediately, allowing you to use the PhoneDeregistrations script as soon as possible.

13.20.4 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Job Failure Notification	
Event severity when job fails	Set the event severity level, from 1 to 40, to indicate the importance of the failure of the RetrieveConfigData job. The default is 5.
Enable use of SNMP GETBulk requests?	By default, this parameter is enabled, allowing the RetrieveConfigData Knowledge Script job to use `GETNext` and `GETBulk` SNMP requests to access Communication Manager MIBs. Disable this parameter to allow the script to use only `GETNext` requests. Not all MIB tables are extensive enough to need a `GETBulk` request. A `GETBulk` request is faster, but more CPU-intensive than `GETNext`.
Number of rows to request for each GETBulk operation	Specify the number of rows from the MIB table to return in a `GETBulk` request. The default is 10 rows. The number of rows determines how quickly MIB data is returned. If CPU usage is too high, you can reduce the number of rows per `GETBulk` or disable the *Enable use of SNMP GETBulk requests?* parameter.

Parameter	How to Set It
Interval to pause between GETBulk operations	Specify the number of milliseconds to wait between GETBulk requests. The default is 100 milliseconds. The amount of delay can help with managing CPU usage and speed of SNMP requests. For example, a one-row `GETBulk` with a 100-millisecond delay between requests executes more slowly and uses less CPU than a `GETNext` request.
Raise event if configuration retrieval succeeds?	Select **Yes** to raise an event if the retrieval process succeeds. The default is unselected.
Event severity when configuration retrieval succeeds	Set the event severity level, from 1 to 40, to indicate the importance of an event in which retrieval succeeds. The default is 25.

13.21 RoutePatternUsage

Use this Knowledge Script to monitor the status of route patterns. This script raises an event if a monitored value exceeds the threshold you set. In addition, this script generates data streams for the following statistics:

- Number of offered calls
- Number of trunk group seizures
- Number of blocked calls
- Number of queued calls

13.21.1 Resource Object

AvayaCM_RoutePatternObject

13.21.2 Default Schedule

By default, this script runs every hour because the SNMP data it monitors is updated only once an hour. If you change the schedule to a shorter interval, you may receive SNMP request errors until the SNMP data is repopulated.

13.21.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Job Failure Notification	
Event severity when job fails	Set the event severity level, from 1 to 40, to indicate the importance of the failure of the RoutePatternUsage job. The default is 5.
Monitor Offered Calls	
Event Notification	
Raise event if number of offered calls exceeds threshold?	Set to **Yes** to raise an event if the number of calls offered to the route pattern exceeds the threshold you set. The default is Yes.
Threshold - Maximum offered calls	Specify the highest number of calls that can be offered to the route pattern before an event is raised. The default is 20 calls.
Event severity when number of offered calls exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of calls offered to the route pattern exceeds the threshold. The default is 15.
Data Collection	
Collect data for offered calls?	Set to **Yes** to collect data for charts and reports. If enabled, data collection returns the number of calls offered to the route pattern during the monitoring period. The default is Yes.

Parameter	How to Set It
Monitor Trunk Group Seizures	
Event Notification	
Raise event if number of trunk group seizures exceeds threshold?	Set to **Yes** to raise an event if the number of trunk group seizures exceeds the threshold you set. The default is Yes. A seizure is a request to set up a call path through a trunk group.
Threshold - Maximum trunk group seizures	Specify the highest number of trunk groups that can be seized before an event is raised. The default is 5 seizures.
Event severity when number of trunk group seizures exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of trunk group seizures exceeds the threshold. The default is 15.
Data Collection	
Collect data for trunk group seizures?	Set to **Yes** to collect data for charts and reports. If enabled, data collection returns the number of trunk groups that were seized during the monitoring period. The default is Yes.
Monitor Blocked Calls	
Event Notification	
Raise event if number of blocked calls exceeds threshold?	Set to **Yes** to raise an event if the number of blocked calls exceeds the threshold you set. The default is Yes. Calls are blocked from entering the route pattern when all trunk groups are busy.
Threshold - Maximum blocked calls	Specify the highest number of calls that can be blocked before an event is raised. The default is 10 calls.
Event severity when number of blocked calls exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of blocked calls exceeds the threshold. The default is 15.
Data Collection	
Collect data for blocked calls?	Set to **Yes** to collect data for charts and reports. If enabled, data collection returns the number of calls that were blocked during the monitoring period. The default is unchecked.
Monitor Queued Calls	
Event Notification	
Raise event if number of queued calls exceeds threshold?	Set to **Yes** to raise an event if the number of queued calls exceeds the threshold. The default is Yes. Calls are queued to enter the route pattern when all trunk groups are busy.
Threshold - Maximum queued calls	Specify the highest number of calls that can be in queue before an event is raised. The default is 10 calls.
Event severity when number of queued calls exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of queued calls exceeds the threshold. The default is 15.
Data Collection	
Collect data for queued calls?	Set to **Yes** to collect data for charts and reports. If enabled, data collection returns the number of calls that were queued during the monitoring period. The default is unchecked.

13.22 SecurityViolations

Use this Knowledge Script to monitor the following security violations:

- Barrier code violations
- Calls that generated authorization code violations
- Calls that generated station security code violations

Barrier codes and authorization codes provide a level of security for remote call access to such telephony components as PBXs, switch features, and trunks. Station security codes enable the Personal Station Access feature and the Extended User Administration of Redirected Calls feature.

This script raises an event if a threshold is exceeded. In addition, this script generates data streams for monitored violations.

13.22.1 Resource Object

AvayaCM Active SPE object

13.22.2 Default Schedule

By default, this script runs every 5 minutes.

13.22.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Job Failure Notification	
Event severity when job fails	Set the event severity level, from 1 to 40, to indicate the importance of the failure of the SecurityViolations job. The default is 5.
Select port type to monitor	Select the type of login port you want to monitor for security violations. Choose from the following: • All (default) • SYSAM-LCL (local port) • SYSAM-RMT (remote port) • MAINT (maintenance port) • SYS-Port (system port) • MGR1 (management terminal connection port) • NET (network controller port) • EPN (EPN maintenance EIA port) • INADS (initialization administration system port)

Parameter	How to Set It
Enable use of SNMP GETBulk requests?	By default, this parameter is enabled, allowing the SecurityViolations Knowledge Script job to use `GETNext` and `GETBulk` SNMP requests to access Communication Manager MIBs. Disable this parameter to allow the script to use only `GETNext` requests. Not all MIB tables are extensive enough to need a `GETBulk` request. A `GETBulk` request is faster, but more CPU-intensive than `GETNext`.
Number of rows to request for each GETBulk operation	Specify the number of rows from the MIB table to return in a `GETBulk` request. The default is 10 rows. The number of rows determines how quickly MIB data is returned. If CPU usage is too high, you can reduce the number of rows per `GETBulk` or disable the *Enable use of SNMP GETBulk requests?* parameter.
Interval to pause between GETBulk operations	Specify the number of milliseconds to wait between GETBulk requests. The default is 100 milliseconds. The amount of delay can help with managing CPU usage and speed of SNMP requests. For example, a one-row `GETBulk` with a 100-millisecond delay between requests executes more slowly and uses less CPU than a `GETNext` request.
Monitor Violations for Barrier Codes	
Event Notification	
Raise event if number of violations for barrier codes exceeds threshold?	Select **Yes** to raise an event if the number of security violations for barrier codes exceeds the threshold you set. The default is Yes.
Threshold - Maximum violations for barrier codes	Specify the highest number of security violations for barrier codes that can occur before an event is raised. The default is 0 violations.
Event severity when number of violations for barrier codes exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of security violations for barrier codes exceeds the threshold. The default is 15.
Data Collection	
Collect data for number of violations for barrier codes?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the number of security violations for barrier codes that occurred during the monitoring period. The default is unselected.
Monitor Violations for Authorization Codes	
Event Notification	
Raise event if number of calls that generated authorization code violations exceeds threshold?	Select **Yes** to raise an event if the number of calls that generated authorization code violations exceeds the threshold you set. The default is Yes.
Threshold - Maximum number of calls that generated authorization code violations	Specify the highest number of calls that can generate authorization code violations before an event is raised. The default is 0 calls.

Parameter	How to Set It
Event severity when the number of calls that generated authorization code violations exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of calls that generated authorization code violations exceeds the threshold. The default is 15.
Data Collection	
Collect data for the number of calls that generated authorization code violations?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the number of that generated authorization code violations during the monitoring period. The default is unselected.
Monitor Station Violations	
Event Notification	
Raise event if the number of calls that generated station violations exceeds threshold?	Select **Yes** to raise an event if the number of calls that generated station violations exceeds the threshold you set. The default is Yes.
Threshold - Maximum number of calls that generated station violations	Specify the highest number of calls that can generate station violations before an event is raised. The default is 0 calls.
Event severity when the number of calls that generated station violations exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of calls that generated station violations exceeds the threshold. The default is 15.
Data Collection	
Collect data for the number of calls that generated station violations?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the number of calls that generated station violations during the monitoring period. The default is unselected.

13.23 SetupSupplementalDB

Use this Knowledge Script to create an Avaya CM supplemental database, including the tables and stored procedures needed to store call detail records (CDRs), disconnected phone information, and deregistered phone information. In addition, this script creates a SQL Server job that removes old records from the supplemental database.

You can also create the Avaya CM supplemental database using the *Set up supplemental database?* parameters in the Discovery_AvayaCM Knowledge Script.

For more information, see "Understanding the Avaya CM Supplemental Database" on page 3936.

13.23.1 Resource Object

AvayaCM Active SPE object

13.23.2 Default Schedule

By default, this script runs once.

13.23.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Job Failure Notification	
Event severity when job fails	Set the event severity level, from 1 to 40, to indicate the importance of the failure of the SetupSupplementalDB job. The default is 5.
Raise event if database set up succeeds?	Select **Yes** to raise an event if creation of the Avaya CM supplemental database is successful. The default is unselected.
Event severity when database setup succeeds	Set the event severity level, from 1 to 40, to indicate the importance of the success of the creation of the Avaya CM supplemental database. The default is 25.
CDR Parameters	
Number of days to keep call detail records	Specify the number of days' worth of CDRs you want to keep in the Avaya CM supplemental database. Data older than what you specify is discarded. The default is 7 days.
SQL Server Information	
Local SQL Server instance name	Specify the name of the local SQL Server instance (on the proxy agent computer) in which you want to create the new Avaya CM supplemental database. Leave this parameter blank to accept the default name.

Parameter	How to Set It
Start pruning job on supplemental database?	**For all supported versions of SQL Server, except SQL Server 2005 Express**: Set to **Yes** to create a SQL job that deletes data from the supplemental database. The SQL job runs every night. Data is deleted from the supplemental database based on the value you specify in the *Number of days to keep call detail records* parameter. The default is Yes. **For SQL Server 2005 Express**: Set to **No**. The pruning job is not supported for SQL Server 2005 Express. **To manually delete data from the supplemental database**: 1. Run the following stored procedure from a command line: `osql -E -S <sql server> -n -d <database> -Q "exec dbo.Task_AvayaCM_Pruning"` where <*sql server*> is the name of the server that hosts the supplemental database, and where <`database`> is the name of the supplemental database. For example: `osql -E -S SuppDBAvaya -n -d AvayaCM_S8300-Cluster -Q "exec dbo.Task_AvayaCM_Pruning"` 2. Configure a Windows Scheduled Task to schedule pruning at an interval of your choosing. The process for configuring a Windows Scheduled Task varies according to your version of Microsoft Windows. Consult your Windows documentation for more information.

13.23.4 Understanding the Avaya CM Supplemental Database

The Avaya CM supplemental database is a Microsoft SQL Server database you create on the proxy agent computer. The supplemental database fulfills several functions.

Storage for CDRs and RTCP packets

The managed object on the proxy agent computer receives call detail records (CDRs) from Communication Manager servers and RTCP packets from phones registered to Communication Manager servers. The proxy agent computer saves the CDR and RTCP packet data to tables in the Avaya CM supplemental database. The CallActivity, CallFailures, CallQuality, and CallQuery Knowledge Scripts query the supplemental database for the data they need.

When you start the CallActivity, CallFailures, CallQuality, or CallQuery Knowledge Script job, the managed object begins collecting CDR and RTCP data to store in the Avaya CM supplemental database. After the job stops, the managed object continues to collect CDRs and packet data. Data collection stops within a time period equal to two intervals of the job, but never less than 4 minutes after the job stops.

When you create the supplemental database, you specify how long data is retained before being deleted and archived. AppManager automatically deletes CDRs older than the retention age you specify.

Storage for phone deregistration and disconnection data

The PhoneDeregistrations and PhoneConnectivity Knowledge Scripts use SNMP queries to create lists of phones that are unregistered or registered but disconnected. The scripts query the Avaya CM supplemental database, which is populated by the RetrieveConfigData script with configuration data retrieved from Communication Manager.

To create and use the supplemental database:

1. **Create the database**. Create one Avaya CM supplemental database per Communication Manager cluster you are monitoring. Use the Discovery_AvayaCM or SetupSupplementalDB Knowledge Script for this purpose.
2. **Populate the database**. Use RetrieveConfigData to retrieve configuration data from Communication Manager and save it in the Avaya CM supplemental database.
3. **Monitor the data in the database**. Use the following scripts to analyze the data in the database.
   - CallActivity monitors active and completed calls.
   - CallFailures monitors calls that ended with the condition codes you specify.
   - CallQuality monitors jitter, latency, lost data, and MOS.
   - CallQuery searches for data based on query filters you select.
   - PhoneConnectivity monitors disconnected registered phones and maintains a history of monitored phones in the supplemental database.
   - PhoneDeregistrations monitors phone deregistrations and maintains a history of phone deregistrations in the supplemental database.

13.24 SNMPTrap

Use this Knowledge Script to monitor SNMP traps forwarded from NetIQ SNMP Trap Receiver (Trap Receiver). This script raises an event when an SNMP trap is received and when Trap Receiver is unavailable or subsequently becomes available. In addition, this script generates data streams for Trap Receiver availability.

This script checks for SNMP traps in the MIB tree. You can add Management Information Bases (MIBs) to the MIB tree. For more information, see the AddMIB Knowledge Script.

Trap Receiver receives SNMP traps, filters them, and then forwards the traps to AppManager. For more information, see "Working with NetIQ SNMP Trap Receiver" on page 525.

13.24.1 Resource Object

AvayaCM Trap Receiver object

13.24.2 Default Schedule

By default, this script runs on an asynchronous schedule.

13.24.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Trap Filters	
List of trap OIDs	Use this parameter to provide a list of the OIDs (object identifiers) of the traps you want to monitor. Separate multiple OIDs with a comma. For example: `1.3.6.1.2.1.2.2.1.1.1,1.3.6.1.2.1.2.2.1.7.1`

Full path to file with list of trap OIDs	If you have many OIDs to monitor, use this parameter to identify the full path to a file that contains a list of the OIDs. Each OID in the file should be on a separate line. For example:
	`1.3.6.1.2.1.2.2.1.1.1`
	`1.3.6.1.2.1.2.2.1.7.1`
	Because the file must be accessible from the AppManager agent, the path must be a local directory on the agent computer or a UNC path. The `netiqmc` service must be running as a user that has access to the UNC path.

List of MIB subtrees	Use this parameter to monitor an OID *and* all of its subtrees. Provide a comma-separated list of the OIDs you want to monitor. For example: `1.3.6,1.3.7`

Parameter	How to Set It

Full path to file with list of MIB subtrees	If you have many subtrees to monitor, use this parameter to provide the full path to a file that contains a list of the OIDs. Each OID in the file should be on a separate line. For example:
	`1.3.6`
	`1.3.7`
	Because the file must be accessible from the AppManager agent, the path must be a local directory on the agent computer or a UNC path. The `netiqmc` service must be running as a user that has access to the UNC path.

Event Notification	
Format trap data according to SNMP version	Select the version of SNMP whose formatting should be used for trap event messages. The data provided by each format is the same; only the layout is different.
Include prefix information to format event messages for Netcool adapter?	Select **Yes** to format trap messages for use by IBM Tivoli Netcool. When this option is enabled, trap messages include tokens and separators, such as tildes ( ), that Netcool recognizes.
Raise cleared/resolved alarm event?	Select **Yes** to raise an event when the SNMP trap message contains information about a cleared or resolved alarm. The default is Yes.
Event severity when cleared/resolved alarm received	Set the severity level, from 1 to 40, to indicate the importance of an event in which the SNMP trap message contains information about a cleared or resolved alarm. The default is 25.
Raise critical alarm event?	Select **Yes** to raise an event when the SNMP trap message contains information about a critical alarm. The default is Yes.
Event severity when critical alarm received	Set the severity level, from 1 to 40, to indicate the importance of an event in which the SNMP trap message contains information about a critical alarm. The default is 5.
Raise major alarm event?	Select **Yes** to raise an event when the SNMP trap message contains information about a major alarm. The default is Yes.
Event severity when major alarm received	Set the severity level, from 1 to 40, to indicate the importance of an event in which the SNMP trap message contains information about a major alarm. The default is 10.
Raise minor alarm event?	Select **Yes** to raise an event when the SNMP trap message contains information about a minor alarm. The default is Yes.
Event severity when minor alarm received	Set the severity level, from 1 to 40, to indicate the importance of an event in which the SNMP trap message contains information about a minor alarm. The default is 15.
Raise warning alarm event?	Select **Yes** to raise an event when the SNMP trap message contains information about a warning alarm. The default is Yes.
Event severity when warning alarm received	Set the severity level, from 1 to 40, to indicate the importance of an event in which the SNMP trap message contains information about a warning alarm. The default is 15.
Raise unmapped alarm event?	Select **Yes** to raise an event when an SNMP trap is received but is not reflected in the `.CSV` mapping file. The default is Yes. Disable this parameter if you do not want to be informed about SNMP traps that are not mapped in the `.CSV` file.
Event severity when unmapped alarm received	Set the severity level, from 1 to 40, to indicate the importance of an event in which an SNMP trap is not mapped in the `.CSV` file. The default is 15.

Parameter	How to Set It
Raise Trap Receiver availability events?	Select **Yes** to raise an event when Trap Receiver becomes unavailable and when Trap Receiver becomes available once again. The default is Yes.
Event severity when Trap Receiver is unavailable	Set the severity level, from 1 to 40, to indicate the importance of an event in which Trap Receiver becomes unavailable. The default is 5.
Event severity when Trap Receiver becomes available	Set the severity level, from 1 to 40, to indicate the importance of an event in which Trap Receiver becomes available after being unavailable. The default is 25.
Data Collection	
Collect data for Trap Receiver availability?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns "1" if Trap Receiver is available and "0" if Trap Receiver is unavailable. The default is unselected.
Interval for collecting Trap Receiver availability data	Specify the frequency with which the script collects Trap Receiver availability data. The default is every 5 minutes.

13.24.4 Working with NetIQ SNMP Trap Receiver

Installation of AppManager for Avaya Communication Manager automatically installs NetIQ SNMP Trap Receiver (Trap Receiver), which runs as a service: `NetIQTrapReceiver.exe`. Trap Receiver may compete for port usage with any other trap receiver installed on the same computer.

13.24.4.1 What is NetIQ SNMP Trap Receiver?

In general, a trap receiver is an application that receives traps from SNMP agents. Trap Receiver receives, filters, and forwards SNMP traps to AppManager. When you use Trap Receiver with AppManager for Avaya Communication Manager, the SNMPTrap Knowledge Script raises events when SNMP traps are received.

13.24.4.2 What is an SNMP Trap?

Simple Network Management Protocol (SNMP) is a protocol-based system used to manage devices on TCP/IP-based networks. From devices on which an SNMP agent resides, such as routers and switches, SNMP sends unsolicited notifications, called traps, to network administrators when thresholds for certain conditions are exceeded. These conditions are defined by the vendor in a device's Management Information Base (MIB); the network administrator sets the thresholds.

Traps are composed of Protocol Data Units (PDUs). Each PDU contains the following information, organized in various ways depending on the version of SNMP in use:

- SNMP version number
- Community name of the SNMP agent
- PDU type
- Enterprise OID (object identifier), a unique number that identifies an enterprise and its system objects in the MIB
- IP address of the SNMP agent

- Generic trap type: Cold start, Warm start, Link down, Link up, Authentication failure, and Enterprise
- Specific trap type. When the Generic trap type is set to "Enterprise," a specific trap type is included in the PDU. A specific trap is one that is unique or specific to an enterprise.
- Time the event occurred
- Varbind (variable binding), a sequence of two fields that contain the OID and a value

13.24.4.3 Understanding Trap Receiver Architecture

Trap Receiver operates on a Client-Server architecture: the *Server*—the stand-alone Trap Receiver application—receives, filters, and forwards SNMP traps to the *Client*—an application that receives traps, such as AppManager. The Server may receive traps from standard UDP port 162 or from any other configured port. The Client and the Server can reside on the same computer or on separate (proxy) computers.

Communication between Client and Server is implemented as XML messages over a TCP connection. Only one Server is allowed per computer; however, several Clients are allowed per computer. Clients that are registered to the same Server share the same TCP connection. The Server TCP port should be known to all potential Clients.

13.24.4.4 Understanding the Trap Receiver Configuration File

The configuration file for Trap Receiver, `NetIQTrapReceiver.conf`, identifies the UDP and TCP ports used by Trap Receiver: the UDP port is used for receiving traps; the TCP port is used for communicating with the Client, such as AppManager or another supported NetIQ application. The configuration file also identifies the level of logging you want to use and whether port forwarding is enabled.

By default, the configuration file is installed in `[`*`installation directory`*`]\config`, and has the following format:

```
################################################################
## NetIQTrapReceiver.conf
# A configuration file for NetIQ SNMP Trap Receiver
################################################################
#########################
# TCP port
# Syntax: tcp_port [port]
# E.g. : tcp_port 2735
#########################
tcp_port 2735
#########################
# UDP port
# Syntax: udp_port [port]
# E.g. : udp_port 162
#########################
udp_port 162
#########################
# Forwarding
# Syntax: forward [address]:[port] [v1]
# E.g. : forward 127.0.0.1:1000 v1
#########################
#########################
```

```
# Log level
# Syntax: log_level error|warning|info|debug|xml
# E.g. : log_level info
########################
log_level debug
```

If the configuration file cannot be found, cannot be parsed, or does not contain one of the required values, Trap Receiver is initialized with the default configuration as shown above.

When changing values in the configuration file, take into account the following:

- If you change the TCP port number, stop all asynchronous Knowledge Script jobs associated with the modules that support Trap Receiver. Run the Discovery Knowledge Script on all monitored devices to enable the devices to recognize the new TCP port number.
- If you change the UDP port number, also change the UDP port number configured on the devices that send traps to Trap Receiver.
- If another service uses port 2735 or port 162, Trap Receiver *will not start*. The Trap Receiver log file will contain different levels of messages, based on the log_level you choose. Either change the port numbers in the configuration file, stop the service that is using the default Trap Receiver port numbers, or forward the traps coming in to UDP port 162.
- To forward incoming traps to another trap receiver, such as Microsoft SNMP Trap Service, set the Forwarding values as follows: `forward [IP address of other trap receiver]:[port number of other trap receiver] [SNMP version]`. For example: `forward 10.40.40.25:167 v1`. By default, incoming traps are not forwarded. For more information, see "Coexisting with Microsoft SNMP Trap Service" on page 527.
- Restart Trap Receiver after any change to the configuration file. From Control Panel, double-click **Administrative Tools** and then double-click **Services**. Right-click **NetIQ Trap Receiver** and select **Restart**.

13.24.4.5 Coexisting with Microsoft SNMP Trap Service

Two trap receivers cannot be in use on the same computer while using the same standard UDP port (162). If NetIQ SNMP Trap Receiver and another trap receiver such as Microsoft SNMP Trap Service are installed on the same computer and both are receiving traps, then configure Trap Receiver to use the standard UDP port and to forward incoming traps (UDP forwarding) to the other trap receiver. For more information, see "Understanding the Trap Receiver Configuration File" on page 526.

Then, configure the other trap receiver to use a different, non-standard, UDP port that is not in use by another application. The following are instructions for configuring Microsoft SNMP Trap Service.

To configure Microsoft SNMP Trap Service to use another port:

1. Navigate to `c:\Windows\system32\drivers\etc`.
2. Open the **services** file.
3. In the row for `snmptrap`, change the value for **udp** from 162 to another port number that is not in use by any other application. Use the same port number you set as the forwarding port in the Trap Receiver configuration file.
4. Save and close the **services** file.
5. Restart Windows SNMP Trap Service. In Control Panel, double-click **Administrative Tools** and then double-click **Services**. Right-click **SNMP Trap Service** and select **Restart**.

TIP: To see which ports are in use, run `netstat.exe` from a command prompt. Then select an available port as the port for the other trap receiver service.

13.25 SystemUptime

Use this Knowledge Script to monitor the number of hours that an Avaya Communication Manager has been operational since its last reboot. This script raises an event if the server reboots. In addition, this script generates a data stream for server uptime.

13.25.1 Resource Object

AvayaCM Server object

13.25.2 Default Schedule

By default, this script runs every 5 minutes.

13.25.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Job Failure Notification	
Event severity when job fails	Set the event severity level, from 1 to 40, to indicate the importance of the failure of the SystemUptime job. The default is 5.
Monitor Reboot Events	
Event Notification	
Raise event if server reboots?	Select **Yes** to raise an event if the Avaya Communication Manager server reboots. The default is Yes.
Event severity when server reboots	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the Avaya Communication Manager server reboots. The default is 5.
Monitor Uptime	
Data Collection	
Collect data for uptime?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the amount of time the Avaya Communication Manager server has been operational since its last reboot. The default is Yes.

13.26 TrunkGroupUsage

Use this Knowledge Script to monitor the status of a trunk group. This script raises an event if a monitored value exceeds the threshold you set. In addition, this script generates data streams for the following statistics:

- Total number of hours all trunks are busy with calls
- Percentage of time all trunks are simultaneously in use
- Calls in queue
- Calls not in queue
- Out-of-service trunks

13.26.1 Resource Object

AvayaCM Trunk Group object

13.26.2 Default Schedule

By default, this script runs every hour because the SNMP data it monitors is updated only once an hour. If you change the schedule to a shorter interval, you may receive SNMP request errors until the SNMP data is repopulated.

13.26.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Job Failure Notification	
Event severity when job fails	Set the event severity level, from 1 to 40, to indicate the importance of the failure of the TrunkGroupUsage job. The default is 5.
Monitor Total Hours Trunks Busy with Calls	
Event Notification	
Raise event if total hours trunks busy with calls exceeds threshold?	Select **Yes** to raise an event if the total number of hours that all trunks are busy with calls exceeds the threshold you set. The default is Yes.
Threshold - Maximum total hours trunks busy with calls	Specify the highest number of hours that all trunks can be busy with calls before an event is raised. The default is 1 hour.
Event severity when total hours trunks busy with calls exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the total number of hours that all trunks are busy with calls exceeds the threshold. The default is 15.
Data Collection	

Parameter	How to Set It
Collect data for total hours trunks busy with calls?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the total number of hours that all trunks were busy with calls during the monitoring period. The default is Yes.
Monitor Calls Queued	
Event Notification	
Raise event if number of calls queued exceeds threshold?	Select **Yes** to raise an event if the number of calls in queue exceeds the threshold you set. The default is Yes.
Threshold - Maximum calls queued	Specify the maximum number of calls that can be in queue before an event is raised. The default is 10 calls.
Event severity when number of calls queued exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of calls in queue exceeds the threshold. The default is 15.
Data Collection	
Collect data for calls queued?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the number of calls in queue during the monitoring period. The default is Yes.
Monitor Calls Not Queued	
Event Notification	
Raise event if number of calls not queued exceeds threshold?	Select **Yes** to raise an event if the number of calls not in queue exceeds the threshold you set. The default is Yes. Calls not in queue are calls that were offered to the trunk group when the queue was full.
Threshold - Maximum calls not queued	Specify the maximum number of calls that can be not queued before an event is raised. The default is 5 calls.
Event severity when number of calls not queued exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of calls not queued exceeds the threshold. The default is 15.
Data Collection	
Collect data for calls not queued?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the number of calls not queued during the monitoring period. The default is unselected.
Monitor Trunks Out of Service	
Event Notification	
Raise event if number of trunks out of service exceeds threshold?	Select **Yes** to raise an event if the number of out-of-service trunks exceeds the threshold you set. The default is Yes.
Threshold - Maximum trunks out of service	Specify the maximum number of trunks that can be out of service before an event is raised. The default is 1 trunk.
Event severity when number of trunks out of service exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of out-of-service trunks exceeds the threshold. The default is 15.
Data Collection	
Collect data for trunks out of service?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the number of trunks that were out of service during the monitoring period. The default is Yes.

Parameter	How to Set It
Monitor Percent Time Trunks in Use	
Event Notification	
Raise event if percent of time all trunks simultaneously in use exceeds threshold?	Select **Yes** to raise an event if the percentage of time that all trunks are simultaneously in use exceeds the threshold you set. The default is Yes.
Threshold - Maximum percent of time all trunks simultaneously in use	Specify the highest percentage of time that all trunks can be simultaneously in use before an event is raised. The default is 1%.
Event severity when percent of time all trunks simultaneously in use exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the percentage of time that all trunks are simultaneously in use exceeds the threshold. The default is 15.
Data Collection	
Collect data for percent of time all trunks simultaneously in use?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the percentage of time that all trunks were simultaneously in use during the monitoring period. The default is Yes.

13.27 Recommended Knowledge Script Group

The following Knowledge Scripts are members of the AvayaCM recommended Knowledge Script Group (KSG).

- CallActivity
- CPU_Usage
- ESS_Status
- H248GatewayStatus
- LSP_Status
- RegisteredResources
- SecurityViolations
- SystemUptime

The parameters of all scripts in the KSG are set to recommended values. To run all of the recommended scripts at one time, click the RECOMMENDED tab and run the AvayaCM group on a Communication Manager resource.

Run the KSG on only one cluster at a time. Running the KSG on multiple clusters all at once hinders the proxy agent's ability to spread out processing over time. You can monitor multiple clusters by running the KSG on the first cluster, and then repeating the process for each additional cluster.

The AvayaCM KSG provides a "best practices" usage of AppManager for monitoring your Communication Manager environment. You can use this KSG with AppManager monitoring policies. A monitoring policy, which enables you to efficiently and consistently monitor all the resources in your environment, uses a set of pre-configured Knowledge Scripts to automatically monitor resources as they appear in the TreeView. For more information, see "About Policy-Based Monitoring" in the AppManager Help.

A KSG is composed of a subset of a module's Knowledge Scripts. The script that belongs to a KSG is a different copy of the original script you access from the AvayaCM tab. If you modify a script that belongs to a KSG, the parameter settings of the original script in the AvayaCM tab are not affected.

When deployed as part of a KSG, a script's default script parameter settings may differ from when the script is deployed alone. The default settings of a script within a group depend on its monitoring purpose within the larger group, and on the intended monitoring scope of that group.

If you modify or remove a script associated with the AvayaCM KSG and want to restore it to its original form, you can reinstall the AppManager for Avaya Communication Manager module on the repository computer or check in the appropriate script from the `AppManager\qdb\kp\AvayaCM\RECOMMENDED_AvayaCM` directory.

14 BackupExec Knowledge Scripts

AppManager provides the following set of Knowledge Scripts for monitoring Backup Exec resources. From the Knowledge Script view of Control Center, you can access more information about any NetIQ-supported Knowledge Script by selecting it and clicking **Help**. In the Operator Console, click any Knowledge Script in the Knowledge Script pane and press **F1**.

Knowledge Script	What It Does
AbortedJobs	Monitors the number of aborted or cancelled Backup Exec jobs.
ActiveJobIDs	Monitors the number of jobs that were active when the script ran.
CompletedJobs	Monitors the number of jobs that were completed during the monitoring interval.
FailedJobs	Monitors the number of failed Backup Exec jobs.
IncompleteJobs	Monitors the number of Backup Exec jobs that have not completed.
LatestJob	Scans the Backup Exec log and returns the status of the last completed Backup Exec job.
Report_Availability	Generates a report about Backup Exec availability.
Report_IDsofActiveJobs	Generates a report about the number of active Backup Exec jobs.
Report_NumberofAbortedJobs	Generates a report about the number of aborted Backup Exec jobs.
Report_NumberofCompletedJobs	Generates a report about the number of completed Backup Exec jobs.
Report_NumberofFailedJobs	Generates a report about the number of failed Backup Exec jobs.
Report_NumberofIncompleteJobs	Generates a report about the number of incomplete Backup Exec jobs.
Report_StatusofTheLatestJob	Generates a report about the status of the most-recently-submitted backup job.
ResourceHigh	Monitors the CPU and memory usage of Backup Exec services.
ResubmitFailedJobs	Checks for backup jobs that failed and resubmits those jobs to the Backup Exec server.
ServiceDown	Monitors Backup Exec services to see if they are running.
SkippedFilesInJobs	Monitors the number of files that were skipped during backups that finished within the last monitoring interval.
SuccessfulJobs	Monitors the number of Backup Exec jobs that completed successfully.
TotalBytes	Monitors the total number of bytes backed up during the last monitoring interval.

14.1 About bemcmd.exe

Several Knowledge Scripts need the `bemcmd.exe` applet in order to retrieve information from the Backup Exec sever. This applet ships along with the Symantec Backup Exec software.

With Knowledge Scripts that use `bemcmd.exe`, you cannot configure an interval of less than 5 minutes. This prevents overloading of the Backup Exec server with `bemcmd` requests.

Knowledge Scripts that use `bemcmd.exe` cannot process a completed job history of more than about 350 entries. If they encounter more than about 350 completed job history entries, the following Knowledge Scripts will abort the job:

- CompletedJobs
- SuccessfulJobs
- SkippedFilesInJobs

If a job is aborted due to this limitation, you must delete older job history entries and then try to run the Knowledge Script again.

The following Knowledge Scripts require `bemcmd.exe` in order to run successfully:

- ActiveJobIDs
- CompletedJobs
- ResubmitFailedJobs
- SkippedFilesInJobs
- SuccessfulJobs

14.2 AbortedJobs

Use this Knowledge Script to monitor the number of aborted or cancelled Backup Exec jobs and return data about those jobs.

This script periodically scans the Windows Application Event Log for any entries that Backup Exec made regarding aborted or cancelled jobs. When this Knowledge Script starts, it uses the value specified for the **Start with events in past N hours** parameter to determine how to process entries already in the event log. While running at the interval specified on the Schedule tab, it scans the event log for any new entries created since the last time it checked.

If the number of cancelled jobs found in the event log exceeds the threshold you set during any monitoring interval, an event is raised.

14.2.1 Resource Object

Backup Exec

14.2.2 Default Schedule

The default interval for this script is Every 24 hours.

14.2.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Raise event if threshold exceeded?	Set to **y** to raise events. Default is y.
Collect data for number of aborted jobs?	Set to **y** to collect data for reports and graphs. When set to **y**, returns the number of cancelled jobs found. Default is n.
Start with events in past *N* hours	Set this parameter to determine which events are searched the first time the Knowledge Script is run. Subsequent searches begin where the last search finished. The following values are valid: • -1 – search all Application Event Log events that occur before and during the first monitoring interval. During subsequent monitoring intervals, only events that occur during the interval are searched. • 0 – search only for events that occur during the monitoring interval; previous events are not searched. • *N* – the number of hours to go back in the event log to scan for matching events. For example, enter 8 to scan the last 8 hours of the event log for matching entries. Default is 0.
Threshold – Maximum number of aborted jobs	Enter the maximum number of cancelled jobs allowed during any interval before an event is raised. Default is 10 cancelled jobs.
Event severity when threshold exceeded	Set the event severity level, from 1 to 40, to indicate the importance of the event. Default severity level is 5.

14.3 ActiveJobIDs

Use this Knowledge Script to check the number of jobs that are active when the script runs. It does not report all jobs that have been active since this script was last executed.

An "active" job is any job with a status of running, loading, or pending (queued). If the number of active jobs exceeds the maximum threshold or falls below the minimum threshold you set, an event is raised.

This Knowledge Script is useful for verifying that a specific job is still in process. You can also use it to retrieve the job ID of any currently active job.

NOTE: This script requires bemcmd.exe to run successfully. See "About bemcmd.exe" on page 534 for more information.

14.3.1 Resource Object

Backup Exec

14.3.2 Default Schedule

The default interval for this script is Every 24 hours. This Knowledge Script must be run at intervals of 5 minutes or more.

14.3.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Raise event if threshold exceeded or not met?	Set to **y** to raise events. Default is y.
Collect data for number of active jobs?	Set to **y** to collect data for reports and graphs. If set to **y**, returns the number of active jobs, and the job IDs of the active jobs. Default is n.
Threshold – Maximum number of active jobs	Specify a maximum number of active jobs. If the actual number of active jobs exceeds this threshold, an event is raised. Default is 20 active jobs.
Threshold – Minimum number of active jobs	Specify a minimum number of active jobs. If the actual number of active jobs falls below this threshold, an event is raised. Default is 5 active jobs.
Event severity when threshold exceeded or not met	Set the event severity level, from 1 to 40, to indicate the importance of the event. Default severity level is 12.

14.4 CompletedJobs

Use this Knowledge Script to monitor the number of jobs that were completed during the monitoring interval, regardless of their outcome. A completed job is any job with a status of Cancelled, Successful, or Failed.

If the number of completed jobs exceeds the maximum threshold or falls below the minimum threshold you set, an event is raised.

NOTE: This script requires bemcmd.exe to run successfully. See "About bemcmd.exe" on page 534 for more information.

14.4.1 Resource Object

Backup Exec

14.4.2 Default Schedule

The default interval for this script is Every 24 hours. This Knowledge Script must be run at intervals of 5 minutes or more.

14.4.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Raise event if threshold exceeded or not met?	Set to **y** to raise events. Default is y.
Collect data for number of completed jobs?	Set to **y** to collect data for reports and graphs. If set to **y**, returns the number of completed jobs, and the IDs of the completed jobs. Default is n.
Threshold – Maximum number of completed jobs	Specify a maximum number of completed jobs. If the number of completed jobs exceeds this threshold, an event is raised. Default is 20 completed jobs.
Threshold – Minimum number of completed jobs	Specify the minimum number of completed jobs. If the number of completed jobs falls below this threshold, an event is raised. Default is 5 completed jobs.
Event severity when threshold exceeded or not met	Set the event severity level, from 1 to 40, to indicate the importance of the event. Default severity level is 12.

14.5 FailedJobs

Use this Knowledge Script to monitor the number of failed Backup Exec jobs and return data about those jobs.

This Knowledge Script periodically scans the Windows Application Event Log for any entries that Backup Exec made regarding failed jobs. When this Knowledge Script starts, it uses the value specified for the **Start with events in past N hours** parameter to determine how to process entries already in the event log. While running at the interval specified on the Schedule tab, it scans the event log for any new entries created since the last time it checked.

If the number of failed jobs found in the event log exceeds the threshold you specify during any interval, an event is raised. This Knowledge Script returns the number of failed jobs, and the event detail message shows each job's name, start time, and end time.

14.5.1 Resource Object

Backup Exec

14.5.2 Default Schedule

The default interval for this script is Every 24 hours.

14.5.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Raise event if threshold exceeded?	Set to **y** to raise events. Default is y.
Collect data for number of failed jobs?	Set to **y** to collect data for reports and graphs. If set to **y**, returns the number of failed jobs found. Default is n.
Start with events in past *N* hours	Set this parameter to determine which events to search for the first time the Knowledge Script is run. Subsequent searches begin where the last search finished. The following values are valid: • -1 – search all Application Event Log events that occur before and during the first monitoring interval. During subsequent monitoring intervals, only events that occur during the interval are searched. • 0 – search only for events that occur during the monitoring interval; previous events are not searched. • *N* – the number of hours to go back in the event log to scan for matching events. For example, enter 8 to scan the last 8 hours of the event log for matching entries. Default is 0.
Threshold – Maximum number of failed jobs	Specify the maximum number of failed jobs. If the number of failed jobs exceeds this threshold, an event is raised. Default is 10 failed jobs.
Event severity when threshold exceeded	Set the event severity level, from 1 to 40, to indicate the importance of the event. Default severity level is 5.

14.6 IncompleteJobs

Use this Knowledge Script to monitor the number of Backup Exec jobs that have not completed and to return data about those jobs.

This script periodically scans the Backup Exec log for any entries that contain only a data header but no job information. An entry with only a data header indicates that Backup Exec has begun to track the job, but the job is not yet complete.

This Knowledge Script does not determine why the job is not complete. In most cases, however, it indicates that the job is pending (queued) or still running.

If the number of jobs that have not completed exceeds the threshold you set during any interval, an event is raised.

14.6.1 Resource Object

Backup Exec

14.6.2 Default Schedule

The default interval for this script is Every 24 hours.

14.6.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Raise event if threshold exceeded?	Set to **y** to raise events. Default is y.
Collect data for number of incomplete jobs?	Set to **y** to collect data for reports and graphs. If set to **y**, returns the number of jobs that have not completed. Default is n.
Threshold – Maximum number of incomplete jobs	Specify the maximum number of incomplete jobs. If the number of incomplete jobs exceeds this threshold, an event is raised. Default is 2 incomplete jobs.
Event severity when threshold exceeded	If events are enabled, set the event severity level, from 1 to 40, to indicate the importance of the event. Default severity level is 5.

14.7 LatestJob

Use this Knowledge Script to monitor the status of the last completed Backup Exec job and return data about that job.

This script periodically scans the Backup Exec log for the status of the last completed backup or restore job. An event is raised if the last job failed. You can set this Knowledge Script to raise an event if the latest job completed successfully.

This Knowledge Script can also monitor the size of the backup file and raise an event if the file exceeds the maximum threshold or falls below the minimum threshold you set. A file that is too large or too small can indicate a problem with the backup.

An event can be raised if the media label on the disk cartridge where the current backup was made is identical to the media label of the disk where the previous backup was made. If the two media labels are identical, it may indicate that the current backup overwrote a previous backup. This Knowledge Script can detect this condition, but only after the first script iteration is complete.

14.7.1 Resource Object

Backup Exec

14.7.2 Default Schedule

The default interval for this script is Every 24 hours.

14.7.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Raise event if last job ran successfully?	Set this parameter to **y** to raise an event when the last job ran successfully. Default is n. **NOTE:** This script always raises an event when the last job failed.
Collect data for status of last job?	Set to **y** to collect data for reports and graphs. If set to **y**, returns the number of jobs that have not completed. Default is n.
Threshold – Maximum size of backup file	Specify the maximum size of the backup file. If the file size exceeds this threshold, an event is raised. Default is 2000 MB.
Threshold – Minimum size of backup file	Specify the minimum size of the backup file. If the file size falls below this threshold, an event is raised. Default is 10 MB.

Description	How to Set It
Event severity level if...	Set the event severity level, from 1 to 40, to indicate the importance of: • **... last job failed**. Enter a value that indicates the latest job failed. Default is 5. • **... last job succeeded**. Enter a value that indicates the latest job completed successfully. Default is 25. • **... duplicate disk label found**. Enter a value to indicate that the media label of the current backup disk is the same as the media label of the previous backup disk. Default is 15. • **... file size warning**. Enter a value to indicate that the size of the backup file was larger or smaller than the thresholds you set. Default is 18.

14.8 Report_Availability

Use this Report Knowledge Script to generate a report about the availability of Backup Exec based on the up and down status of Backup Exec services.

This report uses data collected by the ServiceDown Knowledge Script.

14.8.1 Resource Objects

Report Agent > AM Repositories > *AppManager repository*.

14.8.2 Default Schedule

The default schedule is Run once.

14.8.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Data source	Use the following parameters to select the data for your report.
Select computer(s)	Click the **Browse [...]** button to start the data wizard. Use the data wizard to select the computers for your report.
Select time range	Click the **Browse [...]** button to open the time browser. Set a specific or sliding time range for data included in your report.
Select peak weekday(s)	Click the **Browse [...]** button to select the days of the week to include in your report.
Data settings	Use the following parameters to define the statistical calculation applied to data, and which data is displayed.
Hours or percentage on chart	Select whether to illustrate availability by hours or as a percentage.
Select sorting/display option	Select whether data is sorted, or the method of display: • **No sort**: Data is not sorted • **Sort**: Data is sorted by value (lowest to highest from front to back; highest to lowest from left to right) • **Top %**: Chart only the top *N* % of selected data (sorted by default) • **Top** *N*: Chart only the top *N* of selected data (sorted by default) • **Bottom %**: Chart only the bottom *N*% of data (sorted by default) • **Bottom** *N*: Chart only the bottom *N* of selected data (sorted by default)
Percentage/count for top/bottom	Enter a number for either the percent or count defined in the previous parameter (for example, Top 10%, or Top 10). Default is 25.
Truncate top/bottom?	If set to yes, the data table shows only the top or bottom *N* or % (for example, only the top 10%). Otherwise, the table shows all data. Default is no.

Description	How to Set It
Report settings	Use the following parameters to define the graphical presentation of data, the folder where the report is generated, and properties that identify the report.
Include parameter help card?	Set to yes to include a table in the report that lists parameter settings for the report script. Default is yes.
Include table?	Set to yes to include a table of data stream values in the report. Default is yes.
Include chart?	Set to yes to include a chart of data stream values in the report. The default is yes.
Select chart style	Click the **Browse [...]** button to open the Chart Settings dialog box. Define the graphic properties of the charts in your report. Default is pie chart style.
Select output folder	Click the **Browse [...]** button to set parameters for the output folder.
Add job ID to output folder name?	Set to yes to append the job ID to the name of the output folder. Adding the job ID to the output folder name is helpful to identify a specific instance of a report Knowledge Script with its corresponding report. Default is no.
Select properties	Click the **Browse [...]** button to open the Report Properties dialog box. Set the properties parameters as desired.
Add time stamp to title?	Set to yes to append a timestamp to the title of the report, making each title unique. The timestamp consists of the date and time the report was generated. Adding a timestamp lets you run consecutive iterations of the same report without overwriting previous output. Default is no.
Event notification	Use the following parameters to raise events associated with generating the report, and to set severity levels for those events.
Event for report success?	Set to yes to raise an event when the report is successfully generated. Default is yes.
Severity level for report success	Set the event severity level, from 1 to 40, to indicate the importance of the event. Default is 35.
Severity level for report with no data	Set the event severity level, from 1 to 40, to indicate the importance of the event. Default is 25.
Severity level for report failure.	Set the event severity level, from 1 to 40, to indicate the importance of the event. Default is 5.

14.9 Report_IDsofActiveJobs

Use this Report Knowledge Script to generate a report about the number of active Backup Exec jobs. This report allows you to make a statistical analysis of the data point values (for example, the average or maximum value over a period of time).

This report uses data collected by the ActiveJobIDs Knowledge Script.

14.9.1 Resource Object

Report Agent > AM Repositories > *AppManager repository*.

14.9.2 Default Schedule

The default schedule is Run once.

14.9.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Data source	Use the following parameters to select the data for your report.
Select computers	Click the **Browse [...]** button to start the data wizard. Use the data wizard to select the computers to be included in your report.
Select time range	Click the **Browse [...]** button to open the time browser. Set a specific or sliding time range for data included in your report.
Select peak weekday(s)	Click the **Browse [...]** button to select the days of the week to include in your report.
Statistics to show	Select a statistical method by which to display data in the report: • **Average**: Average value of data points for the aggregation interval (for example, the average value for 1 hour) • **Minimum**/**Average**/**Maximum**: Minimum, average, and maximum values of data points for the aggregation interval • **Minimum**: Minimum value of data points for the aggregation interval • **Maximum**: Maximum value of data points for the aggregation interval • **Range**: Range of values in the data stream (maximum - minimum = range) • **StandardDeviation**: Measure of how widely values are dispersed from the mean • **Sum**: Total value of data points for the aggregation interval • **Open**/**Close**: Last value for the aggregation interval • **Change**: Difference between the first and last values for the time range of the report (close - open = change) • **Count**: Number of data points for the time range of the report

Description	How to Set It
Select sorting/display option	Select whether data is sorted, or the method of display: • **No sort**: Data is not sorted • **Sort**: Data is sorted by value (lowest to highest from front to back; highest to lowest from left to right) • **Top %**: Chart only the top *N* % of selected data (sorted by default) • **Top N**: Chart only the top *N* of selected data (sorted by default) • **Bottom %**: Chart only the bottom *N* % of data (sorted by default) • **Bottom N**: Chart only the bottom *N* of selected data (sorted by default)
Percentage/count for top/bottom	Enter a number for either the percent or count defined in the previous parameter (for example, Top 10%, or Top 10). Default is 25.
Truncate top/bottom?	If set to yes, then the data table shows only the top or bottom *N* or % (for example, only the top 10%). Otherwise, the table shows all data. Default is no.
Show totals on the table?	If set to yes, additional calculations are made for each column of numbers in a table, and the following values are listed at the end of the table: • **Report Average**: Average of all values in a column • **Report Minimum**: Minimum value in a column • **Report Maximum**: Maximum value in a column • **Report Total**: Total of all values in a column Default is no.
Report settings	Use the following parameters to define the graphical presentation of data, the folder where the report is generated, and properties that identify the report.
Include parameter help card?	Set to **y** to include a table in the report that lists parameter settings for the report script. Default is y.
Include table?	Set to **y** to include a table of data stream values in the report. Default is y.
Include chart?	Set to **y** to include a chart of data stream values in the report. Default is y.
Select chart style	Click the **Browse [...]** button to open the Chart Settings dialog box. Define the graphic properties of the charts in your report.
Select output folder	Click the **Browse [...]** button to set parameters for the output folder.
Add job ID to output folder name?	Set to yes to append the job ID to the name of the output folder. This is helpful to correlate a specific instance of a Report Script and the corresponding report. Default is no.
Select properties	Click the **Browse [...]** button to open the Report Properties dialog box. Set the properties as desired.
Add time stamp to title	Set to **y** to append a timestamp to the title of the report. The timestamp consists of the date and time the report was generated. Adding a timestamp lets you run consecutive iterations of the same report without overwriting previous output. Default is n.

Description	How to Set It
Event notification	Use the following parameters to raise events associated with generating the report, and to set severity levels for those events.
Event for report success?	Set to **y** to raise an event when the report is successfully generated. Default is y.
Severity level for report success	Set the event severity level, from 1 to 40, to indicate the importance of the event. Default is 35.
Severity level for report with no data	Set the event severity level, from 1 to 40, to indicate the importance of the event. Default is 25.
Severity level for report failure.	Set the event severity level, from 1 to 40, to indicate the importance of the event. Default is 5.

14.10 Report_NumberofAbortedJobs

Use this Report Knowledge Script to generate a report about the number of aborted Backup Exec jobs. This report allows you to make a statistical analysis of the data point values (for example, the average or maximum value over a time period).

This report uses data collected by the AbortedJobs Knowledge Script.

14.10.1 Resource Object

Report Agent > AM Repositories > *AppManager repository*.

14.10.2 Default Schedule

The default schedule is Run once.

14.10.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Data source	Use the following parameters to select the data for your report.
Select computers	Click the **Browse [...]** button to start the data wizard. Use the data wizard to select the computers to be included in your report.
Select time range	Click the **Browse [...]** button to open the time browser. Set a specific or sliding time range for data included in your report.
Select peak weekday(s)	Click the **Browse [...]** button to select the days of the week to include in your report.
Statistics to show	Select a statistical method by which to display data in the report: • **Average**: Average value of data points for the aggregation interval (for example, the average value for 1 hour) • **Minimum**/**Average**/**Maximum**: Minimum, average, and maximum values of data points for the aggregation interval • **Minimum**: Minimum value of data points for the aggregation interval • **Maximum**: Maximum value of data points for the aggregation interval • **Range**: Range of values in the data stream (maximum - minimum = range) • **StandardDeviation**: Measure of how widely values are dispersed from the mean • **Sum**: Total value of data points for the aggregation interval • **Open**/**Close**: Last value for the aggregation interval • **Change**: Difference between the first and last values for the time range of the report (close - open = change) • **Count**: Number of data points for the time range of the report

Description	How to Set It
Select sorting/display option	Select whether data is sorted, or the method of display: • **No sort**: Data is not sorted • **Sort**: Data is sorted by value (lowest to highest from front to back; highest to lowest from left to right) • **Top %**: Chart only the top *N* % of selected data (sorted by default) • **Top N**: Chart only the top *N* of selected data (sorted by default) • **Bottom %**: Chart only the bottom *N* % of data (sorted by default) • **Bottom N**: Chart only the bottom *N* of selected data (sorted by default)
Percentage/count for top/bottom	Enter a number for either the percent or count defined in the previous parameter (for example, Top 10%, or Top 10). Default is 25.
Truncate top/bottom?	If set to yes, then the data table shows only the top or bottom *N* or % (for example, only the top 10%). Otherwise, the table shows all data. Default is no.
Show totals on the table?	If set to yes, additional calculations are made for each column of numbers in a table, and the following values are listed at the end of the table: • **Report Average**: Average of all values in a column • **Report Minimum**: Minimum value in a column • **Report Maximum**: Maximum value in a column • **Report Total**: Total of all values in a column Default is no.
Report settings	Use the following parameters to define the graphical presentation of data, the folder where the report is generated, and properties that identify the report.
Include parameter help card?	Set to **y** to include a table in the report that lists parameter settings for the report script. Default is y.
Include table?	Set to **y** to include a table of data stream values in the report. Default is y.
Include chart?	Set to **y** to include a chart of data stream values in the report. Default is y.
Select chart style	Click the **Browse [...]** button to open the Chart Settings dialog box. Define the graphic properties of the charts in your report.
Select output folder	Click the **Browse [...]** button to set parameters for the output folder.
Add job ID to output folder name?	Set to yes to append the job ID to the name of the output folder. This is helpful to correlate a specific instance of a Report Script and the corresponding report. Default is no.
Select properties	Click the **Browse [...]** button to open the Report Properties dialog box. Set the properties as desired.
Add time stamp to title	Set to **y** to append a timestamp to the title of the report. The timestamp consists of the date and time the report was generated. Adding a timestamp lets you run consecutive iterations of the same report without overwriting previous output. Default is n.

Description	How to Set It
Event notification	Use the following parameters to raise events associated with generating the report, and to set severity levels for those events.
Event for report success?	Set to **y** to raise an event when the report is successfully generated. Default is y.
Severity level for report success	Set the event severity level, from 1 to 40, to indicate the importance of the event. Default is 35.
Severity level for report with no data	Set the event severity level, from 1 to 40, to indicate the importance of the event. Default is 25.
Severity level for report failure.	Set the event severity level, from 1 to 40, to indicate the importance of the event. Default is 5.

14.11 Report_NumberofCompletedJobs

Use this Report Knowledge Script to generate a report about the number of completed Backup Exec jobs. This report allows you to make a statistical analysis of the data point values (for example, the average or maximum value over a period of time).

This report uses data collected by the CompletedJobs Knowledge Script.

14.11.1 Resource Object

Report Agent > AM Repositories > *AppManager repository*.

14.11.2 Default Schedule

The default schedule is Run once.

14.11.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Data source	Use the following parameters to select the data for your report.
Select computers	Click the **Browse [...]** button to start the data wizard. Use the data wizard to select the computers for your report.
Select time range	Click the **Browse [...]** button to open the time browser. Set a specific or sliding time range for data included in your report.
Select peak weekday(s)	Click the **Browse [...]** button to select the days of the week to include in your report.
Statistics to show	Select a statistical method by which to display data in the report: • **Average**: Average value of data points for the aggregation interval (for example, the average value for 1 hour) • **Minimum**/**Average**/**Maximum**: Minimum, average, and maximum values of data points for the aggregation interval • **Minimum**: Minimum value of data points for the aggregation interval • **Maximum**: Maximum value of data points for the aggregation interval • **Range**: Range of values in the data stream (maximum - minimum = range) • **StandardDeviation**: Measure of how widely values are dispersed from the mean • **Sum**: Total value of data points for the aggregation interval • **Open**/**Close**: Last value for the aggregation interval • **Change**: Difference between the first and last values for the time range of the report (close - open = change) • **Count**: Number of data points for the time range of the report

Description	How to Set It
Select sorting/display option	Select whether data is sorted, or the method of display: • **No sort**: Data is not sorted • **Sort**: Data is sorted by value (lowest to highest from front to back; highest to lowest from left to right) • **Top %**: Chart only the top *N* % of selected data (sorted by default) • **Top N**: Chart only the top *N* of selected data (sorted by default) • **Bottom %**: Chart only the bottom *N* % of data (sorted by default) • **Bottom N**: Chart only the bottom *N* of selected data (sorted by default)
Percentage/count for top/bottom	Enter a number for either the percent or count defined in the previous parameter (for example, Top 10%, or Top 10). Default is 25.
Truncate top/bottom?	If set to yes, then the data table shows only the top or bottom *N* or % (for example, only the top 10%). Otherwise, the table shows all data. Default is no.
Show totals on the table?	If set to yes, additional calculations are made for each column of numbers in a table, and the following values are listed at the end of the table: • **Report Average**: Average of all values in a column • **Report Minimum**: Minimum value in a column • **Report Maximum**: Maximum value in a column • **Report Total**: Total of all values in a column Default is no.
Report settings	Use the following parameters to define the graphical presentation of data, the folder where the report is generated, and properties that identify the report.
Include parameter help card?	Set to **y** to include a table in the report that lists parameter settings for the report script. Default is y.
Include table?	Set to **y** to include a table of data stream values in the report. Default is y.
Include chart?	Set to **y** to include a chart of data stream values in the report. Default is y.
Select chart style	Click the **Browse [...]** button to open the Chart Settings dialog box. Define the graphic properties of the charts in your report.
Select output folder	Click the **Browse [...]** button to set parameters for the output folder.
Add job ID to output folder name?	Set to yes to append the job ID to the name of the output folder. This is helpful to correlate a specific instance of a Report Script and the corresponding report. Default is no.
Select properties	Click the **Browse [...]** button to open the Report Properties dialog box. Set the properties as desired.
Add time stamp to title	Set to **y** to append a timestamp to the title of the report. The timestamp consists of the date and time the report was generated. Adding a timestamp lets you run consecutive iterations of the same report without overwriting previous output. Default is n.

Description	How to Set It
Event notification	Use the following parameters to raise events associated with generating the report, and to set severity levels for those events.
Event for report success?	Set to **y** to raise an event when the report is successfully generated. Default is y.
Severity level for report success	Set the event severity level, from 1 to 40, to indicate the importance of the event. Default is 35.
Severity level for report with no data	Set the event severity level, from 1 to 40, to indicate the importance of the event. Default is 25.
Severity level for report failure.	Set the event severity level, from 1 to 40, to indicate the importance of the event. Default is 5.

14.12 Report_NumberofFailedJobs

Use this Report Knowledge Script to generate a report about the number of failed Backup Exec jobs. This report allows you to make a statistical analysis of the data point values (for example, the average or maximum value over a period of time).

This report uses data collected by the FailedJobs Knowledge Script.

14.12.1 Resource Object

Report Agent > AM Repositories > *AppManager repository*.

14.12.2 Default Schedule

The default schedule is Run once.

14.12.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Data source	Use the following parameters to select the data for your report.
Select computers	Click the **Browse [...]** button to start the data wizard. Use the data wizard to select the computers to be included in your report.
Select time range	Click the **Browse [...]** button to open the time browser. Set a specific or sliding time range for data included in your report.
Select peak weekday(s)	Click the **Browse [...]** button to select the days of the week to include in your report.
Statistics to show	Select a statistical method by which to display data in the report: • **Average**: Average value of data points for the aggregation interval (for example, the average value for 1 hour) • **Minimum**/**Average**/**Maximum**: Minimum, average, and maximum values of data points for the aggregation interval • **Minimum**: Minimum value of data points for the aggregation interval • **Maximum**: Maximum value of data points for the aggregation interval • **Range**: Range of values in the data stream (maximum - minimum = range) • **StandardDeviation**: Measure of how widely values are dispersed from the mean • **Sum**: Total value of data points for the aggregation interval • **Open**/**Close**: Last value for the aggregation interval • **Change**: Difference between the first and last values for the time range of the report (close - open = change) • **Count**: Number of data points for the time range of the report

Description	How to Set It
Select sorting/display option	Select whether data is sorted, or the method of display: • **No sort**: Data is not sorted • **Sort**: Data is sorted by value (lowest to highest from front to back; highest to lowest from left to right) • **Top %**: Chart only the top *N* % of selected data (sorted by default) • **Top N**: Chart only the top *N* of selected data (sorted by default) • **Bottom %**: Chart only the bottom *N* % of data (sorted by default) • **Bottom N**: Chart only the bottom *N* of selected data (sorted by default)
Percentage/count for top/bottom	Enter a number for either the percent or count defined in the previous parameter (for example, Top 10%, or Top 10). Default is 25.
Truncate top/bottom?	If set to yes, then the data table shows only the top or bottom *N* or % (for example, only the top 10%). Otherwise, the table shows all data. Default is no.
Show totals on the table?	If set to yes, additional calculations are made for each column of numbers in a table, and the following values are listed at the end of the table: • **Report Average**: Average of all values in a column • **Report Minimum**: Minimum value in a column • **Report Maximum**: Maximum value in a column • **Report Total**: Total of all values in a column Default is no.
Report settings	Use the following parameters to define the graphical presentation of data, the folder where the report is generated, and properties that identify the report.
Include parameter help card?	Set to **y** to include a table in the report that lists parameter settings for the report script. Default is y.
Include table?	Set to **y** to include a table of data stream values in the report. Default is y.
Include chart?	Set to **y** to include a chart of data stream values in the report. Default is y.
Select chart style	Click the **Browse [...]** button to open the Chart Settings dialog box. Define the graphic properties of the charts in your report.
Select output folder	Click the **Browse [...]** button to set parameters for the output folder.
Add job ID to output folder name?	Set to yes to append the job ID to the name of the output folder. This is helpful to correlate a specific instance of a Report Script and the corresponding report. Default is no.
Select properties	Click the **Browse [...]** button to open the Report Properties dialog box. Set the properties as desired.
Add time stamp to title	Set to **y** to append a timestamp to the title of the report. The timestamp consists of the date and time the report was generated. Adding a timestamp lets you run consecutive iterations of the same report without overwriting previous output. Default is n.

Description	How to Set It
Event notification	Use the following parameters to raise events associated with generating the report, and to set severity levels for those events.
Event for report success?	Set to **y** to raise an event when the report is successfully generated. Default is y.
Severity level for report success	Set the event severity level, from 1 to 40, to indicate the importance of the event. Default is 35.
Severity level for report with no data	Set the event severity level, from 1 to 40, to indicate the importance of the event. Default is 25.
Severity level for report failure.	Set the event severity level, from 1 to 40, to indicate the importance of the event. Default is 5.

14.13 Report_NumberofIncompleteJobs

Use this Report Knowledge Script to generate a report about the number of incomplete Backup Exec jobs. This report allows you to make a statistical analysis of the data point values (for example, the average or maximum value over a period of time).

This report uses data collected by the IncompleteJobs Knowledge Script.

14.13.1 Resource Object

Report Agent > AM Repositories > *AppManager repository*.

14.13.2 Default Schedule

The default schedule is Run once.

14.13.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Data source	Use the following parameters to select the data for your report.
Select computers	Click the **Browse [...]** button to start the data wizard. Use the data wizard to select the computers to be included in your report.
Select time range	Click the **Browse [...]** button to open the time browser. Set a specific or sliding time range for data included in your report.
Select peak weekday(s)	Click the **Browse [...]** button to select the days of the week to include in your report.
Statistics to show	Select a statistical method by which to display data in the report: • **Average**: Average value of data points for the aggregation interval (for example, the average value for 1 hour) • **Minimum**/**Average**/**Maximum**: Minimum, average, and maximum values of data points for the aggregation interval • **Minimum**: Minimum value of data points for the aggregation interval • **Maximum**: Maximum value of data points for the aggregation interval • **Range**: Range of values in the data stream (maximum - minimum = range) • **StandardDeviation**: Measure of how widely values are dispersed from the mean • **Sum**: Total value of data points for the aggregation interval • **Open**/**Close**: Last value for the aggregation interval • **Change**: Difference between the first and last values for the time range of the report (close - open = change) • **Count**: Number of data points for the time range of the report

Description	How to Set It
Select sorting/display option	Select whether data is sorted, or the method of display: • **No sort**: Data is not sorted • **Sort**: Data is sorted by value (lowest to highest from front to back; highest to lowest from left to right) • **Top %**: Chart only the top *N* % of selected data (sorted by default) • **Top N**: Chart only the top *N* of selected data (sorted by default) • **Bottom %**: Chart only the bottom *N* % of data (sorted by default) • **Bottom N**: Chart only the bottom *N* of selected data (sorted by default)
Percentage/count for top/bottom	Enter a number for either the percent or count defined in the previous parameter (for example, Top 10%, or Top 10). Default is 25.
Truncate top/bottom?	If set to yes, then the data table shows only the top or bottom *N* or % (for example, only the top 10%). Otherwise, the table shows all data. Default is no.
Show totals on the table?	If set to yes, additional calculations are made for each column of numbers in a table, and the following values are listed at the end of the table: • **Report Average**: Average of all values in a column • **Report Minimum**: Minimum value in a column • **Report Maximum**: Maximum value in a column • **Report Total**: Total of all values in a column Default is no.
Report settings	Use the following parameters to define the graphical presentation of data, the folder where the report is generated, and properties that identify the report.
Include parameter help card?	Set to **y** to include a table in the report that lists parameter settings for the report script. Default is y.
Include table?	Set to **y** to include a table of data stream values in the report. Default is y.
Include chart?	Set to **y** to include a chart of data stream values in the report. Default is y.
Select chart style	Click the **Browse [...]** button to open the Chart Settings dialog box. Define the graphic properties of the charts in your report.
Select output folder	Click the **Browse [...]** button to set parameters for the output folder.
Add job ID to output folder name?	Set to yes to append the job ID to the name of the output folder. This is helpful to correlate a specific instance of a Report Script and the corresponding report. Default is no.
Select properties	Click the **Browse [...]** button to open the Report Properties dialog box. Set the properties as desired.
Add time stamp to title	Set to **y** to append a timestamp to the title of the report. The timestamp consists of the date and time the report was generated. Adding a timestamp lets you run consecutive iterations of the same report without overwriting previous output. Default is n.

Description	How to Set It
Event notification	Use the following parameters to raise events associated with generating the report, and to set severity levels for those events.
Event for report success?	Set to **y** to raise an event when the report is successfully generated. Default is y.
Severity level for report success	Set the event severity level, from 1 to 40, to indicate the importance of the event. Default is 35.
Severity level for report with no data	Set the event severity level, from 1 to 40, to indicate the importance of the event. Default is 25.
Severity level for report failure.	Set the event severity level, from 1 to 40, to indicate the importance of the event. Default is 5.

14.14 Report_StatusofTheLatestJob

Use this Report Knowledge Script to generate a report about the status of the most recently submitted Backup Exec job. This report lets you make a statistical analysis of the data point values (for example, the average or maximum value over a time period).

This report uses data collected by the LatestJob Knowledge Script.

14.14.1 Resource Object

Report Agent > AM Repositories > *AppManager repository*.

14.14.2 Default Schedule

The default schedule is Run once.

14.14.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Data source	Use the following parameters to select the data for your report.
Select computers	Click the **Browse [...]** button to start the data wizard. Use the data wizard to select the computers to be included your report.
Select time range	Click the **Browse [...]** button to open the time browser. Set a specific or sliding time range for data included in your report.
Select peak weekday(s)	Click the **Browse [...]** button to select the days of the week to include in your report.
Statistics to show	Select a statistical method by which to display data in the report: • **Average**: Average value of data points for the aggregation interval (for example, the average value for 1 hour) • **Minimum**/**Average**/**Maximum**: Minimum, average, and maximum values of data points for the aggregation interval • **Minimum**: Minimum value of data points for the aggregation interval • **Maximum**: Maximum value of data points for the aggregation interval • **Range**: Range of values in the data stream (maximum - minimum = range) • **StandardDeviation**: Measure of how widely values are dispersed from the mean • **Sum**: Total value of data points for the aggregation interval • **Open**/**Close**: Last value for the aggregation interval • **Change**: Difference between the first and last values for the time range of the report (close - open = change) • **Count**: Number of data points for the time range of the report

Description	How to Set It
Select sorting/display option	Select whether data is sorted, or the method of display: • **No sort**: Data is not sorted • **Sort**: Data is sorted by value (lowest to highest from front to back; highest to lowest from left to right) • **Top %**: Chart only the top *N* % of selected data (sorted by default) • **Top N**: Chart only the top *N* of selected data (sorted by default) • **Bottom %**: Chart only the bottom *N* % of data (sorted by default) • **Bottom N**: Chart only the bottom *N* of selected data (sorted by default)
Percentage/count for top/bottom	Enter a number for either the percent or count defined in the previous parameter (for example, Top 10%, or Top 10). Default is 25.
Truncate top/bottom?	If set to yes, then the data table shows only the top or bottom *N* or % (for example, only the top 10%). Otherwise, the table shows all data. Default is no.
Show totals on the table?	If set to yes, additional calculations are made for each column of numbers in a table, and the following values are listed at the end of the table: • **Report Average**: Average of all values in a column • **Report Minimum**: Minimum value in a column • **Report Maximum**: Maximum value in a column • **Report Total**: Total of all values in a column Default is no.
Report settings	Use the following parameters to define the graphical presentation of data, the folder where the report is generated, and properties that identify the report.
Include parameter help card?	Set to **y** to include a table in the report that lists parameter settings for the report script. Default is y.
Include table?	Set to **y** to include a table of data stream values in the report. Default is y.
Include chart?	Set to **y** to include a chart of data stream values in the report. Default is y.
Select chart style	Click the **Browse [...]** button to open the Chart Settings dialog box. Define the graphical properties of the charts in your report.
Select output folder	Click the **Browse [...]** button to set parameters for the output folder.
Add job ID to output folder name?	Set to yes to append the job ID to the name of the output folder. This is helpful to correlate a specific instance of a Report Script and the corresponding report. Default is no.
Select properties	Click the **Browse [...]** button to open the Report Properties dialog box. Set the properties as desired.
Add time stamp to title	Set to **y** to append a timestamp to the title of the report. The timestamp consists of the date and time the report was generated. Adding a timestamp lets you run consecutive iterations of the same report without overwriting previous output. Default is n.

Description	How to Set It
Event notification	Use the following parameters to raise events associated with generating the report, and to set severity levels for those events.
Event for report success?	Set to **y** to raise an event when the report is successfully generated. Default is y.
Severity level for report success	Set the event severity level, from 1 to 40, to indicate the importance of the event. Default is 35.
Severity level for report with no data	Set the event severity level, from 1 to 40, to indicate the importance of the event. Default is 25.
Severity level for report failure.	Set the event severity level, from 1 to 40, to indicate the importance of the event. Default is 5.

14.15 ResourceHigh

Use this Knowledge Script to monitor the CPU and memory usage of the Backup Exec services that were found during discovery. If the CPU or memory utilization associated with a monitored service exceeds one of the thresholds you set, an event is raised.

14.15.1 Resource Object

Backup Exec

14.15.2 Default Schedule

The default interval for this script is Every 24 hours.

14.15.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Raise event if threshold exceeded?	Set to **y** to raise events. Default is y.
Collect data for CPU and memory utilization?	Set to **y** to collect data for reports and graphs. If set to y, returns the CPU and memory utilization for each monitored service. Default is n.
Threshold – Maximum CPU utilization	Enter the maximum amount of CPU resources consumed by any single Backup Exec service. If CPU utilization exceeds this threshold, an event is raised. Default is 60%
Threshold – Maximum memory utilization	Enter the maximum amount of memory consumed by any single Backup Exec service. If memory utilization exceeds this threshold, an event is raised. Default is 6 MB.
Event severity when threshold exceeded	Set the event severity level, from 1 to 40, to indicate the importance of the event. Default severity level is 8.

14.16 ResubmitFailedJobs

Use this Knowledge Script to check for backup jobs that failed. If it finds any failed jobs, this Knowledge Script resubmits those jobs to the Backup Exec server.

NOTE: To check for–but not resubmit–failed backup jobs, use the FailedJobs Knowledge Script.

With releases of Backup Exec prior to 9.0, resubmitted jobs are restarted with a new job ID. For Backup Exec version 9.0 and later, the same job ID is re-used when the job is re-started.

You can set a threshold for the maximum number of resubmitted jobs during any monitoring interval. If the number of resubmitted jobs exceeds the threshold you set, an event is raised. The Knowledge Script still resubmits all failed jobs, even if an event is raised.

NOTE: This script requires bemcmd.exe to run successfully. See "About bemcmd.exe" on page 534 for more information.

14.16.1 Resource Object

Backup Exec

14.16.2 Default Schedule

The default interval for this script is Every 24 hours. This Knowledge Script must be run at intervals of 5 minutes or more.

14.16.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Raise event if jobs resubmitted or if threshold exceeded?	Set to **y** to raise events. Default is y.
Collect data for resubmitted jobs?	Set to **y** to collect data for reports and graphs. If set to y, returns the number of backup jobs that were resubmitted during the monitoring interval. Default is n.
Resubmitted jobs threshold	Specify the maximum number of resubmitted backup jobs. If the number of resubmitted backup jobs exceeds this threshold, an event is raised. Default is 10 resubmitted jobs.
Event severity when any job resubmitted	Set the event severity level, from 1 to 40, to indicate the importance of the event when any failed backup jobs are resubmitted. Default severity level is 12.
Event severity when threshold exceeded	Set the event severity level, from 1 to 40, to indicate the importance of the threshold-crossing event. Default severity level is 5.

14.17 ServiceDown

Use this Knowledge Script to monitor the availability of Backup Exec services that were found during discovery. You can set this script to automatically restart a service that is not running.

By default, an event is raised if any of the Backup Exec services are down.

14.17.1 Resource Object

Backup Exec

14.17.2 Default Schedule

The default interval for this script is Every 24 hours.

14.17.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Collect data for status of services?	Set to **y** to collect data for reports and graphs. If set to y, returns the following values: • 100 (service is up) • 0 (service is down) Default is n.
Restart service if down?	Set to **y** to automatically restart any service that is down. Default is y.
Event severity when...	Set the event severity level, from 1 to 40, to indicate the importance when: • **... attempt to restart fails**. Specify a value that indicates the service is down and AppManager cannot restart it. Default is 5. • **... attempt to restart succeeds**. Specify a value that indicates the service was down and AppManager successfully restarted it. Default is 25. • **... restart parameter is disabled**. Specify a value to indicate the service is down and the "Restart service if down?" parameter is set to n. Default is 18.

14.18 SkippedFilesInJobs

Use this Knowledge Script to monitor the number of files that were skipped during backup jobs that finished within the last monitoring interval. You can choose to monitor only successful jobs, only failed jobs, or both. In addition, you can filter by specific job IDs. If the total number of files that were skipped across all monitored jobs exceeds the threshold you set, an event is raised.

- First, this Knowledge Script determines the number of Backup Exec jobs that have completed between the current and last Knowledge Script iteration.
- Then it checks for either successful or failed jobs, depending on how you set the "**Monitor**..." parameters.

  If you enter job IDs for the **Filter by specific job IDs** parameter, this Knowledge Script filters the list of completed jobs it found and only considers the job IDs you specified.
- Finally, it looks for skipped files only within the types of jobs (successful or failed) you selected for monitoring.

If you enter an invalid job ID for the **Filter by specific job IDs** parameter, an error event states which job ID was found to be invalid on the first script iteration; however, the script continues to process the other job IDs that were supplied. Filtering by job ID is only supported on Backup Exec 9.x and later.

You must select **y** for either the **Monitor successful jobs** or the **Monitor failed jobs** parameter.

NOTE: This script requires bemcmd.exe to run successfully. See "About bemcmd.exe" on page 534 for more information.

14.18.1 Resource Object

Backup Exec

14.18.2 Default Schedule

The default interval for this script is Every 24 hours. This Knowledge Script must be run at intervals of 5 minutes or more.

14.18.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Raise event if threshold exceeded?	Set to **y** to raise events. Default is y.
Collect data for number of skipped files?	Set to **y** to collect data for reports and graphs. If set to **y**, returns the number of files skipped during the monitoring interval. Default is n.

Description	How to Set It
Filter: Backup Exec job IDs to include (comma-separated, no spaces)	To monitor only specific jobs, type the job IDs. Separate each job ID with commas, and do not use spaces. For example, enter job IDs in the following format: `{63D3C37C-9524-4D25-ABF8-2E0A42E33A6C}, {43D3B57G-9524-4D25-YGH8-2E0A42E33N6H}` **NOTE:** : This parameter is only supported on Backup Exec 9.x.
Monitor successful jobs?	Enter **y** to monitor only successful jobs. Default is y.
Monitor failed jobs?	Enter **y** to monitor only failed jobs. Default is n.
Threshold – Maximum number of files skipped	Specify the maximum number of files that can be skipped. If the number of files skipped exceeds this threshold, an event is raised. Default is 10 skipped files.
Event severity when threshold exceeded	Set the event severity level, from 1 to 40, to indicate the importance of the event. Default severity level is 5.

14.19 SuccessfulJobs

Use this Knowledge Script to monitor the number of successful Backup Exec jobs that were completed during the monitoring interval and return data about those jobs. A successful job is any job with a status of `Successful`.

If the number of successful jobs falls below the minimum threshold you set, an event is raised.

NOTE: This script requires bemcmd.exe to run successfully. See "About bemcmd.exe" on page 534 for more information.

14.19.1 Resource Object

Backup Exec

14.19.2 Default Schedule

The default interval for this script is Every 24 hours. This Knowledge Script must be run at intervals of 5 minutes or more.

14.19.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Raise event if threshold not met?	Set to **y** to raise events. Default is y.
Collect data for number of successful jobs?	Set to **y** to collect data for reports and graphs. If set to **y**, returns the number of successful jobs, and the IDs of the successful jobs. Default is n.
Threshold – Minimum number of successful jobs	Specify the minimum number of successful jobs. If the number of successful jobs falls below this threshold, an event is raised. Default is 10 successful jobs.
Event severity when threshold not met	Set the event severity level, from 1 to 40, to indicate the importance of the event. Default severity level is 5.

14.20 TotalBytes

Use this Knowledge Script to monitor the total number of bytes of data that were backed up during the last monitoring interval. If the number of bytes exceeds a threshold that you set, an event is raised.

14.20.1 Resource Object

Backup Exec

14.20.2 Default Schedule

The default interval for this script is Every 24 hours.

14.20.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Raise event if threshold exceeded?	Set to **y** to raise events. Default is y.
Collect data for number of bytes backed up?	Set to **y** to collect data for reports and graphs. If set to y, returns the number of bytes backed up since the last time the script ran. Default is n.
Threshold – Maximum number of bytes backed up	Specify the maximum number of bytes. If the number of bytes backed up exceeds this threshold, an event is raised. Default is 300 MB.
Event severity when threshold exceeded	Set the event severity level, from 1 to 40, to indicate the importance of the event. Default severity level is 8.

15 BES Knowledge Scripts

AppManager provides the following Knowledge Scripts for monitoring BlackBerry Enterprise Server resources.

From the Knowledge Script view of Control Center, you can access more information about any Knowledge Script by selecting it and clicking **Help**. In the Operator Console, select any Knowledge Script in the Knowledge Script pane and press **F1**.

Knowledge Script	What It Does
BlackberryAgent	Monitors the Blackberry agent log files for hung threads and the server being in STANDBY mode.
DebugLogSearch	Uses regular expressions to search for specified strings in log files.
DebugLogSize	Calculates the total debug log size, and purges log files if they exceed a size or age threshold.
HungThreads	Monitors the BlackBerry Enterprise Server service for hung threads.
InactiveUsers	Monitors the inactive users on a BlackBerry Enterprise Server.
MDSConnections	Monitors usage statistics for device and push connections.
MDSFailures	Monitors failure statistics for MDS connections.
MessageSize	Monitors the average size of messages forwarded and of messages to which replies with text were sent for a user on a BlackBerry Enterprise Server.
OrphanedUsers	Collects information on mismatched users from BlackBerry and Exchange Servers.
Report_EndToEndResponseTime	Generates a report about e-mail round-trip response time.
Report_LastUserCount	Generates a report about the last recorded user count and the percentage of licenses in use for a BlackBerry Enterprise Server.
Report_ServerMessageSummary	Generates a report about message activity on a BlackBerry Enterprise Server, including messages sent, received, filtered, and queued during the monitoring interval.
Report_SRPConnectivity	Generates a report about the percentage of uptime for the connection to the wireless network.
Report_UserMessageSummary	Generates a report about message activity per user on a BlackBerry Enterprise Server, including messages sent, received, filtered, and queued during the monitoring interval.
ResponseTime	Sends a message to a handheld device from the BlackBerry-enabled Exchange mailbox, checks for a reply, and determines end-to-end response time.

Knowledge Script	What It Does
ServerActivity	Monitors the number of messages that were forwarded, received, pending, expired, non-deliverable, and filtered by the server, plus the total number of messages processed by the server during a monitoring interval.
ServiceHealth	Monitors BlackBerry Enterprise Server service health, the amount of memory used, and the percentage of CPU time used by BlackBerry server processes.
SRPConnectionStatus	Monitors the status of the Server Routing Protocol (SRP) connection between the BlackBerry Enterprise Server and the Research in Motion (RIM) wireless infrastructure.
SRPTest	Performs a test of the SRP connection to make sure the wireless network can be reached.
UserActivity	Monitors the number of messages that were forwarded, received, pending, expired, non-deliverable, and filtered per user, plus the total number of messages processed by the server during the monitoring interval.
UserCount	Monitors the number of users on a BlackBerry Enterprise Server and the percentage of licenses used.
UsersWithPendingMessages	Monitors the percentage of users on a BlackBerry Enterprise Server who have messages pending for their handheld devices.

NOTE: The following Knowledge Scripts are not supported in BES 10 and later versions:

- BES_BlackBerryAgent
- BES_InactiveUsers
- BES_MessageSize
- BES_ResponseTime
- BES_ServerActivity
- BES_UserActivity
- BES_UsersWithPendingMessages

15.1 BlackberryAgent

Use this Knowledge Script to monitor a Blackberry agent for hung threads. Hung threads decrease the number of requests that can be concurrently processed by the service. Any thread that starts and then does not finish is considered hung.

This script raises an event only when both the number of hung threads and the wait count (in cycles) exceed the specified thresholds. You also have the option to restart the hung service automatically. If you choose to collect data, this script returns data about the number of hung threads, the thread IDs, and the wait count.

The wait count value that you set in the *Wait count – Cycles to wait before restarting service* parameter refers to the number of cycles that a thread has been blocked. If you enable data collection, this script returns the average wait count for the server. Use this statistic as guidance when you set a wait count.

To find hung threads, this script searches for several event IDs in the Blackberry agent event logs. These IDs are defined in the following table. You can also configure this script to look for additional event IDs. For more information, see "Monitoring Additional Event IDs" on page 584.

Event ID	Explanation
10019 – All worker threads seem to be blocked	All worker threads are unresponsive and cannot be allocated for work.
10165 – Thread: main timer thread appears to be blocked	RIM provides little information about this event or what it signifies. The event text mentions a "Queuing alarm" from BlackBerry Messaging.
20266 – At least one worker thread seems to be blocked (*N*)	One of the worker threads is blocked and unable to process mail. The parameter in parentheses indicates a wait count. The value of this parameter indicates how long the thread has been unresponsive: • 1 = 10 minutes • 2 = 20 minutes • 3 = 30 minutes **NOTE:** The BlackBerry Enterprise Server should automatically free hung threads and resume mail processing unless the Exchange Server is down.
20315 – Thread: *** No Response *** Thread Id=0xFC, Handle=0x238, WaitCount=7, SCS thread not responding, SCS - duplicate PIN check	An unresponsive worker thread has been found. Until it becomes unblocked, the thread cannot complete its work. The WaitCount indicates how long the thread has been in this state. In situations where the WaitCount value exceeds 10, the thread is unlikely to recover on its own.
30000 – Hung threads detected	An event with the 30000 ID contains the words "hung threads detected".
30038 – {0xD3} Thread: *** No Response ***	An unresponsive worker thread has been located. Until it becomes unblocked, the thread cannot complete its work. The condition will most likely be resolved without the need to restart the BlackBerry Enterprise Server.
50020 – {0xC3} Some worker threads have been blocked for 6 health checks	Worker threads that have been unresponsive for six health checks (60 minutes) have been found.
50023 – All worker threads of one of the pools seem to be blocked	All the threads assigned to a particular Exchange server are not responding. This could indicate a communication issue with that Exchange server, or it could indicate more widespread issues.

NOTE: This script currently is not supported for use with BES 10 and later.

15.1.1 Resource Object

Blackberry agent

15.1.2 Default Schedule

The default interval is **Every 10 minutes**.

15.1.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Job Failure Notification	
Event severity when job fails	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the BlackberryAgent job fails. The default is 5.
Restart BES services if hung threads detected?	Select **Yes** to have this script automatically restart services that have hung threads. Any service that has hung threads that have not become unblocked after the wait count has expired (see the *Wait count* parameter) will then be restarted. The default is unselected. When you enable this parameter, a service may be restarted automatically. However, the blocked thread must also meet one of the following conditions: • One (or both) of the following events is found in the event log: – 10019: All worker threads seem to be blocked – 50023: All worker threads of one of the pools seem to be blocked • The wait count you set using the *Wait count – Cycles to wait before restarting service* parameter has been exceeded by one of the hung threads that was found. • The value you set for the *Hung threads – Maximum number before restarting service* parameter has been exceeded by the number of hung threads found in the server event log.
Wait count – Cycles to wait before restarting service	Set a wait count for each hung thread. This script waits the specified number of cycles to detect whether hung threads become unblocked. The default is 3 cycles. **NOTE:** You should plan to run this script for a few days and collect data for average wait count on the server to use as guidance for an appropriate wait count.

Parameter	How to Set It
Hung threads – Maximum number before restarting service	Specify the maximum number of hung threads that can be detected for a service before it is automatically restarted. **Notes** • Services are not automatically restarted unless you enable the *Restart service if hung threads detected?* parameter. • You should plan to run this script for a few days and collect data for average hung threads on the server to use as guidance for an appropriate maximum number of hung threads. The default is 5 hung threads.
Raise event if service restart succeeds?	Select **Yes** to raise an event if the attempt to restart services that have hung threads is successful. The default is Yes.
Event severity when service restart succeeds	Set the event severity level, from 1 to 40, to indicate the importance of an event in which a service is restarted successfully. The default is 25.
Raise event if service restart fails?	Select **Yes** to raise an event if the attempt to restart services that have hung threads fails. The default is Yes.
Event severity when service restart fails	Set the event severity level, from 1 to 40, to indicate the importance of an event in which a service is not restarted. The default is 5.
Raise event if hung thread log entries found?	Select **Yes** to raise an event if event log entries related to hung threads are found. The default is Yes.
Event severity when hung thread log entries found	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the log contains entries for hung threads. The default is 15.
Raise event if user name found in hung thread log entries?	Select **Yes** to raise an event if a user name is found in the hung thread log entries. The default is Yes.
Event severity when user name found in hung thread log entries	Set the event severity level, from 1 to 40, to indicate the importance of an event in which a user name is found in the hung thread log entries. The default is 15.
Blackberry High Availability Notification	
Raise event when BlackBerry STANDBY mode detected?	Select Yes to raise an event when the BlackBerry Enterprise Server is in STANDBY mode. The default is unselected.
Event severity when BlackBerry STANDBY mode detected	Set the severity level from 1 to 40 to indicate the importance of an event in which the BlackBerry Enterprise Server is in STANDBY mode. The default is 15.
Raise event when BlackBerry STANDBY mode changed to PRIMARY mode?	Select **Yes** to raise an event when the BlackBerry Enterprise Server mode has changed from STANDBY to PRIMARY. The default is Yes.
Event severity when BlackBerry mode changed to PRIMARY mode.	Set the severity level from 1 to 40 to indicate the importance of an event in which the BlackBerry Enterprise Server mode has changed to PRIMARY. The default is 15.
Monitor number of hung threads	
Event Notification	
Raise event if number of hung threads exceeds threshold?	Select **Yes** to raise an event if the number of hung threads for any service exceeds the threshold you set. The default is Yes.
Threshold – Maximum number of hung threads	Specify the maximum number of hung threads that can be detected for a service before an event is raised. The default is 5 hung threads.

Parameter	How to Set It
Event severity when number of hung threads exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of hung threads exceeds the threshold you set. The default is 5.
Data Collection	
Collect data for number of hung threads?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the total number of hung threads on the server. The default is unselected.
Monitor average thread wait count	
Data Collection	
Collect data for average thread wait count?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the average wait count for threads on the server. The default is unselected.

15.2 DebugLogSearch

Use this Knowledge Script to search the local debug logs for selected text strings. Restrict the types of debug log entries that raise an event by setting up regular-expression filters. Use the filtering parameters to include or exclude specific text strings. The script help includes examples of common filters. The table below identifies common regular-expression syntax.

NOTE: The search performed by this script can be highly resource-intensive and is intended for limited use only.

Each time this script runs, it checks the monitored debug log for entries matching your selection criteria and raises an event if matching entries are found. The event detail message returns the text of the log entries found. You can determine the number of entries to return in a single event using the *Number of matches per event* parameter.

This script runs two different ways, depending on the type of schedule you set. When you set an "interval" schedule (such as "Every 24 hours"), the first time this script runs, it sets a starting point for future searches. It does not return any results on the first iteration. As the script continues to run on an interval schedule, only new log entries created since the last interval are checked for matches against the text strings you entered for the filter parameters.

On any other type of schedule, such as "Run once," "Daily," or "Weekly", this script searches all the contents of all the debug log files on the selected Log resource objects. Each resource object often contains many such log files. Such a search may therefore be very resource-intensive.

When data collection is enabled, this script returns the number of log entries found, and the data point detail message returns the text of the log entries.

15.2.1 Using Regular Expression Filters

A regular expression is a pattern that describes a specific portion of text. Create regular-expression filters to limit the types of debug log entries that this Knowledge Script looks for. The filtering parameters let you use regular expressions to include or exclude specific text strings.

You must specify an **Include filter**. Optionally, you can also specify an **Exclude filter**. If you use both filters, the script returns log entries that contain any included search strings *and* do not contain any excluded strings.

The filtering parameters in this script support standard regular-expression syntax. The following table highlights common regular expression types and their usage.

For more information about regular expression syntax, see related Web sites such as www.wikipedia.org/wiki/Regular_expression or www.regular-expressions.info.

Regular Expression Type	Description
Literal	A literal expression consists of a single character that matches the first occurrence of that character in the text string. For example, if the expression is "`a`" and the text string is "`The gray cat is purring`," then the match is the "`a`" in "`gray`." All characters are literals except for the following: ".", "|", "*", "?", "+", "(", ")", "{", "}", "[", "]", "^", "$" and "\". These characters are treated as literals when preceded by a "\".

Regular Expression Type	Description
Wildcard	The dot wildcard "." matches any single character except line break characters. For example, the expression "`gr.y`" matches `gray`, `grey`, `gr%y`, and so on.
Repeat	A repeat is an expression that is repeated an arbitrary number of times. • A question mark, "**?**", indicates that the preceding character in the expression is optional. For example, the expression "`ba?`" returns "`b`" or "`ba`". • An asterisk, "*****", indicates that the preceding character is to be matched zero or more times. For example, the expression "`ba*`" returns all instances of "`b`", "`ba`", "`baaa`", and so on. • A plus sign, "+", indicates that the preceding character is to be matched one or more times. The expression "`ba+`" returns all instances of "`ba`" or "`baaaa`", for example, but not "`b`". • Curly braces, {}, indicate a specific amount of repetition. For example, the expression "`a{2}`" returns the letter "a" repeated exactly twice. The expression "`a{2,4}`" returns the letter "a" repeated between 2 and 4 times. The expression "`a{2,}`" returns the letter "a" repeated at least twice, with no upper limit. For example, the expression "`ba{2,4}`" returns "`baa`", "`baaa`", and "`baaaa`".
Non-Greedy Repeat	A non-greedy, or lazy, repeat matches the shortest possible string. Whenever the "extended" regular-expression syntax is in use (which is the default), non-greedy repeats are made possible by appending a "?" after the repeat. For example, the following greedy expression, "`<.+>`", returns `<EM>test</EM>` from the string `This is a <EM>test</EM>`. To return only the HTML tag, rewrite the expression as a non-greedy repeat, "`<.+?>`" which will match only the `<EM>` in the string.
Parentheses	Use parentheses, or round brackets, to group characters and then apply a repetition operator to the group. For example, the expression "`(ab)*`" returns all of the string "`abababab`".
Non-Marking Parentheses	Parentheses create sub-expressions, or backreferences, which store part of the string matched by the expression inside the parentheses. To use parentheses to group characters but not create backreferences, use non-marking parentheses: `(?:expression)`. For example, the following expression creates no backreference: `(?:ab)*`
Anchor	Anchors do not match characters. Instead, they match a position before, after, or between characters. They "anchor" the regular expression match at a certain point. • A "^" matches a position before the first character in a text string. For example, the expression "`^a`" applied to the text string `abc` returns "`a`" because "`a`" is at the beginning of the text string. The expression "`^b`" applied to the same text string returns no value, because "`b`" is not at the beginning of the text string. • A "$" matches right after the last character in a text string. For example, the expression "`c$`" applied to the text string abc returns "`c`" because "`c`" is at the end of the text string. The expression "`a$`" applied to the same string returns no value, because "`a`" is not at the end of the text string.

15.2.2 Resource Object

BlackBerry Log

15.2.3 Default Schedule

The default interval is **Run once**.

15.2.4 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Job Failure Notification	
Event severity when job fails	Set the event severity level, from 1 to 40, to indicate the importance of the event when the DebugLogSearch job fails. The default is 5.
Filter name	Specify a name to be used to associate data streams with the filter. If no filter is specified, the job ID is used. The default is none. **NOTE:** Do not specify a filter name that ends in “apostrophe s” (‘s). Filter names that end with “’s” prevent the data details from being shown and cause an error message.
Include filter	Only log entries that contain a text string that matches this regular expression filter are considered for data collection and events. By default, no filtering is applied. However, to run this script successfully, you must enter a value for this parameter. **Examples** • To find Error event IDs, which are five-digit numbers beginning with “1” (1xxxxx), type the following regular expression: `^\[1\d{4}\]*` • To find log entries related to hung thread error code 30038, type the following regular expression: `^\[30038\].*?Thread:*$` **NOTE:** This field is limited to 10,000 characters.
Exclude filter	Only log entries that do **not** contain a text string that matches this regular expression filter are considered for data collection and events. By default, no filtering is applied. **Examples** • To find all event IDs **except** for those belonging to Informational events, which are five-digit numbers beginning with “3” (3xxxx), type the following regular expression: `^\[3\d{4}\]*` • To find all log entries **except** for those related to threads, type the following regular expression: `Thread:+` **NOTE:** This field is limited to 10,000 characters.

Parameter	How to Set It
Number of matches per event	Set the maximum number of debug log entries that can be returned in each event report. For example, if this value is set to 25, and 57 debug log entries are found, three event reports are raised: two reports containing 25 events and one report containing seven events. The default is 50 entries per event message.
Raise event if log matches found?	Select **Yes** to raise an event when log entries that match the filtering criteria are found. The default is Yes.
Event severity when log matches found	Set the event severity level, from 1 to 40, to indicate the importance of an event in which log entries that match the filtering criteria are found. The default is 25.
Monitor number of matches	
Event Notification	
Raise event if number of matches exceeds threshold?	Select **Yes** to raise an event when the number of entries in a debug log file exceeds the threshold. The default is Yes.
Threshold – Maximum number of matches	Specify the maximum number of debug log entries that can match the filtering criteria before an event is raised. Enter a value from 0 to 32000 entries. The default is 10 entries.
Event severity when number of matches exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of debug log entries that match the filtering criteria exceeds the threshold. The default is 5.
Data Collection	
Collect data for number of matches?	Select **Yes** to collect data for charts and reports. If enabled, data collection, returns the number of matching debug log entries. The data details include the text of the entries. The default is unselected.

15.3 DebugLogSize

Use this Knowledge Script to monitor the size, in MB, of BlackBerry debug logs.

If data collection is enabled, a different data stream is created for each log file. The total size on disk of all monitored logs is also returned. An event is raised if the size threshold you set is exceeded.

This script can automatically purge log files when a log exceeds both a size and age threshold you set. An event is raised if an automatic purge is performed.

15.3.1 Resource Object

BlackBerry Log

15.3.2 Default Schedule

The default interval for this script is **Every 24 hours**.

15.3.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Job Failure Notification	
Event severity when job fails	Set the event severity level, from 1 to 40, to indicate the importance of the event when the DebugLogSize job fails. The default is 5.
Automatically purge log files?	Select **Yes** to automatically purge a log file if its size exceeds the *Log file size* and if its age exceeds the *Log file age* you set. The default is unselected.
Log file size – Maximum size before purging	Specify the largest size that the log file can attain before it is purged. **NOTE:** The *Log file age* value must also be met before the purge is performed. The default is 100 MB.
Log file age – Maximum age before purging	Specify the maximum age that the log file can attain before it is purged. **NOTE:** The *Log file size* value must also be met before the purge is performed. The default is 180 days.
Raise event if log files purged?	Select **Yes** to raise an event if a log file exceeds the size and age limits you set and is subsequently purged. The default is Yes.
Event severity when log files purged	Set the event severity level, from 1 to 40, to indicate the importance of an event in which a log file is purged. The default is 25.
Monitor size of log file	
Event Notification	
Raise event if size of log file exceeds threshold?	Select **Yes** to raise an event if the log file size exceeds the threshold you set.

Parameter	How to Set It
Threshold – Maximum size of log file	Specify the maximum size, in Megabytes, that the monitored log file can reach before an event is raised. The default is 100 MB.
Event severity when size of log file exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the size of the log file exceeds the threshold you set. The default is 5.
Data Collection	
Collect data for size of log file?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the size of the log file. The default is unselected.
Monitor total size of all monitored log files	
Event Notification	
Raise event if size of all monitored log files exceeds threshold?	Select **Yes** to raise an event if the log file size exceeds the threshold you set. The default is Yes.
Threshold – Maximum total size of all monitored log files	Specify the maximum size, in Megabytes, that the total of all monitored log files can reach before an event is raised. The default is 1000 MB.
Event severity when total size of all monitored log files exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the combined size of all log files exceeds the threshold you set. The default is 5.
Data Collection	
Collect data for total size of all monitored log files?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the total size of all the log files selected for monitoring. The default is unselected.
Monitor number of log files purged	
Event Notification	
Raise event if number of log files purged exceeds threshold?	Select **Yes** to raise an event if the number of log files automatically purged exceeds the threshold you set. The default is Yes.
Threshold – Maximum number of log files purged	Specify the maximum number of log files that can be purged because they have exceeded the size and age thresholds before an event is raised. The default is 10 log files purged.
Event severity when number of log files purged exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of purged log files exceeds the threshold. The default is 5.
Data Collection	
Collect data for number of log files purged?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the number of log files that were automatically purged when they exceeded the size and age thresholds you set. The data details contain the file names of logs that were removed. The default is unselected.

15.4 HungThreads

Use this Knowledge Script to monitor the BlackBerry Enterprise Server service for hung threads. Hung threads decrease the number of requests that can be concurrently processed by the service. Any thread that starts and then does not finish is considered hung.

This script raises an event when hung threads are detected and when the number of hung threads exceeds the threshold you set. You also have the option to restart the hung service automatically. If you choose to collect data, this script returns data about the number of hung threads, the thread ID, and the wait count.

NOTE:

- This script does not search for hung threads associated with MDS, Collaboration, MailStore, and Administration services.
- This script monitors BlackBerry Attachment and BlackBerry Router services for hung threads if the BlackBerry Enterprise Server is running in STANDBY mode.

The wait count value that you set in the *Wait count – Cycles to wait before restarting service* parameter refers to the number of cycles that a thread has been blocked. If you enable data collection, this script returns the average wait count for the server. Use this statistic as guidance when you set a wait count.

To find hung threads, this script searches for the following event IDs in the BlackBerry Enterprise Server event logs. These IDs are defined in the following table. You can also configure this script to look for additional event IDs. For more information, see "Monitoring Additional Event IDs" on page 584.

Event ID	Explanation
10019 – All worker threads seem to be blocked	All worker threads are unresponsive and cannot be allocated for work.
10165 – Thread: main timer thread appears to be blocked	RIM provides little information about this event or what it signifies. The event text mentions a "Queuing alarm" from BlackBerry Messaging.
20266 – At least one worker thread seems to be blocked (*N*)	One of the worker threads is blocked and unable to process mail. The parameter in parentheses indicates a wait count. The value of this parameter indicates how long the thread has been unresponsive: • 1 = 10 minutes • 2 = 20 minutes • 3 = 30 minutes **NOTE:** The BlackBerry Enterprise Server should automatically free hung threads and resume mail processing unless the Exchange Server is down.
20315 – Thread: *** No Response *** Thread Id=0xFC, Handle=0x238, WaitCount=7, SCS thread not responding, SCS - duplicate PIN check	An unresponsive worker thread has been found. Until it becomes unblocked, the thread cannot complete its work. The WaitCount indicates how long the thread has been in this state. In situations where the WaitCount value exceeds 10, the thread is unlikely to recover on its own.
30000 – Hung threads detected	An event with the 30000 ID contains the words "hung threads detected".
30038 – {0xD3} Thread: *** No Response ***	An unresponsive worker thread has been located. Until it becomes unblocked, the thread cannot complete its work. The condition will most likely be resolved without the need to restart the BlackBerry Enterprise Server.

Event ID	Explanation
50020 – {0xC3} Some worker threads have been blocked for 6 health checks	Worker threads that have been unresponsive for six health checks (60 minutes) have been found.
50023 – All worker threads of one of the pools seem to be blocked	All the threads assigned to a particular Exchange server are not responding. This could indicate a communication issue with that Exchange server, or it could indicate more widespread issues.

15.4.1 Resource Object

BlackBerry Enterprise Server service

15.4.2 Default Schedule

The default interval is **Every 10 minutes**.

15.4.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Job Failure Notification	
Event severity when job fails	Set the event severity level, from 1 to 40, to indicate the importance of an event when the HungThreads job fails. The default is 5.
Restart service if hung threads detected?	Select **Yes** to have this script automatically restart services that have hung threads. Any service that has hung threads that have not become unblocked after the wait count has expired (see the *Wait count* parameter) will then be restarted. The default is unselected. When you enable this parameter, a service may be restarted automatically; however, the blocked thread must also meet one of the following conditions: • One (or both) of the following events is found in the event log: – 10019: All worker threads seem to be blocked – 50023: All worker threads of one of the pools seem to be blocked • The wait count you set using the *Wait count – Cycles to wait before restarting service* parameter has been exceeded by one of the hung threads that was found. • The value you set for the *Hung threads – Maximum number before restarting service* parameter has been exceeded by the number of hung threads found in the server event log.
Wait count – Cycles to wait before restarting service	Set a wait count for each hung thread. This script waits the specified number of cycles to detect whether hung threads become unblocked. The default is 3 cycles. **NOTE:** You should run this script for a few days and collect data for average wait count on the server to use as guidance for an appropriate wait count.

Parameter	How to Set It
Hung threads – Maximum number before restarting service	Specify the maximum number of hung threads that can be detected for a service before it is automatically restarted. **Notes** • Services are not automatically restarted unless you enable the *Restart service if hung threads detected?* parameter. • You should plan to run this script for a few days and collect data for average hung threads on the server to use as guidance for an appropriate maximum number of hung threads. The default is 5 hung threads.
Raise event if service restart succeeds?	Select **Yes** to raise an event if the attempt to restart services that have hung threads is successful. The default is Yes.
Event severity when service restart succeeds	Set the event severity level, from 1 to 40, to indicate the importance of an event in which services are restarted successfully. The default is 25.
Raise event if service restart fails?	Select Yes to raise an event if the attempt to restart services that have hung threads fails. The default is Yes.
Event severity when service restart fails	Set the event severity level, from 1 to 40, to indicate the importance of an event in which services cannot be restarted. The default is 5.
Raise event if hung thread log entries found?	Select **Yes** to raise an event if event log entries related to hung threads are found. The default is Yes.
Event severity when hung thread log entries found	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the log contains entries for hung threads. The default is 15.
Raise event if user name found in hung thread log entries?	Select **Yes** to raise an event if a user name is found in the hung thread log entries. The default is Yes.
Event severity when user name found in hung thread log entries	Set the event severity level, from 1 to 40, to indicate the importance of an event in which a user name is found in the hung thread log entries. The default is 15.
Blackberry High Availability Notification	
Raise event when BlackBerry STANDBY mode detected?	Select Yes to raise an event when the BlackBerry Enterprise Server is in STANDBY mode. The default is unselected.
Event severity when BlackBerry STANDBY mode detected	Set the severity level from 1 to 40 to indicate the importance of an event in which the BlackBerry Enterprise Server is in STANDBY mode. The default is 15.
Raise event when BlackBerry STANDBY mode changed to PRIMARY mode?	Select **Yes** to raise an event when the BlackBerry Enterprise Server mode has changed from STANDBY to PRIMARY. The default is Yes.
Event severity when BlackBerry mode changed to PRIMARY mode.	Set the severity level from 1 to 40 to indicate the importance of an event in which the BlackBerry Enterprise Server mode has changed to PRIMARY. The default is 15.
Monitor number of hung threads	
Event Notification	
Raise event if number of hung threads exceeds threshold?	Select **Yes** to raise an event if the number of hung threads for any service exceeds the threshold you set. The default is Yes.
Threshold – Maximum number of hung threads	Specify the maximum number of hung threads that can be detected for a service before an event is raised. The default is 5 hung threads.

Parameter	How to Set It
Event severity when number of hung threads exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of hung threads exceeds the threshold you set. The default is 5.
Data Collection	
Collect data for number of hung threads?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the total number of hung threads on the server. The default is unselected.
Monitor average thread wait count	
Data Collection	
Collect data for average thread wait count?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the average wait count for threads on the server. The default is unselected.

15.4.4 Monitoring Additional Event IDs

By default, the BlackberryAgent and HungThreads Knowledge Scripts look for the following event IDs in the events logs for the BlackBerry agent and the BlackBerry Enterprise Server service:

- 10019
- 10165
- 20266
- 20315
- 30000
- 30038
- 50020
- 50023

You can customize these scripts to look for additional event IDs by altering the `beserrorcodes.xml` file, which is installed by default in `ProgramFiles\AppManager\NetIQ\bin`. In the XML file, you can indicate which event ID to look for and assign an event action to an event ID.

The `beserrorcodes.xml` file has the following format:

```
<?xml version="1.0" encoding="utf-8" ?>
<BES>
    <HungThreads>
      <!-- The Event tag value should be a Perl regular expression for search criteria.-->
      <!-- Action="Restart" will trigger service to be restarted-->
      <Event Action="Restart">^\[10019\].*?All worker threads seem to be blocked.*$</Event>
      <Event>^\[10165\].*?Thread: main timer thread appears to be blocked.*$ </Event>
      <Event>^\[20266\].*?At least one worker thread seems to be blocked.*$</Event>
      <Event>^\[20315\].*?Thread: \*\*\* No Response \*\*\* Thread Id=.*?, Handle=.*?, WaitCount=\d+.*$
</Event>
      <Event>^\[30038\].*?Thread: \*\*\* No Response \*\*\*.*$</Event>
      <Event>^\[50020\].*?Some worker threads have been blocked for \d+ health checks.*$ </Event>
      <Event Action="Restart">^\[50023\].*?All worker threads of one of the pools seem to be blocked.*$
</Event>
      <Event>^\[30000\].*?hung threads detected.*$</Event>
   </HungThreads>
</BES>
```

- where `<BES>` is the document name and a mandatory section.

- where `<HungThreads>` is a mandatory section for the HungThreads and BlackberryAgent Knowledge Scripts.
- where `<Event>` identifies the search criteria.
- where `<Event Action="Restart">` indicates that a service will be restarted if a service's log file contains at least one entry of this event in its log file.

To monitor additional event IDs:

1. Navigate to `ProgramFiles\AppManager\NetIQ\bin` and open `beserrorcodes.xml` in an XML editor.
2. Add a new row using the format shown in the graphic above. Use a Perl regular expression to indicate the event ID you want to monitor, and assign an event action if necessary.
3. Save and close the file. Do not save it with a new name.

15.5 InactiveUsers

Use this Knowledge Script to determine which BlackBerry users have been inactive for a specified period of time.

Inactivity is determined by the times of the last message forwarded or of the last device interaction. You can set thresholds for each inactivity measurement. If you enable data collection, this script returns the following data streams for each user:

- The number of days since the last device interaction
- The number of days since the last message forwarded to this user

NOTE: This script currently is not supported for use with BES 10 and later.

15.5.1 Resource Object

BlackBerry Server

15.5.2 Default Schedule

The default schedule is **Every 24 hours**.

15.5.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Job Failure Notification	
Event severity when job fails	Set the event severity level, from 1 to 40, to indicate the importance of the event when the InactiveUsers job fails. The default is 5.
Blackberry High Availability Notification	
Raise event when BlackBerry STANDBY mode detected?	Select Yes to raise an event when the BlackBerry Enterprise Server is in STANDBY mode. The default is unselected.
Event severity when BlackBerry STANDBY mode detected	Set the severity level from 1 to 40 to indicate the importance of an event in which the BlackBerry Enterprise Server is in STANDBY mode. The default is 15.
Raise event when BlackBerry STANDBY mode changed to PRIMARY mode?	Select **Yes** to raise an event when the BlackBerry Enterprise Server mode has changed from STANDBY to PRIMARY. The default is Yes.
Event severity when BlackBerry mode changed to PRIMARY mode.	Set the severity level from 1 to 40 to indicate the importance of an event in which the BlackBerry Enterprise Server mode has changed to PRIMARY. The default is 15.

Parameter	How to Set It
Database login	If you want to use SQL authentication, supply login information to access the BlackBerry Enterprise Server database. **NOTE:** This information must already be configured in AppManager Security Manager.
Mirror database login	To use SQL authentication in a mirrored database environment, supply login information to access the BlackBerry Enterprise Server secondary database. If left blank, Windows authentication is used. **NOTE:** This information must already be configured in AppManager Security Manager.
Maximum number of users to record data streams for	Specify the maximum number of users to include when collecting data. When data collection is enabled, this script returns the time of the last message forwarded to each user on the server. This parameter sets an upper limit on the number of users for whom such data should be collected and returned. The default is 100 users.
Monitor time since last message forwarded	
Event Notification	
Raise event if time since last message forwarded exceeds threshold?	Select **Yes** to raise an event if the time since a user account last forwarded a message exceeds the threshold you set. The default is Yes.
Threshold – Maximum time since last message forwarded	Specify the maximum number of days that a user can be inactive (defined as the last time that user's account has forwarded a message) before an event is raised. The default is 30 days.
Event severity when time since last message forwarded exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of days that a user has been inactive exceeds the threshold. The default is 5.
Data Collection	
Collect data for time since last message forwarded?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the time that the last message was forwarded to each user. The default is unselected.
Monitor time since last device interaction?	
Event Notification	
Raise event if time since last device interaction exceeds threshold?	Select **Yes** to raise an event if the time since a user last interacted with a BlackBerry device exceeds the threshold you set. The default is Yes.
Threshold – Maximum time since last device interaction	Specify the maximum number of days that a user can be inactive (defined as the last time a device interaction was associated with that user) before an event is raised. The default is 30 days.
Event severity when time since last device interaction exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of days a user is inactive exceeds the threshold you set. The default is 5.
Data Collection	
Collect data for time since last device interaction?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the time of the last device interaction for each user. The default is unselected.

15.6 MDSConnections

Use this Knowledge Script to monitor the BlackBerry Mobile Data Service (MDS) for the number of device and push connections, as well as the maximum packet size and the number of packets for these connections.

Although they both monitor the Mobile Data Service, this script is independent of the MDSFailures Knowledge Script. Therefore, failures may be occurring even if this script shows that connections are succeeding.

MDS usage statistics are stored by the BlackBerry configuration database every 15 minutes. Therefore, this script cannot operate at intervals of less than 15 minutes. Furthermore, this script collects data only for fully completed intervals. For example, if the script is scheduled to run at 1:35 on a 15-minute interval, only the last completed 15-minute interval is recorded, for the period of 1:15 to 1:30.

If data is collected, this script returns the number of connections, the total packet size in bytes, and the number of packets from connections.

Even if you enable data collection, this script may not collect any data. At times, this script returns "null" data, which indicates that the database query returned no rows.

15.6.1 Resource Object

BlackBerry Server

15.6.2 Default Schedule

The default schedule is **Every 15 minutes**.

15.6.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Job Failure Notification	
Event severity when job fails	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the MDSConnections job fails. The default is 5.
Blackberry High Availability Notification	
Raise event when BlackBerry STANDBY mode detected?	Select Yes to raise an event when the BlackBerry Enterprise Server is in STANDBY mode. The default is unselected.
Event severity when BlackBerry STANDBY mode detected	Set the severity level from 1 to 40 to indicate the importance of an event in which the BlackBerry Enterprise Server is in STANDBY mode. The default is 15.
Raise event when BlackBerry STANDBY mode changed to PRIMARY mode?	Select **Yes** to raise an event when the BlackBerry Enterprise Server mode has changed from STANDBY to PRIMARY. The default is Yes.

Parameter	How to Set It
Event severity when BlackBerry mode changed to PRIMARY mode.	Set the severity level from 1 to 40 to indicate the importance of an event in which the BlackBerry Enterprise Server mode has changed to PRIMARY. The default is 15.
Database login	To use SQL authentication, supply login information to access the BlackBerry Enterprise Server database. **NOTE:** This information must already be configured in AppManager Security Manager.
Mirror database login	To use SQL authentication in a mirrored database environment, supply login information to access the BlackBerry Enterprise Server secondary database. If left blank, Windows authentication is used. **NOTE:** This information must already be configured in AppManager Security Manager.
Monitor number of device connections?	
Event Notification	
Raise event if number of device connections exceeds threshold?	Select **Yes** to raise an event if the number of device connections to the MDS exceeds the threshold you set. The default is Yes.
Threshold – Maximum number of device connections	Specify the maximum number of device connections that can be running to the MDS before an event is raised. The default is 50 connections.
Event severity when number of device connections exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of device connections exceeds the threshold. The default is 5.
Data Collection	
Collect data for number of device connections?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the number of device connections to the MDS. The default is unselected.
Monitor number of push connections?	
Event Notification	
Raise event if number of push connections exceeds threshold?	Select **Yes** to raise an event if the number of push connections to the MDS exceeds the threshold you set. The default is Yes.
Threshold – Maximum number of push connections	Specify the maximum number of push connections that can be running to the MDS before an event is raised. The default is 50 connections.
Event severity when number of push connections exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of push connections exceeds the threshold. The default is 5.
Data Collection	
Collect data for number of push connections?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the number of push connections to the MDS. The default is unselected.
Monitor packet size for device connections?	
Event Notification	
Raise event if packet size for device connections exceeds threshold?	Select **Yes** to raise an event if the maximum packet size for device connections to the MDS exceeds the threshold you set. The default is Yes.

Parameter	How to Set It
Threshold – Maximum packet size for device connections	Specify the maximum size, in Kilobytes, of a packet sent in a device connection to the MDS before an event is raised. The default is 2048 KB.
Event severity when packet size for device connections exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which packet size exceeds the threshold. The default is 5.
Data Collection	
Collect data for packet size for device connections?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the total packet size for device connections and the number of packets from device connections. The default is unselected.
Monitor packet size for push connections?	
Event Notification	
Raise event if packet size for push connections exceeds threshold?	Select **Yes** to raise an event if the maximum packet size for push connections to the MDS exceeds the threshold you set. The default is Yes.
Threshold – Maximum packet size for push connections	Specify the maximum size, in Kilobytes, of a packet sent in a push connection to the MDS before an event is raised. The default is 2048 KB.
Event severity when packet size for push connections exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which packet size exceeds the threshold. The default is 5.
Data Collection	
Collect data for packet size for push connections?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the total packet size for push connections and the number of packets from push connections. The default is unselected.
Monitor number of packets from device connections?	
Event Notification	
Raise event if number of packets from device connections exceeds threshold?	Select **Yes** to raise an event if the number of packets from device connections to the MDS exceeds the threshold you set. The default is Yes.
Threshold – Maximum number of packets from device connections	Specify the maximum number of packets from device connections to the MDS before an event is raised. The default is 1024 packets.
Event severity when number of packets from device connections exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of packets exceeds the threshold. The default is 5.
Data Collection	
Collect data for number of packets from device connections?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the number of packets from device connections. The default is unselected.
Monitor number of packets from push connections?	
Event Notification	
Raise event if number of packets from push connections exceeds threshold?	Select **Yes** to raise an event if the number of packets from push connections to the MDS exceeds the threshold you set. The default is Yes.

Parameter	How to Set It
Threshold – Maximum number of packets from push connections	Specify the maximum number of packets from push connections to the MDS before an event is raised. The default is 1024 packets.
Event severity when number of packets from push connections exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of packets exceeds the threshold. The default is 5.
Data Collection	
Collect data for number of packets from push connections?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the number of packets from push connections. The default is unselected.

15.7 MDSFailures

Use this Knowledge Script to monitor the BlackBerry Mobile Data Service (MDS) for connection failures, device authentication failures, and bad packets sent to handheld devices.

Although they both monitor the Mobile Data Service, this script is completely independent of the MDSConnections Knowledge Script. Therefore, this script may indicate that failures are occurring even if the MDSConnections Knowledge Script shows that connections are succeeding.

MDS usage statistics are stored by the BlackBerry config database every 15 minutes. Therefore, this script cannot operate at intervals of less than 15 minutes. Furthermore, this script collects data only for fully completed intervals. For example, if the script is scheduled to run at 1:35 on a 15-minute interval, only the last completed 15-minute interval is recorded, for the period of 1:15 to 1:30.

If data is collected, this script returns the number of failed and truncated connections, the number of authentication failures, and the number of refused and invalid packets.

Even if you enable data collection, this script may not collect any data. At times, this script returns "null" data, which indicates that the database query returned no rows.

15.7.1 Resource Object

BlackBerry Server

15.7.2 Default Schedule

The default schedule is **Every 15 minutes**.

15.7.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Job Failure Notification	
Event severity when job fails	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the MDSFailures job fails. The default is 5.
Blackberry High Availability Notification	
Raise event when BlackBerry STANDBY mode detected?	Select Yes to raise an event when the BlackBerry Enterprise Server is in STANDBY mode. The default is unselected.
Event severity when BlackBerry STANDBY mode detected	Set the severity level from 1 to 40 to indicate the importance of an event in which the BlackBerry Enterprise Server is in STANDBY mode. The default is 15.
Raise event when BlackBerry STANDBY mode changed to PRIMARY mode?	Select **Yes** to raise an event when the BlackBerry Enterprise Server mode has changed from STANDBY to PRIMARY. The default is Yes.

Parameter	How to Set It
Event severity when BlackBerry mode changed to PRIMARY mode.	Set the severity level from 1 to 40 to indicate the importance of an event in which the BlackBerry Enterprise Server mode has changed to PRIMARY. The default is 15.
Database login	To use SQL authentication, supply login information to access the BlackBerry Enterprise Server database. If left blank, Windows authentication is used. **NOTE:** This information must already be configured in AppManager Security Manager.
Mirror database login	To use SQL authentication in a mirrored database environment, supply login information to access the BlackBerry Enterprise Server secondary database. If left blank, Windows authentication is used. **NOTE:** This information must already be configured in AppManager Security Manager.
Monitor number of failed connections	
Event Notification	
Raise event if number of failed connections exceeds threshold?	Select **Yes** to raise an event if the number of failed connections to the MDS exceeds the threshold you set. The default is Yes.
Threshold – Maximum number of failed connections	Specify the maximum number of connections to the MDS that can fail before an event is raised. The default is 25 connections.
Event severity when number of failed connections exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of failed connections exceeds the threshold. The default is 5.
Data Collection	
Collect data for number of failed connections?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the number of failed connections to the MDS. The default is unselected.
Monitor number of truncated connections	
Event Notification	
Raise event if number of truncated connections exceeds threshold?	Select **Yes** to raise an event if the number of truncated connections to the MDS exceeds the threshold you set. The default is Yes. A truncated connection is one that starts but stops unexpectedly.
Threshold – Maximum number of truncated connections	Specify the maximum number of connections to the MDS that can be truncated before an event is raised. The default is 25 connections.
Event severity when number of truncated connections exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of truncated connections exceeds the threshold. The default is 5.
Data Collection	
Collect data for number of truncated connections?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the number of truncated connections to the MDS. The default is unselected.
Monitor number of authentication failures	
Event Notification	
Raise event if number of authentication failures exceeds threshold?	Select **Yes** to raise an event if the number of authentication failures at the MDS exceeds the threshold you set. The default is Yes.

Parameter	How to Set It
Threshold – Maximum number of authentication failures	Specify the maximum number of authentication failures that can occur at the MDS before an event is raised. The default is 10 failures.
Event severity when number of authentication failures exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of authentications failures exceeds the threshold you set. The default is 5.
Data Collection	
Collect data for number of authentication failures?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the total number of authentication failures at the MDS. The default is unselected.
Monitor number of refused packets	
Event Notification	
Raise event if number of refused packets exceeds threshold?	Select **Yes** to raise an event if the number of packets refused by the MDS exceeds the threshold you set. The default is Yes.
Threshold – Maximum number of refused packets	Specify the maximum number of packets that can have been refused by the MDS before an event is raised. The default is 1024 packets.
Event severity when number of refused packets exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of refused packets exceeds the threshold you set. The default is 5.
Data Collection	
Collect data for number of refused packets?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the number of packets refused by the MDS. The default is unselected.
Monitor number of invalid packets	
Event Notification	
Raise event if number of invalid packets exceeds threshold?	Select **Yes** to raise an event if the number of invalid packets received by the MDS exceeds the threshold you set. The default is Yes.
Threshold – Maximum number of invalid packets	Specify the maximum number of invalid packets that can be received by the MDS before an event is raised. The default is 1024 packets.
Event severity when number of invalid packets exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of invalid packets exceeds the threshold you set. The default is 5.
Data Collection	
Collect data for number of invalid packets?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the total number of invalid packets received by the MDS. The default is unselected.

15.8 MessageSize

Use this Knowledge Script to find the average size, in KB, of the messages forwarded and those that were replied to with text per user on a BlackBerry server. This script raises an event if the average message size exceeds the threshold you set.

NOTE: This script currently is not supported for use with BES 10 and later.

15.8.1 Resource Object

BlackBerry server

15.8.2 Default Schedule

The default schedule is **Every hour**.

15.8.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How To Set It
General Settings	
Job Failure Notification	
Event severity when job fails	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the MessageSize job fails. The default is 40.
Maximum number of users to record data streams for	Specify the maximum number of users on the selected BlackBerry server for whom this Knowledge Script should create data streams. The default is 100.
Blackberry High Availability Notification	
Raise event when BlackBerry STANDBY mode detected?	Select Yes to raise an event when the BlackBerry Enterprise Server is in STANDBY mode. The default is unselected.
Event severity when BlackBerry STANDBY mode detected	Set the severity level from 1 to 40 to indicate the importance of an event in which the BlackBerry Enterprise Server is in STANDBY mode. The default is 15.
Raise event when BlackBerry STANDBY mode changed to PRIMARY mode?	Select **Yes** to raise an event when the BlackBerry Enterprise Server mode has changed from STANDBY to PRIMARY. The default is Yes.
Event severity when BlackBerry mode changed to PRIMARY mode.	Set the severity level from 1 to 40 to indicate the importance of an event in which the BlackBerry Enterprise Server mode has changed to PRIMARY. The default is 15.
Monitor size of forwarded messages for a user	
Event Notification	
Raise event if average size of forwarded messages exceeds threshold?	Select **Yes** to raise an event if the average size of messages forwarded to a user on the BlackBerry server exceeds the threshold you set. The default is Yes.

Parameter	How To Set It
Threshold – Maximum average size of forwarded messages	Specify the maximum average size that messages forwarded to a user on the BlackBerry server can reach before an event is raised. The default is 1024 KB.
Event severity when average size of forwarded messages exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the average size of forwarded messages exceeds the threshold you set. The default is 5.
Data Collection	
Collect data for average size of forwarded messages for a user?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the average size, in KB, of messages forwarded per user on the BlackBerry server. The default is unselected.
Monitor size of messages replied to with text for a user	
Event Notification	
Raise event if average size of messages replied to with text exceeds threshold?	Select **Yes** to raise an event if the average size of messages to which replies with text were sent by a user on the BlackBerry server exceeds the threshold you set. The default is unselected.
Threshold – Maximum average size of messages replied to with text	Specify the maximum average size that messages to which replies with text were sent can reach for a user on the BlackBerry server before an event is raised. The default is 25 connections.
Event severity when average size of messages replied to with text exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the average size of messages exceeds the threshold you set. The default is 5.
Data Collection	
Collect data for average size of messages replied to with text for a user?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the average size, in KB, of messages to which replies with text were sent by a user on the BlackBerry server. The default is unselected.

15.9 OrphanedUsers

Use this script to determine which BlackBerry users have been orphaned. “Orphaned” users are those whose BlackBerry accounts no longer have matching, valid Exchange accounts.

If data collection is enabled, this script returns the number of BlackBerry users that have been orphaned. Further information about each orphaned user is returned in the data details for the data stream.

You must have a valid Messaging Application Programming Interface (MAPI) profile set up on the server where you are running the job. This profile is part of the requirements for installing the BlackBerry server. Consult your BlackBerry Enterprise Server documentation for instructions about obtaining the name of this profile, which you need to enter for the *MAPI profile* parameter.

NOTE: BES 10 no longer uses MAPI profile. However, a MAPI Profile is required to check and retrieve information from user mailboxes. Therefore, you need to manually create a MAPI profile on a BES Server machine and associate it with the Exchange Server. To create a MAPI profile:

1. Download `ExchangeMapiCdo.EXE` from Microsoft Exchange Server MAPI Client and Collaboration Data Objects 1.2.1 and install it.
2. Run the following utility from the `\AppManager\bin\BES` directory:

   ```
   prof.exe -s Exchangeservername -m usermailboxname -NOTM -p MAPIprofilename
   -registry
   ```

15.9.1 Resource Object

BlackBerry Server

15.9.2 Default Schedule

The default schedule is **Every 24 hours**.

15.9.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Job Failure Notification	
Event severity when job fails	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the OrphanedUsers job fails. The default is 5.
MAPI profile	Enter the name of the MAPI profile you are using on the BlackBerry server.
Blackberry High Availability Notification	
Raise event when BlackBerry STANDBY mode detected?	Select Yes to raise an event when the BlackBerry Enterprise Server is in STANDBY mode. The default is unselected.

Parameter	How to Set It
Event severity when BlackBerry STANDBY mode detected	Set the severity level from 1 to 40 to indicate the importance of an event in which the BlackBerry Enterprise Server is in STANDBY mode. The default is 15.
Raise event when BlackBerry STANDBY mode changed to PRIMARY mode?	Select **Yes** to raise an event when the BlackBerry Enterprise Server mode has changed from STANDBY to PRIMARY. The default is Yes.
Event severity when BlackBerry mode changed to PRIMARY mode.	Set the severity level from 1 to 40 to indicate the importance of an event in which the BlackBerry Enterprise Server mode has changed to PRIMARY. The default is 15.
Database login	To use SQL authentication, supply login information to access the BlackBerry Enterprise Server database. If left blank, Windows authentication is used. **NOTE:** This information must already be configured in AppManager Security Manager.
Mirror database login	To use SQL authentication in a mirrored database environment, supply login information to access the BlackBerry Enterprise Server secondary database. If left blank, Windows authentication is used. **NOTE:** This information must already be configured in AppManager Security Manager.
Raise event if orphaned users exist?	Select **Yes** to raise an event if any orphaned users are found. The default is Yes.
Event severity when orphaned users exist	Set the event severity level, from 1 to 40, to indicate the importance of an event in which orphaned users are found. The default is 5.
Monitor number of orphaned users	
Event Notification	
Raise event if number of orphaned users exceeds threshold?	Select **Yes** to raise an event if the number of orphaned users exceeds the threshold you set. The default is Yes.
Threshold – Maximum number of orphaned users	Specify the maximum number of orphaned users that can be found before an event is raised. The default is 10 orphaned users.
Event severity when number of orphaned users exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of orphaned users exceeds the threshold you set. The default is 5.
Data Collection	
Collect data for number of orphaned users?	Select **Yes** to collect data for charts and reports. If enabled, returns the number of orphaned users on the BlackBerry server. The data details include information about each orphaned user. The default is unselected.

15.10 Report_EndToEndResponseTime

Use this Knowledge Script to generate a report about the round-trip response time for an e-mail message. This report includes a measurement of the round-trip response time for a message to travel from a client mailbox, through a selected Exchange Server, to a BlackBerry Enterprise Server handheld device, and for the handheld device to send a response.

This report uses data collected by the ResponseTime Knowledge Script.

NOTE: Note You may see a gap in data points if this report is run on a BlackBerry Enterprise Server on which the failover status changes from STANDBY to PRIMARY.

15.10.1 Resource Object

Report agent

15.10.2 Default Schedule

The default schedule is **Run once**.

15.10.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Data Source	
Select computer(s)	Select the computers for your report.
Select the style	Select the style for the first page of the report: • **By computer** provides links to pages showing the data collected from individual computers (each page shows all the data streams collected from a single computer) • **By data stream** provides links to pages showing a side-by-side comparison of values for the same data stream collected from different computers (each page shows, for example, the value of the *NT_CpuResource-All Threads(#)* data stream from each computer) • **By computer and data stream** provides links to pages showing a single data stream collected from a computer • **All data streams on one page** generates a report with all data on a single page
Select time range	Set a specific or sliding time range for data included in your report.
Select peak weekday(s)	Select the days of the week to include in your report.
Aggregation by	Select the aggregation method for the data in your report: • Minute • Hour • Day

Parameter	How to Set It
Aggregation interval	Select the interval by which the data in your report is aggregated. Possible values range from 1 to 90.
Statistics to show per period	Select a statistical method by which to display data in the report: • **Average**: The average value of data points for the aggregation interval (for example, the average value for 1 hour) • **Minimum**: The minimum value of data points for the aggregation interval • **Maximum**: The maximum value of data points for the aggregation interval • **Count**: The number of data points for the aggregation interval • **Sum**: The total value of data points for the aggregation interval • **3Sigma**: The average + (3 * standard deviation) and average - (3 * standard deviation) • **Std**: The standard deviation • **Box**: Lower fence, 25% point, median, 75% point, and upper fence for the aggregation interval • **Open**: The first value for the aggregation interval • **Close**: the last value for the aggregation interval
Report Settings	
Include parameter help table?	Select **yes** to include a table in the report that lists parameter settings for the report script. The default is yes.
Include table?	Select **yes** to include a table of data stream values in the report. The default is yes.
Include chart?	Select **yes** to include a chart of data stream values in the report. The default is yes.
Select chart style	Define the graphic properties of the charts in your report.
Select output folder	Set properties for the output folder.
Add job ID to output folder name?	Select **yes** to append the job ID to the name of the output folder. A job ID is helpful to make the correlation between a specific instance of a Report Script and the corresponding report. The default is no.
Select properties	Set miscellaneous report properties as needed.
Add timestamp to title?	Select **yes** to append a timestamp to the title of the report, making each title unique. The timestamp is made up of the date and time the report was generated. Adding a timestamp is useful in order to run consecutive iterations of the same report without overwriting previous output. The default is no.
Event Notification	
Raise event when report succeeds?	Select **yes** to raise an event when the report is successfully generated. The default is yes.
Event severity for report success	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report is successfully generated. The default is 35.
Event severity for report with no data	Set the severity level, from 1 to 40, to indicate the importance of an event in which the generated report contains no data. The default is 25.
Event severity for report failure	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report cannot be generated. The default is 5.

15.11 Report_LastUserCount

Use this Knowledge Script to generate a report about the last recorded value for the user count and the percentage of licenses in use for a BlackBerry Enterprise Server. This script uses data collected by the UserCount Knowledge Script.

NOTE: Note You may see a gap in data points if this report is run on a BlackBerry Enterprise Server on which the failover status changes from STANDBY to PRIMARY.

15.11.1 Resource Object

Report agent

15.11.2 Default Schedule

The default schedule is **Run once**.

15.11.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Data Source	
Select computer(s)	Select the computers for your report.
Select the style	Select the style for the first page of the report: • **By computer** provides links to pages showing the data collected from individual computers (each page shows all the data streams collected from a single computer) • **By data stream** provides links to pages showing a side-by-side comparison of values for the same data stream collected from different computers (each page shows, for example, the value of the *NT_CpuResource-All Threads(#)* data stream from each computer) • **By computer and data stream** provides links to pages showing a single data stream collected from a computer • **All data streams on one page** generates a report with all data on a single page
Select time range	Set a specific or sliding time range for data included in your report.
Report Settings	
Include parameter help table?	Select **yes** to include a table in the report that lists parameter settings for the report script. The default is yes.
Include table?	Select **yes** to include a table of data stream values in the report. The default is yes.
Include chart?	Select **yes** to include a chart of data stream values in the report. The default is yes.
Select chart style	Define the graphic properties of the charts in your report.
Select output folder	Set properties for the output folder.

Parameter	How to Set It
Add job ID to output folder name?	Select **yes** to append the job ID to the name of the output folder. A job ID is helpful to make the correlation between a specific instance of a Report Script and the corresponding report. The default is no.
Select properties	Set miscellaneous report properties as needed.
Add timestamp to title?	Select **yes** to append a timestamp to the title of the report, making each title unique. The timestamp is made up of the date and time the report was generated. Adding a timestamp is useful in order to run consecutive iterations of the same report without overwriting previous output. The default is no.
Event Notification	
Raise event when report succeeds?	Select **yes** to raise an event when the report is successfully generated. The default is yes.
Event severity for report success	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report is successfully generated. The default is 35.
Event severity for report with no data	Set the severity level, from 1 to 40, to indicate the importance of an event in which the generated report contains no data. The default is 25.
Event severity for report failure	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report cannot be generated. The default is 5.

15.12 Report_ServerMessageSummary

Use this Knowledge Script to generate a summary of total message traffic on a BlackBerry Enterprise Server during a monitoring interval, including the number of sent, received, and filtered messages.

This report uses data collected by the ServerActivity Knowledge Script.

NOTE: Note You may see a gap in data points if this report is run on a BlackBerry Enterprise Server on which the failover status changes from STANDBY to PRIMARY.

15.12.1 Resource Object

Report agent

15.12.2 Default Schedule

The default schedule is **Run once**.

15.12.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Data Source	
Select computer(s)	Select the computers for your report.
Select time range	Set a specific or sliding time range for data included in your report.
Select peak weekday(s)	Select the days of the week to include in your report.
Select the style	Select the style for the report: • **By computer** shows one value for each computer you selected. • **By legend** shows one value for each different legend (the legend is a truncated form of the data stream legend visible in the Operator Console). • **By computer and legend** shows one value for each unique legend from each computer.
Data Settings	

Parameter	How to Set It
Statistics to show	Select a statistical method by which to display data in the report: • **Average**: The average value of data points for the time range of the report • **Minimum**: The minimum value of data points for the time range of the report • **Maximum**: The maximum value of data points for the time range of the report • **Min**/**Avg**/**Max**: The minimum, average, and maximum values of data points for the time range of the report • **Range**: The range of values in the data stream (maximum - minimum = range) • **StandardDeviation**: The measure of how widely values are dispersed from the mean • **Sum**: The total value of data points for the time range of the report • **Close**: The last value for the time range of the report • **Change**: The difference between the first and last values for the time range of the report (close - open = change) • **Count**: The number of data points for the time range of the report
Select sorting/display option	Select whether data is sorted, or the method of display: • **No sort**: Data is not sorted • **Sort**: Data is sorted by value (lowest to highest from front to back; highest to lowest from left to right) • **Top %**: Chart only the top *N* % of selected data (sorted by default) • **Top** *N*: Chart only the top *N* of selected data (sorted by default) • **Bottom %**: Chart only the bottom *N* % of data (sorted by default) • **Bottom** *N*: Chart only the bottom *N* of selected data (sorted by default)
Percentage/count for top/bottom	Specify a number for either the percent or count defined in the previous parameter (for example, Top 10%, or Top 10). The default is 25.
Truncate top/bottom?	If set to yes, then the data table shows only the top or bottom N or % (for example, only the top 10%). Otherwise, the table shows all data. The default is no.
Show totals on the table?	If set to yes, then additional calculations are made for each column of numbers in a table, and the following values are listed at the end of the table: • **Report Average**: An average of all values in a column • **Report Minimum**: The minimum value in a column • **Report Maximum**: The maximum value in a column • **Report Total**: The total of all values in a column The default is no.
Report Settings	
Include parameter help table?	Select **yes** to include a table in the report that lists parameter settings for the report script. The default is yes.
Include table?	Select **yes** to include a table of data stream values in the report. The default is yes.
Include chart?	Select **yes** to include a chart of data stream values in the report. The default is yes.
Select chart style	Define the graphic properties of the charts in your report.

Parameter	How to Set It
Select output folder	Set properties for the output folder.
Add job ID to output folder name?	Select **yes** to append the job ID to the name of the output folder. A job ID is helpful to make the correlation between a specific instance of a Report Script and the corresponding report. The default is no.
Select properties	Set miscellaneous report properties as needed.
Add timestamp to title?	Select **yes** to append a timestamp to the title of the report, making each title unique. The timestamp is made up of the date and time the report was generated. Adding a timestamp is useful in order to run consecutive iterations of the same report without overwriting previous output. The default is no.
Event Notification	
Raise event when report succeeds?	Select **yes** to raise an event when the report is successfully generated. The default is yes.
Event severity for report success	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report is successfully generated. The default is 35.
Event severity for report with no data	Set the severity level, from 1 to 40, to indicate the importance of an event in which the generated report contains no data. The default is 25.
Event severity for report failure	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report cannot be generated. The default is 5.

15.13 Report_SRPConnectivity

Use this Knowledge Script to generate a report about the connectivity (up or down) of the BlackBerry Enterprise Server SRP connection over a specified period.

This report uses data collected by the SRPConnectionStatus Knowledge Script.

NOTE: Note You may see a gap in data points if this report is run on a BlackBerry Enterprise Server on which the failover status changes from STANDBY to PRIMARY.

15.13.1 Resource Objects

Report agent

15.13.2 Default Schedule

The default schedule is **Run once**.

15.13.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Data Source	
Select computer(s)	Select the computers for your report.
Select time range	Set a specific or sliding time range for data included in your report.
Select peak weekday(s)	Select the days of the week to include in your report.
Data Settings	
Hours or percentage on chart	Select whether to illustrate availability by hours or by percentage.
Select sorting/display option	Select whether data is sorted, or the method of display: • **No sort**: Data is not sorted • **Sort**: Data is sorted by value (lowest to highest from front to back; highest to lowest from left to right) • **Top %**: Chart only the top *N* % of selected data (sorted by default) • **Top** *N*: Chart only the top *N* of selected data (sorted by default) • **Bottom %**: Chart only the bottom *N* % of data (sorted by default) • **Bottom** *N*: Chart only the bottom *N* of selected data (sorted by default)
Percentage/count for top/bottom	Specify a number for either the percent or count defined in the previous parameter (for example, Top 10%, or Top 10). The default is 25.

Parameter	How to Set It
Truncate top/bottom?	If set to yes, the data table shows only the top or bottom N or % (for example, only the top 10%). Otherwise, the table shows all data. The default is no.
Report Settings	
Include parameter help table?	Select **yes** to include a table in the report that lists parameter settings for the report script. The default is yes.
Include table?	Select **yes** to include a table of data stream values in the report. The default is yes.
Include chart?	Select **yes** to include a chart of data stream values in the report. The default is yes.
Select chart style	Define the graphic properties of the charts in your report.
Select output folder	Set properties for the output folder.
Add job ID to output folder name?	Select **yes** to append the job ID to the name of the output folder. A job ID is helpful to make the correlation between a specific instance of a Report Script and the corresponding report. The default is no.
Select properties	Set miscellaneous report properties as needed.
Add timestamp to title?	Select **yes** to append a timestamp to the title of the report, making each title unique. The timestamp is made up of the date and time the report was generated. Adding a timestamp is useful in order to run consecutive iterations of the same report without overwriting previous output. The default is no.
Event Notification	
Raise event when report succeeds?	Select **yes** to raise an event when the report is successfully generated. The default is yes.
Event severity for report success	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report is successfully generated. The default is 35.
Event severity for report with no data	Set the severity level, from 1 to 40, to indicate the importance of an event in which the generated report contains no data. The default is 25.
Event severity for report failure	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report cannot be generated. The default is 5.

15.14 Report_UserMessageSummary

Use this Knowledge Script to generate a report about the per-user message traffic on a BlackBerry Enterprise Server during a monitoring interval, including the number of sent, received, and filtered messages per user.

This report uses data collected by the UserActivity Knowledge Script.

NOTE: Note You may see a gap in data points if this report is run on a BlackBerry Enterprise Server on which the failover status changes from STANDBY to PRIMARY.

15.14.1 Resource Object

Report agent

15.14.2 Default Schedule

The default schedule is **Run once**.

15.14.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Data Source	
Select computer(s)	Select the computers for your report.
Select time range	Set a specific or sliding time range for data included in your report.
Select peak weekday(s)	Select the days of the week to include in your report.
Select the style	Select the style for the report: • **By computer** shows one value for each computer you selected. • **By legend** shows one value for each different legend (the legend is a truncated form of the data stream legend visible in the Operator Console). • **By computer and legend** shows one value for each unique legend from each computer.
Data Settings	

Parameter	How to Set It
Statistics to show	Select a statistical method by which to display data in the report: • **Average**: The average value of data points for the time range of the report • **Minimum**: The minimum value of data points for the time range of the report • **Maximum**: The maximum value of data points for the time range of the report • **Min**/**Avg**/**Max**: The minimum, average, and maximum values of data points for the time range of the report • **Range**: The range of values in the data stream (maximum - minimum = range) • **StandardDeviation**: The measure of how widely values are dispersed from the mean • **Sum**: The total value of data points for the time range of the report • **Close**: The last value for the time range of the report • **Change**: The difference between the first and last values for the time range of the report (close - open = change) • **Count**: The number of data points for the time range of the report
Select sorting/display option	Select whether data is sorted, or the method of display: • **No sort**: Data is not sorted • **Sort**: Data is sorted by value (lowest to highest from front to back; highest to lowest from left to right) • **Top %**: Chart only the top *N* % of selected data (sorted by default) • **Top** *N*: Chart only the top *N* of selected data (sorted by default) • **Bottom %**: Chart only the bottom *N* % of data (sorted by default) • **Bottom** *N*: Chart only the bottom *N* of selected data (sorted by default)
Percentage/count for top/bottom	Specify a number for either the percent or count defined in the previous parameter (for example, Top 10%, or Top 10). The default is 25.
Truncate top/bottom?	If set to yes, then the data table shows only the top or bottom N or % (for example, only the top 10%). Otherwise, the table shows all data. The default is no.
Show totals on the table?	If set to yes, then additional calculations are made for each column of numbers in a table, and the following values are listed at the end of the table: • **Report Average**: An average of all values in a column • **Report Minimum**: The minimum value in a column • **Report Maximum**: The maximum value in a column • **Report Total**: The total of all values in a column The default is no.
Report Settings	
Include parameter help table?	Select **yes** to include a table in the report that lists parameter settings for the report script. The default is yes.
Include table?	Select **yes** to include a table of data stream values in the report. The default is yes.
Include chart?	Select **yes** to include a chart of data stream values in the report. The default is yes.
Select chart style	Define the graphic properties of the charts in your report.

Parameter	How to Set It
Select output folder	Set properties for the output folder.
Add job ID to output folder name?	Select **yes** to append the job ID to the name of the output folder. A job ID is helpful to make the correlation between a specific instance of a Report Script and the corresponding report. The default is no.
Select properties	Set miscellaneous report properties as needed.
Add timestamp to title?	Select **yes** to append a timestamp to the title of the report, making each title unique. The timestamp is made up of the date and time the report was generated. Adding a timestamp is useful in order to run consecutive iterations of the same report without overwriting previous output. The default is no.
Event Notification	
Raise event when report succeeds?	Select **yes** to raise an event when the report is successfully generated. The default is yes.
Event severity for report success	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report is successfully generated. The default is 35.
Event severity for report with no data	Set the severity level, from 1 to 40, to indicate the importance of an event in which the generated report contains no data. The default is 25.
Event severity for report failure	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report cannot be generated. The default is 5.

15.15 ResponseTime

Use this Knowledge Script to measure the round-trip response time of an e-mail message sent to a BlackBerry handheld device and a response received from the handheld device. Response time is measured using a pair of script iterations. The first time this script runs, the AppManager agent on the selected computer sends a test e-mail message from the mailbox specified in the *Sender Mailbox* parameter to the handheld device by way of the Exchange Server specified in the *Sender Mail Server* parameter.

The test message includes an instruction to the handheld device to send an automated reply. On the second script iteration, the agent checks for the reply and calculates the response time. The BlackBerry Enterprise Server places a timestamp on the message on its way to the handheld device and a timestamp on the reply sent from the handheld device. The agent uses these timestamps to calculate the response time.

This script raises an event if response time exceeds the threshold you set, or if connectivity to the handheld device has been lost.

NOTE: This script currently is not supported for use with BES 10 and later.

15.15.1 Prerequisites

The Exchange server specified in the *Sender Mail Server* parameter must have a BES profile on the BES server. In addition, the Exchange server must be associated with a MAPI profile in order to log on and to enable this script to send e-mail to the user account. If the Exchange server has a BES profile, you can run the following utility from the `\AppManager\bin\BES` directory to create the MAPI profile:

```
prof.exe –s Exchangeservername –m usermailboxname –NOTM –p MAPIprofilename –registry
```

15.15.2 Resource Object

BlackBerry Server

15.15.3 Default Schedule

The default interval is **Every 30 minutes**.

15.15.4 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Job Failure Notification	
Event severity when job fails	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the ResponseTime job fails. The default is 5.

Parameter	How to Set It
Sender Mailbox (originates test message)	Provide the name of the Exchange mailbox from which the test e-mail message should be sent to the handheld device.
Sender Mail Server (sends test message to handheld)	Provide the name of the Exchange mail server through which the e-mail message should be sent.
SMTP e-mail address of handheld (receives test message)	Provide the e-mail address of the handheld device that will receive the test message through SMTP and reply to it.
Delete inactive test messages from Sender's Inbox?	Select **Yes** to remove old test messages used for previous iterations of this job. A test message can become inactive if it will no longer be used to calculate the response time. This may occur if the response time to the handheld device is greater than the job interval length.
Monitor round-trip response time	
Event Notification	
Raise event if round-trip response time exceeds threshold?	Select **Yes** to raise an event if the time taken for the e-mail message to be sent and for a response to be received exceeds the threshold you set. The default is Yes.
Threshold – Maximum round-trip response time	Specify the maximum number of seconds allowed for the e-mail message to be sent and for a response to be received before an event is raised. Enter a value from 0 to 32000 seconds. The default is 180 seconds.
Event severity when round-trip response time exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which response time exceeds the threshold you set. The default is 5.
Data Collection	
Collect data for round-trip response time?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the round-trip response time for the e-mail message. The default is unselected.
Monitor handheld connectivity	
Event Notification	
Raise event if handheld connectivity is down?	Select **Yes** to raise an event if connectivity of the handheld device is down. The default is Yes.
Event severity when handheld connectivity is down	Set the event severity level, from 1 to 40, to indicate the importance of an event in which connectivity to the handheld device is lost. The default is 5.
Data Collection	
Collect data for handheld connectivity?	Select **Yes** to collect data for charts and reports. If enabled, returns the up or down status of the handheld device. Returns either: • **0** – handheld device is down, or • **100** – handheld device is up. The default is unselected.

15.16 ServerActivity

Use this Knowledge Script to monitor activity on a BlackBerry server. This script monitors the number of messages forwarded to handheld devices, received from handheld devices, pending, expired, non-deliverable due to error, and filtered by the server during a monitoring interval. This script also monitors the total number of messages processed during the interval: the sum of the messages forwarded to handheld devices, sent from handheld devices, and filtered.

NOTE: This script currently is not supported for use with BES 10 and later.

15.16.1 Resource Object

BlackBerry Server

15.16.2 Default Schedule

The default interval is **Every 15 minutes**.

15.16.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Job Failure Notification	
Event severity when job fails	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the ServerActivity job fails. The default is 5.
Database login	To use SQL authentication, supply login information to access the BlackBerry Enterprise Server database. If left blank, Windows authentication is used. **NOTE:** This information must already be configured in AppManager Security Manager.
Mirror database login	To use SQL authentication in a mirrored database environment, supply login information to access the BlackBerry Enterprise Server secondary database. If left blank, Windows authentication is used. **NOTE:** This information must already be configured in AppManager Security Manager.
Blackberry High Availability Notification	
Raise event when BlackBerry STANDBY mode detected?	Select Yes to raise an event when the BlackBerry Enterprise Server is in STANDBY mode. The default is unselected.
Event severity when BlackBerry STANDBY mode detected	Set the severity level from 1 to 40 to indicate the importance of an event in which the BlackBerry Enterprise Server is in STANDBY mode. The default is 15.
Raise event when BlackBerry STANDBY mode changed to PRIMARY mode?	Select **Yes** to raise an event when the BlackBerry Enterprise Server mode has changed from STANDBY to PRIMARY. The default is Yes.

Parameter	How to Set It
Event severity when BlackBerry mode changed to PRIMARY mode.	Set the severity level from 1 to 40 to indicate the importance of an event in which the BlackBerry Enterprise Server mode has changed to PRIMARY. The default is 15.
Monitor number of messages forwarded to handhelds	
Event Notification	
Raise event if number of messages forwarded to handhelds exceeds threshold?	Select **Yes** to raise an event if the number of messages forwarded to handheld devices exceeds the threshold you set. The default is Yes.
Threshold – Maximum number of messages forwarded to handhelds	Specify the maximum number of messages that can have been forwarded to handheld devices by the monitored server before an event is raised. The default is 10 messages.
Event severity when number of messages forwarded to handhelds exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of forwarded messages exceeds the threshold. The default is 5.
Data Collection	
Collect data for number of messages forwarded to handhelds?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the number of messages forwarded to handheld devices by the BlackBerry server. The default is unselected.
Monitor number of messages sent from handhelds	
Event Notification	
Raise event if number of messages sent from handhelds exceeds threshold?	Select **Yes** to raise an event if the number of messages sent from handheld device exceeds the threshold you set. The default is Yes.
Threshold – Maximum number of messages sent from handhelds	Specify the maximum number of messages that can have been sent from handheld devices to the BlackBerry server before an event is raised. The default is 10 messages.
Event severity when number of messages sent from handhelds exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of sent messages exceeds the threshold you set. The default is 5.
Data Collection	
Collect data for number of messages sent from handhelds?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the number of messages sent from handheld devices to the BlackBerry server. The default is unselected.
Monitor number of messages pending to handhelds	
Event Notification	
Raise event if number of messages pending to handhelds exceeds threshold?	Select **Yes** to raise an event if the number of messages to handheld devices that are pending during the monitoring interval exceeds the threshold you set. The default is Yes.
Threshold – Maximum number of messages pending to handhelds	Specify the maximum number of messages to handheld devices that can be pending before an event is raised. The default is 5 messages.

Parameter	How to Set It
Event severity when number of messages pending to handhelds exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of pending messages exceeds the threshold you set. The default is 5.
Data Collection	
Collect data for to number of messages pending to handhelds?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the total number of messages pending to handheld devices associated with the monitored server. The default is unselected.
Monitor number of expired messages	
Event Notification	
Raise event if number of expired messages exceeds threshold?	Select **Yes** to raise an event if the number of expired messages exceeds the threshold you set. The default is Yes.
Threshold – Maximum number of expired messages	Specify the maximum number of expired messages that can be found on the monitored BlackBerry server before an event is raised. The default is 10 messages.
Event severity when number of expired messages exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of expired messages exceeds the threshold you set. The default is 5.
Data Collection	
Collect data for number of expired messages?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the number of expired messages on the BlackBerry server. The default is unselected.
Monitor number of non-deliverable messages	
Event Notification	
Raise event if number of non-deliverable messages exceeds threshold?	Select **Yes** to raise an event if the number of non-deliverable messages queued at the BlackBerry server exceeds the threshold you set. The default is Yes.
Threshold – Maximum number of non-deliverable messages	Specify the maximum number of non-deliverable messages that can be queued at the BlackBerry server before an event is raised. The default is 5 non-deliverable messages.
Event severity when number of non-deliverable messages exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of non-deliverable messages queued at the BlackBerry server exceeds the threshold you set. The default is 5.
Data Collection	
Collect data for number of non-deliverable messages?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the total number of non-deliverable messages queued at the BlackBerry server. The default is unselected.
Monitor number of filtered messages	
Event Notification	
Raise event if number of filtered messages exceeds threshold?	Select **Yes** to raise an event if the number of messages refused by the BlackBerry server exceeds the threshold you set. The default is Yes.
Threshold – Maximum number of filtered messages	Specify the maximum number of messages that can be refused by the BlackBerry server before an event is raised. The default is 10 filtered messages.

Parameter	How to Set It
Event severity when number of filtered messages exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of refused messages exceeds the threshold you set. The default is 5.
Data Collection	
Collect data for number of filtered messages?	Select **Yes** to collect data for charts and reports. If enabled, returns the total number of messages refused by the BlackBerry server. The default is unselected.
Monitor total number of messages processed	
Event Notification	
Raise event if total number of messages processed exceeds threshold?	Select **Yes** to raise an event if the total number of messages processed by the BlackBerry server exceeds the threshold you set. The default is Yes.
Threshold – Maximum total number of messages processed	Specify the maximum total number of messages that can be processed by the BlackBerry server during any monitoring interval before an event is raised. The default is 50 messages.
Event severity when total number of messages processed exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of processed messages exceeds the threshold you set. The default is 5.
Data Collection	
Collect data for total number of messages processed?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the total number of messages processed by the BlackBerry server during the monitoring interval. This total is the sum of the messages forwarded to handheld devices, sent from handheld devices, and filtered. The default is unselected.

15.17 ServiceHealth

Use this Knowledge Script to monitor the health of BlackBerry Enterprise Server services. This script monitors the status of services as well as the percentage of server CPU time and the amount of memory used by these services.

The following services are monitored:

- BlackBerry Alert Service
- BlackBerry Controller Service
- BlackBerry Database Consistency Service

  NOTE: The Database Consistency Service is not available in BES 5 and later.

- BlackBerry Dispatcher
- BlackBerry Mobile Data Service
  - MDS Connection Service
  - MDS Integration Service

    NOTE: The MDS Integration Service is not available in BES 5 and later.

- BlackBerry Policy Service
- BlackBerry Synchronization Service
- BlackBerry Router Service
- BlackBerry Attachment Service
- BlackBerry Administration Service - Application Server
- BlackBerry Administration Service - Native Code Container
- BlackBerry Collaboration Service
- BlackBerry Mail Store Service

This script raises an event if a service is down, or if memory or CPU utilization exceeds either of the thresholds you set.

You can set this script to automatically start a service that is down.

NOTE: The following services are not available in BES 10 and later:

- BlackBerry Alert
- BlackBerry Attachment Service
- BlackBerry Mail Store Service
- BlackBerry Policy Service
- BlackBerry Synchronization Service

15.17.1 Resource Object

BlackBerry Enterprise Server service

15.17.2 Default Schedule

The default interval is **Every 30 minutes**.

15.17.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Job Failure Notification	
Event severity when job fails	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the ServiceHealth job fails. The default is 5.
Restart service if down?	Select **Yes** to automatically restart a service that is not running. The default is unselected.
Raise event if attempt to restart service succeeds?	Select **Yes** to raise an event when AppManager successfully restarts a service that is not running. The default is Yes.
Event severity when attempt to restart service succeeds	Set the event severity level, from 1 to 40, to indicate the importance of an event in which a service is successfully restarted. The default is 25.
Raise event if attempt to restart service fails?	Select **Yes** to raise an event when AppManager cannot restart a service that is not running. The default is Yes.
Event severity when attempt to restart service fails	Set the event severity level, from 1 to 40, to indicate the importance of an event in which a service cannot be restarted. The default is 5.
Monitor service status	
Event Notification	
Raise event if service is down?	Select **Yes** to raise an event if a monitored BlackBerry Server service is not running. The default is Yes.
Event severity when service is down	Set the event severity level, from 1 to 40, to indicate the importance of an event in which a monitored service is not running. The default is 5.
Data Collection	
Collect data for service status?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the status of all instances of a BlackBerry Server service during the monitoring interval. The default is unselected.
Monitor CPU utilization	
Event Notification	
Raise event if CPU utilization exceeds threshold?	Select **Yes** to raise an event if CPU utilization by BlackBerry Server services exceeds the threshold you set. The default is Yes.
Threshold – Maximum CPU utilization for BlackBerry Administration Service - Application Server	Specify the maximum amount of CPU utilization (as a percentage of CPU time) that the BlackBerry Administration Service - Application Server can have before an event is raised. The default is 30%.

Parameter	How to Set It
Event severity when CPU utilization for BlackBerry Administration Service - Application Server exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the BlackBerry Administration Service Application Server exceeds the CPU utilization threshold. The default is 5.
Threshold – Maximum CPU utilization for BlackBerry Administration Service - Native Code Container	Specify the maximum amount of CPU utilization (as a percentage of CPU time) that the BlackBerry Administration Service - Native Code Container can have before an event is raised. The default is 30%.
Event severity when CPU utilization for BlackBerry Administration Service - Native Code Container exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the BlackBerry Administration Service Application Server - Native Code Container exceeds the CPU utilization threshold. The default is 5.
Threshold – Maximum CPU utilization for BlackBerry Alert Service	Specify the maximum amount of CPU utilization (as a percentage of CPU time) that the BlackBerry Alert Service can have before an event is raised. The default is 30%. **NOTE:** This parameter is not applicable for BES 10 and later.
Event severity when CPU utilization for BlackBerry Alert Service exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the BlackBerry Alert Service exceeds the CPU utilization threshold. The default is 5.
Threshold - Maximum CPU utilization for BlackBerry Attachment Service	Specify the maximum amount of CPU utilization (as a percentage of CPU time) that the Attachment Service can have before an event is raised. The default is 30%. **NOTE:** This parameter is not applicable for BES 10 and later.
Event severity when CPU utilization for BlackBerry Attachment Service exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the Attachment Service exceeds the CPU utilization threshold. The default is 5.
Threshold - Maximum CPU utilization for BlackBerry Collaboration Service	Specify the maximum amount of CPU utilization (as a percentage of CPU time) that the BlackBerry Collaboration Service can have before an event is raised. The default is 30%.
Event severity when CPU utilization for BlackBerry Collaboration Service exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the BlackBerry Collaboration Service exceeds the CPU utilization threshold. The default is 5.
Threshold – Maximum CPU utilization for BlackBerry Controller Service	Specify the maximum amount of CPU utilization (as a percentage of CPU time) that the BlackBerry Controller Service can have before an event is raised. The default is 30%.
Event severity when CPU utilization for BlackBerry Controller Service exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the BlackBerry Controller Server exceeds the CPU utilization threshold. The default is 5.

Parameter	How to Set It
Threshold – Maximum CPU utilization for BlackBerry Database Consistency Service	Specify the maximum amount of CPU utilization (as a percentage of CPU time) that the BlackBerry Database Consistency Service can have before an event is raised. The default is 30%. **NOTE:** This parameter is not applicable for BES 5 and later.
Event severity when CPU utilization for BlackBerry Database Consistency Service exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the BlackBerry Database Consistency Service exceeds the CPU utilization threshold. The default is 5.
Threshold – Maximum CPU utilization for BlackBerry Dispatcher Service	Specify the maximum amount of CPU utilization (as a percentage of CPU time) that the BlackBerry Dispatcher Service can have before an event is raised. The default is 30%.
Event severity when CPU utilization for BlackBerry Dispatcher Service exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the BlackBerry Dispatcher Service exceeds the CPU utilization threshold. The default is 5.
Threshold – Maximum CPU utilization for BlackBerry MailStore Service	Specify the maximum amount of CPU utilization (as a percentage of CPU time) that the BlackBerry MailStore Service can have before an event is raised. The default is 30%. **NOTE:** This parameter is not applicable for BES 10 and later.
Event severity when CPU utilization for BlackBerry MailStore Service exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the BlackBerry MailStore Service exceeds the CPU utilization threshold. The default is 5.
Threshold – Maximum CPU utilization for BlackBerry Mobile Data Service	Specify the maximum amount of CPU utilization (as a percentage of CPU time) that the BlackBerry Mobile Data Service can have before an event is raised. The default is 30%.
Event severity when CPU utilization for BlackBerry Mobile Data Service exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the BlackBerry Mobile Data Service exceeds the CPU utilization threshold. The default is 5.
Threshold – Maximum CPU utilization for BlackBerry Policy Service	Specify the maximum amount of CPU utilization (as a percentage of CPU time) that the BlackBerry Policy Service can have before an event is raised. The default is 30%. **NOTE:** This parameter is not applicable for BES 10 and later.
Event severity when CPU utilization for BlackBerry Policy Service exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the BlackBerry Policy Service exceeds the CPU utilization threshold. The default is 5.
Threshold – Maximum CPU utilization for BlackBerry Router Service	Specify the maximum amount of CPU utilization (as a percentage of CPU time) that the BlackBerry Router Service can have before an event is raised. The default is 30%.
Event severity when CPU utilization for BlackBerry Router Service exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the BlackBerry Router Service exceeds the CPU utilization threshold. The default is 5.

Parameter	How to Set It
Threshold – Maximum CPU utilization for BlackBerry Synchronization Service	Specify the maximum amount of CPU utilization (as a percentage of CPU time) that the BlackBerry Synchronization Service can have before an event is raised. The default is 30%. **NOTE:** This parameter is not applicable for BES 10 and later.
Event severity when CPU utilization for BlackBerry Synchronization Service exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the BlackBerry Synchronization Service exceeds the CPU utilization threshold. The default is 5.
Data Collection	
Collect data for CPU utilization?	Select **Yes** to collect data for charts and reports. If enabled, returns the percentage of CPU time used by BlackBerry Enterprise Server services during the monitoring interval. The default is unselected.
Monitor memory utilization	
Event Notification	
Raise event if memory utilization exceeds threshold?	Select **Yes** to raise an event if the memory utilization by BlackBerry server services exceeds the threshold you set. The default is Yes.
Threshold – Maximum memory utilization for BlackBerry Administration Service - Application Server	Specify the maximum amount of memory that the BlackBerry Administration Service - Application Server can use before an event is raised. The default is 8192 Kilobytes.
Event severity when memory utilization for BlackBerry Administration Service - Application Server exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the BlackBerry Administration Service - Application Server exceeds the memory utilization threshold. The default is 5.
Threshold – Maximum memory utilization for BlackBerry Administration Service - Native Code Container	Specify the maximum amount of memory that the BlackBerry Administration Service - Native Code Container can use before an event is raised. The default is 8192 Kilobytes.
Event severity when memory utilization for BlackBerry Administration Service - Native Code Container exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the BlackBerry Administration Service - Native Code Container exceeds the memory utilization threshold. The default is 5.
Threshold – Maximum memory utilization for BlackBerry Alert Service	Specify the maximum amount of memory that the BlackBerry Alert Service can use before an event is raised. The default is 8192 Kilobytes. **NOTE:** This parameter is not applicable for BES 10 and later.
Event severity when memory utilization for BlackBerry Alert Service exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the BlackBerry Alert Service exceeds the memory utilization threshold. The default is 5.

Parameter	How to Set It
Threshold – Maximum memory utilization for BlackBerry Attachment Service	Specify the maximum amount of memory that the BlackBerry Attachment Service can use before an event is raised. The default is 8192 Kilobytes. **NOTE:** This parameter is not applicable for BES 10 and later.
Event severity when memory utilization for BlackBerry Attachment Service exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the BlackBerry Attachment Service exceeds the memory utilization threshold. The default is 5.
Threshold – Maximum memory utilization for BlackBerry Collaboration Service	Specify the maximum amount of memory that the BlackBerry Collaboration Service can use before an event is raised. The default is 8192 Kilobytes.
Event severity when memory utilization for BlackBerry Collaboration Service exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the BlackBerry Collaboration Service exceeds the memory utilization threshold. The default is 5.
Threshold – Maximum memory utilization for BlackBerry Controller Service	Specify the maximum amount of memory that the BlackBerry Controller Service can use before an event is raised. The default is 8192 Kilobytes.
Event severity when memory utilization for BlackBerry Controller Service exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the BlackBerry Controller Service exceeds the memory utilization threshold. The default is 5.
Threshold – Maximum memory utilization for BlackBerry Database Consistency Service	Specify the maximum amount of memory that the BlackBerry Database Consistency Service can use before an event is raised. The default is 8192 Kilobytes. **NOTE:** This parameter is not applicable for BES 5 and later.
Event severity when memory utilization for BlackBerry Database Consistency Service exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the BlackBerry Database Consistency Service exceeds the memory utilization threshold. The default is 5.
Threshold – Maximum memory utilization for BlackBerry Dispatcher Service	Specify the maximum amount of memory that the BlackBerry Dispatcher Service can use before an event is raised. The default is 8192 Kilobytes.
Event severity when memory utilization for BlackBerry Dispatcher Service exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the BlackBerry Dispatcher Service exceeds the memory utilization threshold. The default is 5.
Threshold – Maximum memory utilization for BlackBerry MailStore Service	Specify the maximum amount of memory that the BlackBerry MailStore Service can use before an event is raised. The default is 8192 Kilobytes. **NOTE:** This parameter is not applicable for BES 10 and later.

Parameter	How to Set It
Event severity when memory utilization for BlackBerry MailStore Service exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the BlackBerry MailStore Service exceeds the memory utilization threshold. The default is 5.
Threshold – Maximum memory utilization for BlackBerry Mobile Data Service	Specify the maximum amount of memory that the BlackBerry Mobile Data Service can use before an event is raised. The default is 8192 Kilobytes.
Event severity when memory utilization for BlackBerry Mobile Data Service exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the BlackBerry Mobile Data Service exceeds the memory utilization threshold. The default is 5.
Threshold – Maximum memory utilization for BlackBerry Policy Service	Specify the maximum amount of memory that the BlackBerry Policy Service can use before an event is raised. The default is 8192 Kilobytes. **NOTE:** This parameter is not applicable for BES 10 and later.
Event severity when memory utilization for BlackBerry Policy Service exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the BlackBerry Policy Service exceeds the memory utilization threshold. The default is 5.
Threshold – Maximum memory utilization for BlackBerry Router Service	Specify the maximum amount of memory that the BlackBerry Router Service can use before an event is raised. The default is 8192 Kilobytes.
Event severity when memory utilization for BlackBerry Router Service exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the BlackBerry Router Service exceeds the memory utilization threshold. The default is 5.
Threshold – Maximum memory utilization for BlackBerry Synchronization Service	Specify the maximum amount of memory that the BlackBerry Synchronization Service can use before an event is raised. The default is 8192 Kilobytes. **NOTE:** This parameter is not applicable for BES 10 and later.
Event severity when memory utilization for BlackBerry Synchronization Service exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the BlackBerry Synchronization Service exceeds the memory utilization threshold. The default is 5.
Data Collection	
Collect data for memory utilization?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the amount of memory used by BlackBerry Enterprise Server services during the monitoring interval. The default is unselected.

15.18 SRPConnectionStatus

Use this Knowledge Script to monitor the status of the Server Routing Protocol (SRP) connection between the BlackBerry server and the Research in Motion (RIM) infrastructure.

SRP makes a TCP/IP connection to the wireless network to transmit e-mail messages to and from your wireless ISP. SRP is built on top of a TCP session between Port 3101 of the BlackBerry Enterprise Server and the IP address `srp.blackberry.net` or `srp.na.blackberry.net`.

This script raises an event when the SRP connection is down, and when thresholds are exceeded for the number of failed attempts to reconnect to the wireless network or for the number of seconds the SRP connection can be down during a monitoring interval.

15.18.1 Resource Object

BlackBerry Server

15.18.2 Default Schedule

The default interval is **Every 5 minutes**.

15.18.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Job Failure Notification	
Event severity when job fails	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the SRPConnectionStatus job fails. The default is 5.
Raise event if last SRP connection error occurred during last monitoring interval?	Select **Yes** to raise an event if the last SRP connection error that this Knowledge Script detected occurred during the most recent monitoring interval. The default is Yes.
Event severity when last SRP connection error occurred during last monitoring interval	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the last SRP connection error occurred during the most recent monitoring interval. The default is 5.
Blackberry High Availability Notification	
Raise event when BlackBerry STANDBY mode detected?	Select Yes to raise an event when the BlackBerry Enterprise Server is in STANDBY mode. The default is unselected.
Event severity when BlackBerry STANDBY mode detected	Set the severity level from 1 to 40 to indicate the importance of an event in which the BlackBerry Enterprise Server is in STANDBY mode. The default is 15.

Parameter	How to Set It
Raise event when BlackBerry STANDBY mode changed to PRIMARY mode?	Select **Yes** to raise an event when the BlackBerry Enterprise Server mode has changed from STANDBY to PRIMARY. The default is Yes.
Event severity when BlackBerry mode changed to PRIMARY mode.	Set the severity level from 1 to 40 to indicate the importance of an event in which the BlackBerry Enterprise Server mode has changed to PRIMARY. The default is 15.
Monitor SRP connection status	
Event Notification	
Raise event if SRP connection is down?	Select **Yes** to raise an event if the SRP connection to the RIM wireless network is down. The default is Yes.
Event severity when SRP connection is down	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the SRP connection is down. The default is 5.
Data Collection	
Collect data for SRP connection status?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the status of the SRP connection to the wireless network, either: • 0 – SRP connection is down, or • 100 – SRP connection is up. The default is unselected.
Monitor number of failed SRP reconnects	
Event Notification	
Raise event if number of failed SRP reconnects exceeds threshold?	Select **Yes** to raise an event if the number of failed attempts to re-establish the SRP connection exceeds the threshold you set. The default is Yes.
Threshold – Maximum number of failed SRP reconnects	Specify the maximum number of times that an attempt to re-establish a lost SRP connection to the wireless network can fail before an event is raised. The default is 2 times.
Event severity when number of failed SRP reconnects exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event if the number of attempts to re-establish a connection exceeds the threshold you set. The default is 5.
Data Collection	
Collect data for number of failed SRP reconnects?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the number of times that an attempt to re-establish a lost SRP connection to the wireless network failed during the monitoring interval. The default is unselected.
Monitor number of seconds not connected to wireless network	
Event Notification	
Raise event if number of seconds not connected to wireless network exceeds threshold?	Select **Yes** to raise an event if the number of seconds that the SRP connection to the RIM wireless network was down exceeds the threshold you set. The default is Yes.

Parameter	How to Set It
Threshold – Maximum number of seconds not connected to wireless network	Specify the maximum number of seconds that the BlackBerry Enterprise Server was not connected to the wireless network because the SRP connection was down. If the threshold is exceeded, an event is raised. The default is 30 seconds.
Event severity when number of seconds not connected to wireless network exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event if the length of time the BlackBerry Enterprise Server was down exceeds the threshold you set. The default is 5.
Data Collection	
Collect data for number of seconds not connected to wireless network?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the amount of time, in seconds, that the SRP connection to the RIM wireless network was down during the monitoring interval. The default is unselected.

15.19 SRPTest

Use this Knowledge Script to perform a Ping test of the Server Routing Protocol (SRP) connection between the BlackBerry server and the Research In Motion (RIM) wireless network.

SRP makes a TCP/IP connection to the wireless network to transmit e-mail messages to and from the wireless ISP. SRP is built on top of a TCP session between the BlackBerry Enterprise Server and an IP address.

An event is raised when the BlackBerry server SRP connection returns a non-zero exit code (meaning that a connection could not be established). The script can also raise an event if the Ping test is successful.

NOTE:

- You should run this Knowledge Script only on Blackberry server.
- This script requires the BBSRPTest utility to run. If it is not installed in the default location, you need to supply a full path to its location.

15.19.1 Resource Object

BlackBerry Enterprise Server

15.19.2 Default Schedule

The default schedule is **Run once**.

15.19.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Job Failure Notification	
Event severity when job fails	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the SRPTest job fails. The default is 5.
Database login	To use SQL authentication, supply login information to access the BlackBerry Enterprise Server database. If left blank, Windows authentication is used. **NOTE:** SQL authentication information must already be configured in AppManager Security Manager.
Mirror database login	To use SQL authentication in a mirrored database environment, supply login information to access the BlackBerry Enterprise Server secondary database. If left blank, Windows authentication is used. **NOTE:** This information must already be configured in AppManager Security Manager.
Path and filename for BBSRPTest utility	Provide the path and filename for the BlackBerry utility required to run the Ping test. Leave blank to use the BlackBerry default path.

Parameter	How to Set It
BBSRPTest utility timeout	Set a timeout value from 1 to 120 seconds. The script tries to locate the `BBSRPTest` utility (required to run the Ping test) until the timeout expires. The default is 20 seconds.
Raise event if Ping test succeeds?	Select **Yes** to raise an event if the Ping test to the BlackBerry server SRP connection is successful. The default is Yes.
Event severity when Ping test succeeds	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the Ping test was successful. The default is 25.
Raise event if Ping test fails?	Select **Yes** to raise an event if the Ping test to the BlackBerry server SRP connection returns a non-zero exit code. The default is Yes.
Event severity when Ping test fails	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the Ping test returns a non-zero exit code. The default is 5.
Monitor SRP Ping status	
Data Collection	
Collect data for SRP Ping status?	Select **Yes** to collect data for charts and reports. If enabled, returns the following: • 100 – SRP Ping test was successful • 0 – SRP Ping test failed. The default is unselected.

15.20 UserActivity

Use this Knowledge Script to monitor the activity of each user on a BlackBerry server. This script monitors, on a per-user basis, the number of messages forwarded to handheld devices, received from handheld devices, pending, expired, non-deliverable due to error, and filtered by the server during a monitoring interval. This script also monitors the total number of messages processed during the interval.

This script raises an event if a metric exceeds one of the thresholds you set.

If you have supplied a valid filename for the *File with list of users to monitor* parameter and you make any changes to that file, the changes will not take effect for that job. Nor can you start and stop the running job for the changes to take effect. You must instead create a new job using the modified file, because the file is read only when the UserActivity job is created. The values in the file are not updated until a new job is created.

NOTE: This script currently is not supported for use with BES 10 and later.

15.20.1 Resource Object

BlackBerry Server

15.20.2 Default Schedule

The default schedule is **Every hour**.

15.20.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Job Failure Notification	
Event severity when job fails	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the UserActivity job fails. The default is 5.
Database login	To use SQL authentication, supply login information to access the BlackBerry Enterprise Server database. If left blank, Windows authentication is used. **NOTE:** SQL authentication information must already be configured in AppManager Security Manager.
Mirror database login	To use SQL authentication in a mirrored database environment, supply login information to access the BlackBerry Enterprise Server secondary database. If left blank, Windows authentication is used. **NOTE:** This information must already be configured in AppManager Security Manager.

Parameter	How to Set It
Maximum number of users to record data streams for	Specify the maximum number of users to include when collecting data. When data collection is enabled, this script returns per-user statistics for each user on the server. This parameter sets an upper limit on the number of users for whom such data should be collected and returned. The default is 50 users.
File with list of users to monitor	Click **Browse** (...) to locate a file containing a list of the users you want to monitor with this script. The file should contain a list of the user names associated with the email accounts whose results you want to include in the event details. Separate each user name with a pipe (|).
Blackberry High Availability Notification	
Raise event when BlackBerry STANDBY mode detected?	Select Yes to raise an event when the BlackBerry Enterprise Server is in STANDBY mode. The default is unselected.
Event severity when BlackBerry STANDBY mode detected	Set the severity level from 1 to 40 to indicate the importance of an event in which the BlackBerry Enterprise Server is in STANDBY mode. The default is 15.
Raise event when BlackBerry STANDBY mode changed to PRIMARY mode?	Select **Yes** to raise an event when the BlackBerry Enterprise Server mode has changed from STANDBY to PRIMARY. The default is Yes.
Event severity when BlackBerry mode changed to PRIMARY mode.	Set the severity level from 1 to 40 to indicate the importance of an event in which the BlackBerry Enterprise Server mode has changed to PRIMARY. The default is 15.
Monitor number of messages forwarded to handheld	
Event Notification	
Raise event if number of messages forwarded to handheld exceeds threshold?	Select **Yes** to raise an event if the number of messages forwarded to any handheld device by the monitored server exceeds the threshold you set. The default is Yes.
Threshold – Maximum number of messages forwarded to handheld	Specify the maximum number of messages that can be forwarded to any handheld device by the monitored server before an event is raised. The default is 10 messages.
Event severity when number of messages forwarded to handheld exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of forwarded messages exceeds the threshold you set. The default is 5.
Data Collection	
Collect data for number of messages forwarded to handheld?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the number of messages forwarded to each handheld device by the monitored server. The default is unselected.
Monitor number of messages sent from handheld	
Event Notification	
Raise event if number of messages sent from handheld exceeds threshold?	Select **Yes** to raise an event if the number of messages sent from any handheld device exceeds the threshold you set. The default is Yes.
Threshold – Maximum number of messages sent from handheld	Specify the maximum number of messages that can be sent from a handheld device to the BlackBerry Enterprise Server before an event is raised. The default is 10 messages.

Parameter	How to Set It
Event severity when number of messages sent from handheld exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of sent messages exceeds the threshold you set. The default is 5.
Data Collection	
Collect data for number of messages sent from handheld?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the number of messages sent from each handheld device to the BlackBerry Enterprise Server. The default is unselected.
Monitor number of messages pending to handheld	
Event Notification	
Raise event if number of messages pending to handheld exceeds threshold?	Select **Yes** to raise an event if the number of messages to any handheld device that are pending during the monitoring interval exceeds the threshold you set. The default is Yes.
Threshold – Maximum number of messages pending to handheld	Specify the maximum number of messages to any handheld device that can be pending before an event is raised. The default is 5 messages.
Event severity when number of messages pending to handheld exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of pending messages exceeds the threshold you set. The default is 5.
Data Collection	
Collect data for to number of messages pending to handheld?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the total number of messages pending to each handheld device associated with the monitored server. The default is unselected.
Monitor number of expired messages	
Event Notification	
Raise event if number of expired messages exceeds threshold?	Select **Yes** to raise an event if the number of expired messages for any user exceeds the threshold you set. The default is Yes.
Threshold – Maximum number of expired messages	Specify the maximum number of expired messages for any user that can be found on the monitored server before an event is raised. The default is 10 messages.
Event severity when number of expired messages exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of expired messages exceeds the threshold. The default is 5.
Data Collection	
Collect data for number of expired messages?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the number of expired messages for each user on the monitored server. The default is unselected.
Monitor number of non-deliverable messages	
Event Notification	
Raise event if number of non-deliverable messages exceeds threshold?	Select **Yes** to raise an event if the number of undeliverable messages for any user on the monitored server exceeds the threshold you set. The default is Yes.
Threshold – Maximum number of non-deliverable messages	Specify the maximum number of undeliverable messages that can be found for any user on the BlackBerry Enterprise Server before an event is raised. The default is 5 undeliverable messages.

Parameter	How to Set It
Event severity when number of non-deliverable messages exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of undeliverable messages exceeds the threshold you set. The default is 5.
Data Collection	
Collect data for number of non-deliverable messages?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the total number of undeliverable messages per user on the monitored server. The default is unselected.
Monitor number of filtered messages	
Event Notification	
Raise event if number of filtered messages exceeds threshold?	Select **Yes** to raise an event if the number of messages for a user that were refused by the monitored server exceeds the threshold you set. The default is Yes.
Threshold – Maximum number of filtered messages	Specify the maximum number of messages for any user that can be refused by the monitored server before an event is raised. The default is 10 filtered messages.
Event severity when number of filtered messages exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of refused messages exceeds the threshold you set. the default is 5.
Data Collection	
Collect data for number of filtered messages?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the number of messages for each user that were refused by the monitored server. The default is unselected.
Monitor total number of messages processed	
Event Notification	
Raise event if total number of messages processed exceeds threshold?	Select **Yes** to raise an event if the number of messages for any user that can be processed by the monitored server exceeds the threshold you set. The default is Yes.
Threshold – Maximum total number of messages processed	Specify the maximum number of messages for any user that can be processed by the monitored server during any monitoring interval before an event is raised. The default is 50 messages.
Event severity when total number of messages processed exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of processed messages exceeds the threshold you set. The default is 5.
Data Collection	
Collect data for total number of messages processed?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the total number of messages for each user that were processed by the BlackBerry Enterprise Server during the monitoring interval. This total is the sum of the messages forwarded to handheld devices, sent from handheld devices, and filtered, on a per-user basis. The default is unselected.

15.21 UserCount

Use this Knowledge Script to report the total number of user connections and the percentage of licenses in use on your Blackberry environment.

15.21.1 Resource Object

BlackBerry Server

15.21.2 Default Schedule

The default schedule is **Every 24 hours**.

15.21.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Job Failure Notification	
Event severity when job fails	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the UserCount job fails. The default is 5.
Blackberry High Availability Notification	
Raise event when BlackBerry STANDBY mode detected?	Select Yes to raise an event when the BlackBerry Enterprise Server is in STANDBY mode. The default is unselected.
Event severity when BlackBerry STANDBY mode detected	Set the severity level from 1 to 40 to indicate the importance of an event in which the BlackBerry Enterprise Server is in STANDBY mode. The default is 15.
Raise event when BlackBerry STANDBY mode changed to PRIMARY mode?	Select **Yes** to raise an event when the BlackBerry Enterprise Server mode has changed from STANDBY to PRIMARY. The default is Yes.
Event severity when BlackBerry mode changed to PRIMARY mode.	Set the severity level from 1 to 40 to indicate the importance of an event in which the BlackBerry Enterprise Server mode has changed to PRIMARY. The default is 15.
Monitor number of users on a BlackBerry server	
Event Notification	
Raise event if number of users on a BlackBerry server exceeds threshold?	Select **Yes** to raise an event if the number of users on your BlackBerry environment exceeds the threshold you set. The default is Yes.
Threshold – Maximum number of users on a BlackBerry server	Specify the maximum number of user connections allowed on your BlackBerry environment before an event is raised. The default is 1900 users.
Event severity when number of users on a BlackBerry server exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of users on your BlackBerry environment exceeds the threshold you set. The default is 5.

Parameter	How to Set It
Data Collection	
Collect data for number of users on a BlackBerry server?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the number of users associated with the BlackBerry environment. The default is unselected.
Monitor percentage of licenses in use	
Event Notification	
Raise event if percentage of licenses in use exceeds threshold?	Select **Yes** to raise an event if the percentage of BlackBerry Enterprise Server licenses currently in use exceeds the threshold you set. The default is Yes.
Threshold – Maximum percentage of licenses in use	Specify the maximum percentage of BlackBerry Enterprise Server licenses that can be in use before an event is raised. The default is 80%.
Event severity when percentage of licences in use exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the percentage of licenses in use exceeds the threshold. The default is 5.
Data Collection	
Collect data for percentage of licences in use?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the percentage of BlackBerry Enterprise Server licenses that are currently being used. The default is unselected.

15.22 UsersWithPendingMessages

Use this Knowledge Script to report on the percentage of all users whose handheld device accounts contain pending messages on a BlackBerry Enterprise Server. You can specify which users to monitor and can set a threshold for the maximum percentage of users with pending messages allowed on that server.

Any changes you make to the file specified in the *File with list of users to monitor* parameter while the job is running do not take effect for that job. Nor will the changes take effect if you start and stop the running job. You must instead create a new job using the modified file. Because the file is read-only when the UsersWithPendingMessages job is created, the values in the file are not updated until a new job is created.

NOTE: This script currently is not supported for use with BES 10 and later.

15.22.1 Resource Object

BlackBerry Server

15.22.2 Default Schedule

The default schedule is **Every 15 minutes**.

15.22.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Job Failure Notification	
Event severity when job fails	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the UsersWithPendingMessages job fails. The default is 5.
Database login	To use SQL authentication, supply login information to access the BlackBerry Enterprise Server database. If left blank, Windows authentication is used. **NOTE:** This information must already be configured in AppManager Security Manager.
Mirror database login	To use SQL authentication in a mirrored database environment, supply login information to access the BlackBerry Enterprise Server secondary database. If left blank, Windows authentication is used. **NOTE:** This information must already be configured in AppManager Security Manager.
File with list of users to monitor	Click **Browse** (...) to locate a file containing a list of the handheld device users you want to monitor with this script. The file should list the display names associated with the email accounts whose results you want to include in the event details. Place each display name on a separate line in the file.
Blackberry High Availability Notification	

Parameter	How to Set It
Raise event when BlackBerry STANDBY mode detected?	Select Yes to raise an event when the BlackBerry Enterprise Server is in STANDBY mode. The default is unselected.
Event severity when BlackBerry STANDBY mode detected	Set the severity level from 1 to 40 to indicate the importance of an event in which the BlackBerry Enterprise Server is in STANDBY mode. The default is 15.
Raise event when BlackBerry STANDBY mode changed to PRIMARY mode?	Select **Yes** to raise an event when the BlackBerry Enterprise Server mode has changed from STANDBY to PRIMARY. The default is Yes.
Event severity when BlackBerry mode changed to PRIMARY mode.	Set the severity level from 1 to 40 to indicate the importance of an event in which the BlackBerry Enterprise Server mode has changed to PRIMARY. The default is 15.
Monitor percentage of users with messages pending to handheld?	Select **Yes** to monitor the percentage of users on a BlackBerry server who can have messages pending and not yet sent to their handheld device. The default is Yes.
Event Notification	
Raise event if percentage of users with messages pending to handheld exceeds threshold?	Select **Yes** to raise an event if the percentage of users with messages pending and not yet sent to their handheld device exceeds the threshold you set. The default is Yes.
Threshold – Maximum percentage of users with messages pending to handheld	Specify the maximum percentage of users associated with a BlackBerry server that can have messages pending before an event is raised. The default is 15%.
Event severity when percentage of users with messages pending to handheld exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 5.
Data Collection	
Collect data for percentage of users with messages pending to handheld?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the number of users associated with the BlackBerry server. The default is unselected.

16 BlackBerry Knowledge Scripts

AppManager provides a set of Knowledge Scripts for monitoring BlackBerry servers. It also includes Knowledge Scripts to create reports about the performance of your BlackBerry Enterprise Server implementation.

NOTE: You may need to upgrade to Microsoft Windows Script version 5.6 or later to prevent the handle counts for the NetIQ AppManager Client Resource Monitor (NetIQmc) process from increasing when you run the MessagingServerList, SRPTest, UserCountByServer, or UserList Knowledge Scripts.

From the Knowledge Script view of Control Center, you can access more information about any NetIQ-supported Knowledge Script by selecting it and clicking **Help**. In the Operator Console, click any Knowledge Script in the Knowledge Script pane and press **F1** For more information about how to use the Report Knowledge Scripts, see the *Reporting Guide*.

Knowledge Script	What It Does
BesAlertForward	Sends alerts using SNMP, MAPI Mail, Notes Mail, Pager, MessageBox, or a customized method whenever an event of a specified type occurs.
DebugLogTotalSize	Calculates the total debug log size.
EventLog	Monitors and filters information in the Windows Event Log specific to the BlackBerry Enterprise Server.
ExchangeAvail	Checks Exchange Server availability and the response time for a client request to open a mailbox.
HungThreads	Monitors a BlackBerry Server service for hung (blocked) threads. Can optionally restart a service.
MessagingServerList	Lists all Exchange Servers with at least one user on the BlackBerry Enterprise Server.
MsgAvgSize	Gathers average size in bytes of messages transferred to handheld devices by a BlackBerry Server.
MsgBytesReceived	Gathers the number of message bytes transferred to a handheld device during a monitoring interval.
MsgsExpired	Monitors the number of messages that expired during the monitoring interval.
PurgeDebugLog	Monitors the total size of BlackBerry Server service debug log files and optionally deletes files that are older than a specified date.
Report_EndToEndConnectivity	Generates a report about connectivity between the Exchange and BlackBerry Enterprise Servers and a BlackBerry handheld.
Report_EndToEndResponseTime	Generates a report about email round-trip response time.

Knowledge Script	What It Does
Report_ExchangeConnectionTime	Generates a report about the response time of an Exchange Server.
Report_ExchangeConnectivity	Generates a report about connectivity with an Exchange Server.
Report_MessagesByInterval	Generates a report about the total number of messages exchanged during a monitoring interval.
Report_MessageSummary	Generates a report about the total number of new messages, including messages sent, received, filtered, and queued during the monitoring interval.
Report_ServerList	Generates a report listing the messaging (Exchange) servers used by a BlackBerry Server service.
Report_SRPConnectionUptime	Generates a report about the percentage of uptime for the connection to the wireless network.
Report_SRPConnectivity	Generates a report about the connectivity (up or down) of the BlackBerry Server SRP connection over a specified period.
Report_UserByServer	Generates a report about the number of users on an Exchange Server for a BlackBerry Server.
Report_UserListing	Generates a report about the number of users on a BlackBerry Server service. A list of users can be sorted by server association or alphabetically.
ResponseTime	Sends a message to a handheld from the BlackBerry-enabled Exchange mailbox, checks for a reply, and determines end-to-end response time.
ServerHealth	Monitors BlackBerry Enterprise Server health, the percentage of memory used, and the percentage of CPU and memory used by BlackBerry Server processes.
ServerLoad	Monitors the rate at which messages are filtered, sent, received, queued and the total new message activity during an interval.
ServicesDown	Monitors the availability of BlackBerry Enterprise Server services and optionally restarts a service.
SNMPAlertForward	Monitors and filters information in the Windows EventLog and sends alerts as SNMP messages.
SRPConnectionStatus	Monitors the percentage of uptime during a specified interval for the Server Routing Protocol (SRP) connection between the BlackBerry Enterprise Server and the Research in Motion (RIM) infrastructure.
SRPTest	Performs a test of the SRP connection to make sure the wireless network can be reached.
UserCountByServer	Lists the number of users on a BlackBerry Server and includes each user's association with a messaging (Exchange) server.
UserList	Lists the users on a BlackBerry Server, plus the total number of users on the BlackBerry Enterprise Server.

16.1 BesAlertForward

Use this Knowledge Script to send alerts using SNMP, MAPI Mail, Notes Mail, Pager, MessageBox, or another customized method whenever an event of a specified type occurs. Using this script, you can track Windows Event Log entries that match a filtering criterion.

16.1.1 Resource Object

BlackBerry Enterprise Server

16.1.2 Default Schedule

The default schedule is **Every 10 minutes**.

16.1.3 Setting Parameter Values

Set the following parameters as needed

Description	How to Set It
Raise event if matching event log entries found?	Set to **y** to raise events and send an alert. Default is y.
Collect data for event log entries?	Set to **y** to collect data for charts and reports. If set to y, returns the Event Log entries that matched your search criteria. Default is n.
Separate event data from different sources into multiple events?	Set to **y** to separate event entries from the different log files into different data streams. If you accept the default, n, all the event entries matching your filtering criteria are placed in the same data stream and the data detail message may include event entries from multiple log sources. For example, if you are monitoring both the System and Application logs, you may want to set this parameter to **y** so that events in the System log are tracked separately from events in the Application log. Default is n.
Filter by log source: ...System ...Security ...Application	Specify the event log you want to monitor. You can specify multiple event logs separated by commas. For example, `System,Security,Application`. Default is `Application`.
Filter by event type: ...Error ...Warning ...Information ...Success Audit ...Failure Audit	Set to **y** to monitor each type of event log entry. The default is y.
Filter by event source	Enter a string to direct the Knowledge Script to monitor events generated by a particular source, such as SQLExecutive, SNMP, or the Service Control Manager. The script looks for matching entries in the Event Log's **Source** field. You can enter multiple strings separated by commas and include or exclude criteria using a colon (:). If you are only specifying include criteria, the colon is not necessary. The default value is `BlackBerry`.

Description	How to Set It
Filter by event category	If you are interested in events in a particular category (for example, Server or Logon), enter an appropriate search string. The Knowledge Script looks for matching entries in the Event Log category field. You can enter multiple strings separated by commas and include or exclude criteria using a colon (:). If you are only specifying include criteria, the colon is not necessary.
Filter by event ID	If you are interested in particular event IDs, enter an appropriate search string or event ID range (for example, 100-2000). The Knowledge Script looks for matching entries in the Event Log's **Event** field. You can enter multiple IDs and ranges separated by commas. For example: `1,2, 10-15, 202` You can also include or exclude criteria using a colon (:). If you are only specifying include criteria, the colon is not necessary.
Filter by user	If you are interested in events associated with a particular user, enter an appropriate search string (for example, *DomainName**UserName*). The Knowledge Script looks for matching entries in the Event Log's **User** field. You can enter multiple strings separated by commas and include or exclude criteria using a colon (:). If you are only specifying include criteria, the colon is not necessary.
Filter by computer	If you are interested in events associated with a particular computer, enter an appropriate search string. The Knowledge Script looks for matching entries in the Event Log's **Computer** field. You can enter multiple strings separated by commas and include or exclude criteria using a colon (:). If you are only specifying include criteria, the colon is not necessary.
Filter by event description	If you are interested in events with a particular detail description, enter an appropriate search string. The Knowledge Script looks for matching entries in the Event Log's **Description** field. You can enter multiple strings separated by commas and include or exclude criteria using a colon (:). If you are only specifying include criteria, the colon is not necessary.
Maximum number of log entries per event	Specify the maximum number of entries to be recorded into each event detail message. If the Knowledge Script finds more entries from the log than can be placed in one event message, it returns multiple events to report all the outstanding entries in the log. The default is 30 entries.
Event severity when matching event log entries found	Set the event notification level to show the visibility for the event. The default severity level is 8. You may want to adjust the severity depending on which log or type of event you are checking for.

16.1.4 Example of How This Script is Used

The following is an example of how you can customize this script for your environment. For example, to detect security failures among the general system events, set the following options:

Properties and Parameters	Values for Detecting Security Failures
Schedule interval	Every 10 minutes
Event	y
Log	Security
Type	FailureAudit
Severity	2
Action	MapiMail

On the **Values** tab, set the "Event" parameter to **y** (indicating that an event is generated anytime the conditions are met), set "Log" and "Type" to "Security" and "FailureAudit" (indicating this to be a very serious and highly visible event). Leave the other filtering options blank.

On the **Actions** tab, indicate that an email message should be sent if an event is raised. AppManager checks for security failures and notifies a designated recipient with an email message if a security failure occurs.

Here's another example. To detect problems with a SQL Server, you can set the following options:

Properties and Parameters	Values for Detecting Security Failures
Schedule interval	30 minutes
Event?	y
Log	Application
Type	Error
Source	MSSQLServer
Severity	8
Action	MapiMail

You may want to collect data and graph a trend chart from your System Event Log. Here's how to set the other parameters:

Properties and Parameters	Values for Detecting Security Failures
Schedule interval	1 hour
Event?	y
Log	System
All other filters	not set
Action	null

View the first batch of filtered results in the detailed data message when you double-click a datapoint. Additional matching entries may be included in the graph.

16.2 DebugLogTotalSize

Use this Knowledge Script to calculate the total size of the local debug logs. If you choose to collect data, this Knowledge Script returns the number of MB of hard disk space used by the daily `debuglogYYYYMMDD.txt` files. An event is raised if the threshold you set for debug log size is exceeded.

NOTE: You may want to periodically use the PurgeDebugLog Knowledge Script to purge the debug log file.

16.2.1 Resource Object

BlackBerry Server

16.2.2 Default Schedule

The default interval is **Every 24 hours**.

16.2.3 Setting Parameter Values

Set the following parameters as needed.

Description	How to Set It
Raise event if threshold exceeded?	Set to **y** to raise an event when the size of the local debug log exceeds the threshold. Default is y.
Collect data for debug log file size (MB)?	Set to **y** to collect data for charts and reports. If set to **y**, returns the size of the local debug log in MB. Default is n.
Maximum event threshold for debug log file size	Enter the maximum event threshold for debug log file size. Enter a value from 0 to 32000 MB. Default is 1000 MB.
Event severity level when threshold exceeded	Set the event severity level, from 1 to 40, to indicate the importance of the event when monitoring fails. Enter a value from 1 to 40. Default is 5.

16.3 EventLog

Use this Knowledge Script to monitor information specific to the BlackBerry Enterprise Server that appears in the Windows Event Log. This script periodically scans the Windows Event Log for BlackBerry Enterprise Server service entries and raises an event if any are found. The event details specify the type of event that occurred.

If data is collected, this script returns the number of BlackBerry-related events in the Windows Event Log.

16.3.1 Resource Object

BlackBerry Enterprise Server

16.3.2 Default Schedule

The default interval for this script is **Every 5 minutes**.

16.3.3 Setting Parameter Values

Set the following parameters as needed.

Description	How to Set It
Raise event if log entries found?	Set to **y** to raise events when this Knowledge Script discovers BlackBerry Enterprise Server service entries in the Windows Event Log. Default is y.
Collect data for number and type of events found?	Set to **y** to collect data for charts and reports. If set to **y**, returns the number of new Event Log entries. Default is n.
Maximum number of log entries per event	Enter the maximum number of entries per event report. Enter a value from 1 to 100 entries. Default is 30 entries.
Event severity level when log entries found	Set the event severity level, from 1 to 40, to indicate the importance of the event. Adjust the severity depending on the types of events you are checking for. Default severity level is 8.

16.3.4 Example of How This Script is Used

Let's assume you ran this Knowledge Script once. The event details indicate that a `MAPI_E_LOGON` event occurred during the monitoring interval. This event indicates that the BlackBerry Enterprise Server cannot log on to the Exchange Server MAPI. You can then proceed to resolve the problem by re-establishing the MAPI connection so that the BlackBerry Enterprise Server service can send mail to the user.

16.4 ExchangeAvail

Use this Knowledge Script to measure the time taken to log on to the Exchange Server, and to check whether the Exchange Server is available.

This script also checks Exchange Server response time by measuring its response to a client request to open a mailbox. The script opens a selected mailbox on the Exchange Server to determine the availability of the BlackBerry Enterprise Server to the Exchange Link. This script then opens up a MAPI session to test whether the Exchange Server responds. The time taken to log on to the Exchange Server is recorded as the data stream used for the Report_ExchangeConnectivity report.

Specify a corresponding mailbox for each Exchange Server monitored. If an Exchange service is not accessible, an event is raised.

16.4.1 Resource Object

BlackBerry Enterprise Server

16.4.2 Default Schedule

The default interval is **Every 30 minutes**.

16.4.3 Setting Parameter Values

Set the following parameters as needed.

Description	How to Set It
Raise event if server unavailable or if threshold exceeded?	Set to **y** to raise an event if the Exchange Server is unavailable or if threshold is exceeded. The default is y.
Collect data for availability, response time, and connection time?	Set to **y** to collect data for charts and reports. If set to **y**, returns data about the availability, response and connection time of the selected Exchange Server(s).The default is y.
List of Exchange Servers	Create a list of Exchange Servers to monitor. Separate server names with ",". Default is "`Exchange_Server1`".
List of Exchange mailboxes	Create a list of the Exchange mailboxes to monitor. Separate mailbox names with ",". Default is "`Mailbox1`".
Full path to file with list of Exchange Servers and mailboxes	Enter a fully qualified path to a file containing a list of Exchange Server–Exchange mailbox pairs to monitor. Use the following format for the list: `Server name,Mailbox name`. Use commas to separate server and mailbox names. Each line in the file must contain a different server-mailbox pair.
Threshold – Maximum response time	Enter the maximum threshold (in seconds) for a response from: • Exchange Server • Exchange mailbox Enter a value from 0 to 100 seconds. Default is 60 seconds.

Description	How to Set It
Number of messages to retrieve to test response time.	Enter the number of messages to retrieve to determine the response time. Enter a value from 1 to 32,000 messages. Default is 10 messages.
Event severity when server unavailable or when threshold exceeded	Set the event severity level, from 1 to 40, to indicate the importance of the event for monitoring failure. Default is 8.

16.5 HungThreads

Use this Knowledge Script to monitor a BlackBerry Server service for "hung" threads. Hung threads decrease the number of requests that can be concurrently processed by the service. Any thread that starts and then does not finish is considered "hung."

NOTE: If you are using BlackBerry Enterprise Server version 2.1, you may be familiar with the term "blocked" threads, rather than "hung" threads. Both terms mean the same thing. In this guide, we use the term hung threads.

This Knowledge Script waits for a specified number of cycles before raising an event to see if the hung threads become unblocked. This waiting period is referred to as the "wait count."

An event is raised only when both the number of hung threads and the wait count (in cycles) exceed the specified thresholds. You also have the option to restart the hung service automatically. If you choose to collect data, this script returns data about the number of hung threads, the thread ID, and the wait count.

16.5.1 Resource Object

BlackBerry Server

16.5.2 Default Schedule

The default interval is **Every 10 minutes**.

16.5.3 Setting Parameter Values

Set the following parameters as needed.

Description	How to Set It
Raise event if threshold and wait count exceeded?	Set to **y** to raise events when the number of hung threads exceeds the threshold and wait count is exceeded. Default is y.
Collect data for hung threads, thread ID, and wait count?	Set to **y** to collect data for charts and reports. Default is n. If set to **y**, returns data about hung threads, including the thread ID and wait count.
Wait count	Set a wait count for each hung thread. The Knowledge Script waits the specified number of cycles to detect whether hung threads become unblocked. Default is 2 cycles.
Threshold – Maximum number of hung threads	Enter the maximum number of hung threads allowed. Enter a value from 1 to 100. Default is 1 thread.
Restart service if down?	Set to **y** to automatically restart a BlackBerry server service that's hung. Default is y.
Event severity for restart failure	Set the severity level, from 1 to 40, to indicate the importance if an attempt to restart a hung service failed. Default is 5.
Event severity for restart success	Set the severity level, from 1 to 40, to indicate the importance if an attempt to restart a hung service succeeded. Default is 25.
Event severity if restart disabled	Set the severity level, from 1 to 40, to indicate the importance if the "Restart service if down?" parameter is set to n. Default is 18.

16.6 MessagingServerList

Use this Knowledge Script to report the number of different Exchange Servers interacting with a BlackBerry Server service. Each Exchange Server must have at least one user on the BlackBerry Server.

An event is raised if the total number of messaging servers exceeds the threshold.

To ensure that this Knowledge Script works properly, check to make sure that the `BBUserAdminService` is running.

NOTE: This Knowledge Script requires the BBUserAdminClient executable to run. To ensure that this Knowledge Script works properly, first check to make sure that the BBUserAdminService is running.

16.6.1 Resource Object

BlackBerry Server

16.6.2 Default Schedule

The default schedule is **Every week**.

16.6.3 Setting Parameter Values

Set the following parameters as needed.

Description	How to Set It
Raise event on script success?	Set to **y** to raise an event if the job succeeds. Default is n.
Raise event if threshold exceeded?	Set to **y** to raise an event if the total number of messaging servers exceeds the threshold. Default is y.
Collect data for number of messaging servers?	Set to **y** to collect data for charts and reports. If set to **y**, returns the number of messaging servers for the selected BlackBerry Server service. Default is y.
Threshold – Maximum number of messaging servers	Enter the maximum number of different messaging servers that can be found for a single BlackBerry Server service before an event is raised. Default is 12 servers.
Path and filename for BBuserAdminClient executable	Enter the path and filename where the file `BBUserAdminClient.exe` is installed. Leave blank to accept the default path.
`BBUserAdminClient` executable timeout	Set a timeout value to determine how long the script attempts to reach the `BBUserAdminClient` executable. Enter a value from 1 to 120 seconds. Default is 10 seconds.
Event severity when threshold exceeded	Set the event severity level, from 1 to 40, to indicate the importance of the threshold-crossing event. Default is 25.

16.7 MsgAvgSize

Use this Knowledge Script to find the average message size (in KB) of the messages transferred to handhelds by a BlackBerry Server during the monitoring interval. This script considers email messages and calendar entries in its calculations. An event is raised if the average message size exceeds the threshold you set.

16.7.1 Resource Object

BlackBerry Server

16.7.2 Default Schedule

The default schedule is **Every 24 hours**.

16.7.3 Setting Parameter Values

Set the following parameters as needed.

Description	How to Set It
Raise event if threshold exceeded?	Set to **y** to raise an event if the average message size exceeds the threshold. Default is y.
Collect data for average message size?	Set to **y** to collect data for charts and reports. If set to **y**, returns the average message size of the messages transferred to handhelds during the monitoring interval. Default is n.
Threshold – Maximum average message size	Enter the maximum threshold for the average message size. Default is 2 KB.
Event severity when threshold exceeded	Set the event severity level, from 1 to 40, to indicate the importance of the threshold-crossing event. Default is 25.

16.8 MsgBytesReceived

Use this Knowledge Script to gather the total bytes received by handhelds per interval. This script does not consider bytes sent, but does consider calendar entries.

An event is raised when the threshold for total bytes received by handhelds is exceeded. If data is collected, the average number of bytes received by handhelds during the monitoring interval is returned.

16.8.1 Resource Object

BlackBerry Server

16.8.2 Default Schedule

The default schedule is **Every 24 hours**.

16.8.3 Setting Parameter Values

Set the following parameters as needed.

Description	How to Set It
Raise event if threshold exceeded?	Set to **y** to raise an event if the total bytes received by handhelds during the monitoring interval exceeds the threshold. Default is y.
Collect data for number of bytes transferred?	Set to **y** to collect data for charts and reports. If set to **y**, returns the average number of bytes received by handhelds during the monitoring interval. Default is n.
Threshold – Maximum bytes transferred	Enter the maximum number of bytes that can be received by handhelds before an event is raised. Default is 500 KB.
Event severity when threshold exceeded	Set the event severity level, from 1 to 40, to indicate the importance of the threshold-crossing event. Default is 25.

16.9 MsgsExpired

Use this Knowledge Script to monitor the number of messages that expired during the monitoring interval. A message intended for a BlackBerry handheld expires if seven days passes before it can be sent (if, for example, the handheld is turned off).

16.9.1 Resource Object

BlackBerry Enterprise Server

16.9.2 Default Schedule

The default schedule is **Every 5 minutes**.

16.9.3 Setting Parameter Values

Set the following parameters as needed.

Description	How to Set It
Raise event if threshold exceeded?	Set to **y** to raise an event if the number of expired messages exceeds the threshold. Default is y.
Collect data for number of expired messages?	Set to **y** to collect the number of expired messages per interval. Default is n.
Threshold – Maximum number of expired messages	Enter the maximum total number of expired messages that can occur before an event is raised. Default is 50.
Event severity when threshold exceeded	Set the event severity level, from 1 to 40, to indicate the importance of the event. Default is 8.

16.10 PurgeDebugLog

Use this Knowledge Script to monitor the total size of BlackBerry Enterprise Server debug log files. This script can be set to automatically purge a debug log, but only when a log exceeds both thresholds, for log file size and log age. An event is raised if either threshold is crossed.

NOTE: For a BlackBerry Enterprise Server with average load and an average number of users, the average debug log file size per day is estimated at 100 MB. The default threshold for log age (180 days) is based on having six months' worth of debug log data before starting the auto-purge.

16.10.1 Resource Object

BlackBerry Server

16.10.2 Default Schedule

The default interval is **Every 24 hours**.

16.10.3 Setting Parameter Values

Set the following parameters as needed.

Description	How to Set It
Event for total debug log file size?	Set to **y** to raise events when the total debug log file size exceeds threshold. Default is y.
Collect data for total debug log file size?	Set to **y** to collect data for charts and reports. If set to **y**, returns the total size (GB) and age (days) of the debug log. Default is n.
Threshold – Maximum total debug log file size	Enter the maximum total debug log file size (MB) allowed before an event is raised. Enter a value from 0 to 32000 MB. Default is 1000 MB.
Automatically purge debug log files?	Set to **y** to automatically purge the debug log file when both purge thresholds are exceeded (see below). Default is y.
Purge threshold – Maximum total debug log file size	Enter the maximum total debug log file size allowed before log is purged. Enter a value from 0 to 1000 GB. Default is 18 GB.
Purge threshold – Maximum debug log file age	Enter the maximum debug log file age (in days) allowed before the log is purged. Enter a value from 0 to 1000 days. Default is 180 days.
Raise event when debug log successfully purged?	Set to **y** to raise events when the debug log file is successfully purged. Default is y.
Collect data for number of debug log files purged and filenames?	Set to **y** to collect data for charts and events about the number of purged debug log files and their filenames. Default is n.
Event severity when log file size threshold exceeded	Set the event severity level, from 1 to 40, to indicate the importance of the event when monitoring fails. Default is 8.
Event severity when debug log file purged	Set the event severity level, from 1 to 40, to indicate the importance of the event when a log is deleted. Default is 35.

16.11 Report_EndToEndConnectivity

Use this Knowledge Script to generate a report about the connectivity between the Exchange and BlackBerry Enterprise Servers and a BlackBerry handheld. This report allows you to make a statistical analysis of the data point values (for example, the average or maximum value over a time period).

This report uses data collected by the ResponseTime Knowledge Script.

16.11.1 Resource Object

Report Agent > AM Repositories > *AppManager repository*

16.11.2 Default Schedule

The default schedule is **Run once**.

16.11.3 Setting Parameter Values

Set the following parameters as needed.

Description	How to Set It
Data source	Use the following parameters to select the data for your report.
Select computer(s)	Click the **Browse [...]** button to start the data wizard. Use the data wizard to select the computers for your report.
Select time range	Click the **Browse [...]** button to open the time browser. Set a specific or sliding time range for data included in your report.
Select peak weekday(s)	Click the **Browse [...]** button to select the days of the week to include in your report.
Data settings	Use the following parameters to define the statistical calculation applied to data, and which of the data is displayed.
Hours or percentage on chart	Select whether to illustrate availability by hours or by percentage.
Select sorting/display option	Select whether data is sorted, or the method of display: • **No sort**: Data is not sorted • **Sort**: Data is sorted by value (lowest to highest from front to back; highest to lowest from left to right) • **Top %**: Chart only the top *N* % of selected data (sorted by default) • **Top** *N*: Chart only the top *N* of selected data (sorted by default) • **Bottom %**: Chart only the bottom *N* % of data (sorted by default) • **Bottom** *N*: Chart only the bottom *N* of selected data (sorted by default)
Percentage/count for top/bottom	Enter a number for either the percent or count defined in the previous parameter (for example, Top 10%, or Top 10). Default is 25.

Description	How to Set It
Truncate top/bottom?	If set to yes, then the data table shows only the top or bottom N or % (for example, only the top 10%). Otherwise, the table shows all data. Default is no.
Report settings	Use the following parameters to define the graphical presentation of data, the folder where the report is generated, and properties that identify the report.
Include parameter help card?	Set to yes to include a table in the report that lists parameter settings for the report script. Default is yes.
Include table?	Set to yes to include a table of data stream values in the report. Default is yes.
Include chart?	Set to yes to include a chart of data stream values in the report. Default is yes.
Select chart style	Click the **Browse [...]** button to open the Chart Settings dialog box. Define the graphic properties of the charts in your report.
Select output folder	Click the **Browse [...]** button to set parameters for the output folder.
Add job ID to output folder name?	Set to yes to append the job ID to the name of the output folder. This is helpful to make the correlation between a specific instance of a Report Script and the corresponding report. Default is no.
Select properties	Click the **Browse [...]** button to open the Report Properties dialog box. Set the properties parameters as desired.
Add time stamp to title?	Set to yes to append a timestamp to the title of the report, making each title unique. The timestamp is made up of the date and time the report was generated. Adding a timestamp is useful in order to run consecutive iterations of the same report without overwriting previous output. Default is no.
Event notification	Use the following parameters to raise events associated with generating the report, and to set severity levels for those events.
Event for report success?	Set to yes to raise an event when the report is successfully generated. Default is yes.
Severity level for report success	Set the severity level, from 1 to 40, to indicate the importance of the event. Default is 35.
Severity level for report with no data	Set the severity level, from 1 to 40, to indicate the importance of the event. Default is 25.
Severity level for report failure	Set the severity level, from 1 to 40, to indicate the importance of the event. Default is 5.

16.12 Report_EndToEndResponseTime

Use this Knowledge Script to generate a report about Exchange Server response time. This report includes a measurement of the round-trip response time for a message to travel from a client mailbox, via a selected Exchange Server, to a BlackBerry Enterprise Server handheld, and for the handheld to send a response.

This report uses data collected by the ResponseTime Knowledge Script.

16.12.1 Resource Object

Report Agent > AM Repositories > *AppManager repository*

16.12.2 Default Schedule

The default schedule is **Run once**.

16.12.3 Setting Parameter Values

Set the following parameters as needed.

Description	How to Set It
Data source	Use the following parameters to select the data for your report.
Select computer(s)	Click the **Browse [...]** button to start the data wizard. Use the data wizard to select the computers for your report.
Select the style	Select the style for the first page of the report: • **By computer** provides links to pages showing the data collected from individual computers (each page shows all the data streams collected from a single computer) • **By data stream** provides links to pages showing a side-by-side comparison of values for the same data stream collected from different computers (each page shows, for example, the value of the *NT_CpuResource-All Threads(#)* data stream from each computer) • **By computer and data stream** provides links to pages showing a single data stream collected from a computer • **All data streams on one page** generates a report with all data on a single page
Select time range	Click the **Browse [...]** button to open the time browser. Set a specific or sliding time range for data included in your report.
Select peak weekday(s)	Click the **Browse [...]** button to select the days of the week to include in your report.
Aggregation by	Select the aggregation method for the data in your report: • Minute • Hour • Day
Aggregation interval	Select the interval by which the data in your report is aggregated. Possible values range from 1 to 90.

Description	How to Set It
Statistics to show per period	Select a statistical method by which to display data in the report: • **Average**: The average value of data points for the aggregation interval (for example, the average value for 1 Hour) • **Minimum**: The minimum value of data points for the aggregation interval • **Maximum**: The maximum value of data points for the aggregation interval • **Count**: The number of data points for the aggregation interval • **Sum**: The total value of data points for the aggregation interval • **3Sigma**: The average + (3 * standard deviation) and average - (3 * standard deviation) • **Std**: The standard deviation • **Box**: Lower fence, 25% point, median, 75% point, and upper fence for the aggregation interval • **Open**: The first value for the aggregation interval • **Close**: the last value for the aggregation interval
Report settings	Use the following parameters to define the graphical presentation of data, the folder where the report is generated, and properties that identify the report.
Include parameter help card?	Set to yes to include a table in the report that lists parameter settings for the report script. Default is yes.
Include table?	Set to yes to include a table of data stream values in the report. Default is yes.
Include chart?	Set to yes to include a chart of data stream values in the report. Default is yes.
Select chart style	Click the **Browse [...]** button to open the Chart Settings dialog box. Define the graphic properties of the charts in your report.
Select output folder	Click the **Browse [...]** button to set parameters for the output folder.
Add job ID to output folder name?	Set to yes to append the job ID to the name of the output folder. This is helpful to make the correlation between a specific instance of a Report Script and the corresponding report. Default is no.
Select properties	Click the **Browse [...]** button to open the Report Properties dialog box. Set the properties parameters as desired.
Add time stamp to title?	Set to yes to append a timestamp to the title of the report, making each title unique. The timestamp is made up of the date and time the report was generated. Adding a timestamp is useful in order to run consecutive iterations of the same report without overwriting previous output. Default is no.
Event notification	Use the following parameters to raise events associated with generating the report, and to set severity levels for those events.
Event for report success?	Set to yes to raise an event when the report is successfully generated. Default is yes.
Severity level for report success	Set the severity level, from 1 to 40, to indicate the importance of the event. Default is 35.
Severity level for report with no data	Set the severity level, from 1 to 40, to indicate the importance of the event. Default is 25.

Description	How to Set It
Severity level for report failure	Set the severity level, from 1 to 40, to indicate the importance of the event. Default is 5.

16.13 Report_ExchangeConnectionTime

Use this Knowledge Script to generate a report about the response time of Exchange services. This report measures the time taken to log on to the Exchange Server and helps make a statistical analysis of the data point values. For example, you can get the average or maximum value over a time period.

The ExchangeAvail Knowledge Script opens up a MAPI session to the Exchange Server to check availability. The script records the time taken to log on to the Exchange Server and uses this data stream to generate the report.

16.13.1 Resource Object

Report Agent > AM Repositories > *AppManager repository*

16.13.2 Default Schedule

The default schedule is **Run once**.

16.13.3 Setting Parameter Values

Set the following parameters as needed.

Description	How to Set It
Data source	Use the following parameters to select the data for your report.
Select computer(s)	Click the **Browse [...]** button to start the data wizard. Use the data wizard to select the computers for your report.
Select the style	Select the style for the first page of the report: • **By computer** provides links to pages showing the data collected from individual computers (each page shows all the data streams collected from a single computer) • **By data stream** provides links to pages showing a side-by-side comparison of values for the same data stream collected from different computers (each page shows, for example, the value of the *NT_CpuResource-All Threads(#)* data stream from each computer) • **By computer and data stream** provides links to pages showing a single data stream collected from a computer • **All data streams on one page** generates a report with all data on a single page
Select time range	Click the **Browse [...]** button to open the time browser. Set a specific or sliding time range for data included in your report.
Select peak weekday(s)	Click the **Browse [...]** button to select the days of the week to include in your report.
Aggregation by	Select the aggregation method for the data in your report: • Minute • Hour • Day

Description	How to Set It
Aggregation interval	Select the interval by which the data in your report is aggregated. Possible values range from 1 to 90.
Statistics to show per period	Select a statistical method by which to display data in the report: • **Average**: The average value of data points for the aggregation interval (for example, the average value for 1 Hour) • **Minimum**: The minimum value of data points for the aggregation interval • **Maximum**: The maximum value of data points for the aggregation interval • **Count**: The number of data points for the aggregation interval • **Sum**: The total value of data points for the aggregation interval • **3Sigma**: The average + (3 * standard deviation) and average - (3 * standard deviation) • **Std**: The standard deviation • **Box**: Lower fence, 25% point, median, 75% point, and upper fence for the aggregation interval • **Open**: The first value for the aggregation interval • **Close**: the last value for the aggregation interval
Report settings	Use the following parameters to define the graphical presentation of data, the folder where the report is generated, and properties that identify the report.
Include parameter help card?	Set to yes to include a table in the report that lists parameter settings for the report script. Default is yes.
Include table?	Set to yes to include a table of data stream values in the report. Default is yes.
Include chart?	Set to yes to include a chart of data stream values in the report. The default is yes.
Select chart style	Click the **Browse [...]** button to open the Chart Settings dialog box. Define the graphic properties of the charts in your report.
Select output folder	Click the **Browse [...]** button to set parameters for the output folder.
Add job ID to output folder name?	Set to yes to append the job ID to the name of the output folder. This is helpful to make the correlation between a specific instance of a Report Script and the corresponding report. Default is no.
Select properties	Click the **Browse [...]** button to open the Report Properties dialog box. Set the properties parameters as desired.
Add time stamp to title?	Set to yes to append a timestamp to the title of the report, making each title unique. The timestamp is made up of the date and time the report was generated. Adding a timestamp is useful in order to run consecutive iterations of the same report without overwriting previous output. Default is no.
Event notification	Use the following parameters to raise events associated with generating the report, and to set severity levels for those events.
Event for report success?	Set to yes to raise an event when the report is successfully generated. Default is yes.
Severity level for report success	Set the severity level, from 1 to 40, to indicate the importance of the event. Default is 35.

Description	How to Set It
Severity level for report with no data	Set the severity level, from 1 to 40, to indicate the importance of the event. Default is 25.
Severity level for report failure	Set the severity level, from 1 to 40, to indicate the importance of the event. Default is 5.

16.14 Report_ExchangeConnectivity

This report allows you to make a statistical analysis of the availability of the Exchange Server.

This report uses connectivity data collected by the ExchangeAvail Knowledge Script.

16.14.1 Resource Object

Report Agent > AM Repositories > *AppManager repository*

16.14.2 Default Schedule

The default schedule is **Run once**.

16.14.3 Setting Parameter Values

Set the following parameters as needed.

Description	How to Set It
Data source	Use the following parameters to select the data for your report.
Select computer(s)	Click the **Browse [...]** button to start the data wizard. Use the data wizard to select the computers for your report.
Select time range	Click the **Browse [...]** button to open the time browser. Set a specific or sliding time range for data included in your report.
Select peak weekday(s)	Click the **Browse [...]** button to select the days of the week to include in your report.
Data settings	Use the following parameters to define the statistical calculation applied to data, and which of the data is displayed.
Hours or percentage on chart	Select whether to illustrate availability by hours or by percentage.
Select sorting/display option	Select whether data is sorted, or the method of display: • **No sort**: Data is not sorted • **Sort**: Data is sorted by value (lowest to highest from front to back; highest to lowest from left to right) • **Top %**: Chart only the top *N* % of selected data (sorted by default) • **Top** *N*: Chart only the top *N* of selected data (sorted by default) • **Bottom %**: Chart only the bottom *N* % of data (sorted by default) • **Bottom** *N*: Chart only the bottom *N* of selected data (sorted by default)
Percentage/count for top/bottom	Enter a number for either the percent or count defined in the previous parameter (for example, Top 10%, or Top 10). Default is 25.
Truncate top/bottom?	If set to yes, then the data table shows only the top or bottom *N* or % (for example, only the top 10%). Otherwise, the table shows all data. Default is no.

Description	How to Set It
Report settings	Use the following parameters to define the graphical presentation of data, the folder where the report is generated, and properties that identify the report.
Include parameter help card?	Set to yes to include a table in the report that lists parameter settings for the report script. Default is yes.
Include table?	Set to yes to include a table of data stream values in the report. Default is yes.
Include chart?	Set to yes to include a chart of data stream values in the report. Default is yes.
Select chart style	Click the **Browse [...]** button to open the Chart Settings dialog box. Define the graphic properties of the charts in your report.
Select output folder	Click the **Browse [...]** button to set parameters for the output folder.
Add job ID to output folder name?	Set to yes to append the job ID to the name of the output folder. This is helpful to make the correlation between a specific instance of a Report Script and the corresponding report. The default is no.
Select properties	Click the **Browse [...]** button to open the Report Properties dialog box. Set the properties parameters as desired.
Add time stamp to title?	Set to yes to append a timestamp to the title of the report, making each title unique. The time stamp is made up of the date and time the report was generated. Adding a time stamp is useful in order to run consecutive iterations of the same report without overwriting previous output. The default is no.
Event notification	Use the following parameters to raise events associated with generating the report, and to set severity levels for those events.
Event for report success?	Set to yes to raise an event when the report is successfully generated. Default is yes.
Severity level for report success	Set the severity level, from 1 to 40, to indicate the importance of the event. Default is 35.
Severity level for report with no data	Set the severity level, from 1 to 40, to indicate the importance of the event. Default is 25.
Severity level for report failure	Set the severity level, from 1 to 40, to indicate the importance of the event. Default is 5.

16.15 Report_MessagesByInterval

Use this Knowledge Script to generate a report about new message traffic, including the number of messages sent, queued, received, and filtered, and the total number of new messages during the monitoring interval.

This report uses data collected by the ServerLoad Knowledge Script.

16.15.1 Resource Object

Report Agent > AM Repositories > *AppManager repository*

16.15.2 Default Schedule

The default schedule is **Run once**.

16.15.3 Setting Parameter Values

Set the following parameters as needed.

Description	How to Set It
Data source	Use the following parameters to select the data for your report.
Select computer(s)	Click the **Browse [...]** button to start the data wizard. Use the data wizard to select the computers for your report.
Select the style	Select the style for the first page of the report: • **By computer** provides links to pages showing the data collected from individual computers (each page shows all the data streams collected from a single computer) • **By data stream** provides links to pages showing a side-by-side comparison of values for the same data stream collected from different computers (each page shows, for example, the value of the *NT_CpuResource-All Threads(#)* data stream from each computer) • **By computer and data stream** provides links to pages showing a single data stream collected from a computer • **All data streams on one page** generates a report with all data on a single page
Select time range	Click the **Browse [...]** button to open the time browser. Set a specific or sliding time range for data included in your report.
Select peak weekday(s)	Click the **Browse [...]** button to select the days of the week to include in your report.
Aggregation by	Select the aggregation method for the data in your report: • Minute • Hour • Day
Aggregation interval	Select the interval by which the data in your report is aggregated. Possible values range from 1 to 90.

Description	How to Set It
Statistics to show per period	Select a statistical method by which to display data in the report: • **Average**: The average value of data points for the aggregation interval (for example, the average value for 1 Hour) • **Minimum**: The minimum value of data points for the aggregation interval • **Maximum**: The maximum value of data points for the aggregation interval • **Count**: The number of data points for the aggregation interval • **Sum**: The total value of data points for the aggregation interval • **3Sigma**: The average + (3 * standard deviation) and average - (3 * standard deviation) • **Std**: The standard deviation • **Box**: Lower fence, 25% point, median, 75% point, and upper fence for the aggregation interval • **Open**: The first value for the aggregation interval • **Close**: the last value for the aggregation interval
Report settings	Use the following parameters to define the graphical presentation of data, the folder where the report is generated, and properties that identify the report.
Include parameter help card?	Set to yes to include a table in the report that lists parameter settings for the report script. Default is yes.
Include table?	Set to yes to include a table of data stream values in the report. Default is yes.
Include chart?	Set to yes to include a chart of data stream values in the report. The default is yes.
Select chart style	Click the **Browse [...]** button to open the Chart Settings dialog box. Define the graphic properties of the charts in your report.
Select output folder	Click the **Browse [...]** button to set parameters for the output folder.
Add job ID to output folder name?	Set to yes to append the job ID to the name of the output folder. This is helpful to make the correlation between a specific instance of a Report Script and the corresponding report. Default is no.
Select properties	Click the **Browse [...]** button to open the Report Properties dialog box. Set the properties parameters as desired.
Add time stamp to title?	Set to yes to append a timestamp to the title of the report, making each title unique. The timestamp is made up of the date and time the report was generated. Adding a timestamp is useful in order to run consecutive iterations of the same report without overwriting previous output. Default is no.
Event notification	Use the following parameters to raise events associated with generating the report, and to set severity levels for those events.
Event for report success?	Set to yes to raise an event when the report is successfully generated. Default is yes.
Severity level for report success	Set the severity level, from 1 to 40, to indicate the importance of the event. Default is 35.
Severity level for report with no data	Set the severity level, from 1 to 40, to indicate the importance of the event. Default is 25.

Description	How to Set It
Severity level for report failure	Set the severity level, from 1 to 40, to indicate the importance of the event. Default is 5.

16.16 Report_MessageSummary

Use this Knowledge Script to generate a summary of total new message traffic during a monitoring interval, including the number of sent, received, and filtered messages.

This report uses data collected by the ServerLoad Knowledge Script.

16.16.1 Resource Object

Report Agent > AM Repositories > *AppManager repository*

16.16.2 Default Schedule

The default schedule is **Run once**.

16.16.3 Setting Parameter Values

Set the following parameters as needed.

Description	How to Set It
Data source	Use the following parameters to select the data for your report.
Select computer(s)	Click the **Browse [...]** button to start the data wizard. Use the data wizard to select the computers for your report.
Select time range	Click the **Browse [...]** button to open the time browser. Set a specific or sliding time range for data included in your report.
Select peak weekday(s)	Click the **Browse [...]** button to select the days of the week to include in your report.
Select the style	Select the style for the report: • **By computer** shows one value for each computer you selected. • **By legend** shows one value for each different legend (the legend is a truncated form of the data stream legend visible in the Operator Console). • **By computer and legend** shows one value for each unique legend from each computer.
Data settings	Use the following parameters to define the statistical calculation applied to data, and which of the data is displayed.

Description	How to Set It
Statistics to show	Select a statistical method by which to display data in the report: • **Average**: The average value of data points for the time range of the report • **Minimum**: The minimum value of data points for the time range of the report • **Maximum**: The maximum value of data points for the time range of the report • **Min**/**Avg**/**Max**: The minimum, average, and maximum values of data points for the time range of the report • **Range**: The range of values in the data stream (maximum - minimum = range) • **StandardDeviation**: The measure of how widely values are dispersed from the mean • **Sum**: The total value of data points for the time range of the report • **Close**: The last value for the time range of the report • **Change**: The difference between the first and last values for the time range of the report (close - open = change) • **Count**: The number of data points for the time range of the report
Select sorting/display option	Select whether data is sorted, or the method of display: • **No sort**: Data is not sorted • **Sort**: Data is sorted by value (lowest to highest from front to back; highest to lowest from left to right) • **Top %**: Chart only the top *N* % of selected data (sorted by default) • **Top** *N*: Chart only the top *N* of selected data (sorted by default) • **Bottom %**: Chart only the bottom *N* % of data (sorted by default) • **Bottom** *N*: Chart only the bottom *N* of selected data (sorted by default)
Percentage/count for top/bottom	Enter a number for either the percent or count defined in the previous parameter (for example, Top 10%, or Top 10). The default is 25.
Truncate top/bottom?	If set to yes, then the data table shows only the top or bottom N or % (for example, only the top 10%). Otherwise, the table shows all data. Default is no.
Show totals on the table?	If set to yes, then additional calculations are made for each column of numbers in a table, and the following values are listed at the end of the table: • **Report Average**: An average of all values in a column • **Report Minimum**: The minimum value in a column • **Report Maximum**: The maximum value in a column • **Report Total**: The total of all values in a column Default is no.
Report settings	Use the following parameters to define the graphical presentation of data, the folder where the report is generated, and properties that identify the report.
Include parameter help card?	Set to yes to include a table in the report that lists parameter settings for the report script. Default is yes.
Include table?	Set to yes to include a table of data stream values in the report. Default is yes.
Include chart?	Set to yes to include a chart of data stream values in the report. Default is yes.

Description	How to Set It
Select chart style	Click the **Browse [...]** button to open the Chart Settings dialog box. Define the graphic properties of the charts in your report.
Select output folder	Click in the Value column, and click the **Browse [...]** button to set parameters for the output folder.
Add job ID to output folder name?	Set to yes to append the job ID to the name of the output folder. This is helpful to make the correlation between a specific instance of a Report Script and the corresponding report. Default is no.
Select properties	Click the **Browse [...]** button to open the Report Properties dialog box. Set the properties parameters as desired.
Add time stamp to title?	Set to yes to append a timestamp to the title of the report, making each title unique. The timestamp is made up of the date and time the report was generated. Adding a timestamp is useful in order to run consecutive iterations of the same report without overwriting previous output. Default is no.
Event notification	Use the following parameters to raise events associated with generating the report, and to set severity levels for those events.
Event for report success?	Set to yes to raise an event when the report is successfully generated. Default is yes.
Severity level for report success	Set the severity level, from 1 to 40, to indicate the importance of the event. Default is 35.
Severity level for report with no data	Set the severity level, from 1 to 40, to indicate the importance of the event. Default is 25.
Severity level for report failure	Set the severity level, from 1 to 40, to indicate the importance of the event. Default is 5.

16.17 Report_ServerList

Use this script to generate a report listing all the Exchange Servers that are interacting with a BlackBerry Server service. To be included, each Exchange Server must have at least one user on the BlackBerry Enterprise Server. This report shows the Mail Server name, the organizational unit, and the server type. This script uses data collected by the MessagingServerList Knowledge Script.

16.17.1 Resource Object

Report Agent > AM Repositories > *AppManager repository*

16.17.2 Default Schedule

The default schedule is **Run once**.

16.17.3 Setting Parameter Values

Set the following parameters as needed.

Description	How to Set It
Data source	Use the following parameters to select the data for your report.
Select computers	Click the **Browse [...]** button to start the data wizard. Use the data wizard to select the computers for your report.
Select time range	Click the **Browse [...]** button to open the time browser. Set a specific or sliding time range for data included in your report.
Report settings	Use the following parameters to define the graphical presentation of data, the folder where the report is generated, and properties that identify the report.
Include parameter help card?	Set to yes to include a table in the report that lists parameter settings for the report script. Default is yes.
Select output folder	Click the **Browse [...]** button to set parameters for the output folder.
Add job ID to output folder name?	Set to yes to append the job ID to the name of the output folder. This is helpful to make the correlation between a specific instance of a Report Script and the corresponding report. Default is no.
Select properties	Click the **Browse [...]** button to open the Report Properties dialog box. Set the properties parameters as desired.
Add time stamp to title?	Set to yes to append a timestamp to the title of the report, making each title unique. The timestamp is made up of the date and time the report was generated. Adding a timestamp is useful in order to run consecutive iterations of the same report without overwriting previous output. Default is no.
Event notification	Use the following parameters to raise events associated with generating the report, and to set severity levels for those events.

Description	How to Set It
Event for report success?	Set to yes to raise an event when the report is successfully generated. Default is yes.
Severity level for report success	Set the severity level, from 1 to 40, to indicate the importance of the event. Default is 35.
Severity level for report with no data	Set the severity level, from 1 to 40, to indicate the importance of the event. Default is 25.
Severity level for report failure	Set the severity level, from 1 to 40, to indicate the importance of the event. Default is 5.

16.18 Report_SRPConnectionUptime

Use this Knowledge Script to generate a report about the percentage of uptime for the Server Routing Protocol (SRP) connection over a specified time period.

This report uses data collected by the SRPConnectionStatus Knowledge Script.

16.18.1 Resource Object

Report Agent > AM Repositories > *AppManager repository*

16.18.2 Default Schedule

The default schedule is **Run once**.

16.18.3 Setting Parameter Values

Set the following parameters as needed.

Description	How to Set It
Data source	Use the following parameters to select the data for your report.
Select computer(s)	Click the **Browse [...]** button to start the data wizard. Use the data wizard to select the computers for your report.
Select the style	Select the style for the first page of the report: • **By computer** provides links to pages showing the data collected from individual computers (each page shows all the data streams collected from a single computer) • **By data stream** provides links to pages showing a side-by-side comparison of values for the same data stream collected from different computers (each page shows, for example, the value of the *NT_CpuResource-All Threads(#)* data stream from each computer) • **By computer and data stream** provides links to pages showing a single data stream collected from a computer • **All data streams on one page** generates a report with all data on a single page
Select time range	Click the **Browse [...]** button to open the time browser. Set a specific or sliding time range for data included in your report.
Select peak weekday(s)	Click the **Browse [...]** button to select the days of the week to include in your report.
Aggregation by	Select the aggregation method for the data in your report: • Minute • Hour • Day
Aggregation interval	Select the interval by which the data in your report is aggregated. Possible values range from 1 to 90.

Description	How to Set It
Statistics to show per period	Select a statistical method by which to display data in the report: • **Average**: The average value of data points for the aggregation interval (for example, the average value for 1 Hour) • **Minimum**: The minimum value of data points for the aggregation interval • **Maximum**: The maximum value of data points for the aggregation interval • **Count**: The number of data points for the aggregation interval • **Sum**: The total value of data points for the aggregation interval • **3Sigma**: The average + (3 * standard deviation) and average - (3 * standard deviation) • **Std**: The standard deviation • **Box**: Lower fence, 25% point, median, 75% point, and upper fence for the aggregation interval • **Open**: The first value for the aggregation interval • **Close**: the last value for the aggregation interval
Report settings	Use the following parameters to define the graphical presentation of data, the folder where the report is generated, and properties that identify the report.
Include parameter help card?	Set to yes to include a table in the report that lists parameter settings for the report script. Default is yes.
Include table?	Set to yes to include a table of data stream values in the report. Default is yes.
Include chart?	Set to yes to include a chart of data stream values in the report. The default is yes.
Select chart style	Click the **Browse [...]** button to open the Chart Settings dialog box. Define the graphic properties of the charts in your report.
Select output folder	Click the **Browse [...]** button to set parameters for the output folder.
Add job ID to output folder name?	Set to yes to append the job ID to the name of the output folder. This is helpful to make the correlation between a specific instance of a Report Script and the corresponding report. Default is no.
Select properties	Click the **Browse [...]** button to open the Report Properties dialog box. Set the properties parameters as desired.
Add time stamp to title?	Set to yes to append a timestamp to the title of the report, making each title unique. The timestamp is made up of the date and time the report was generated. Adding a time stamp is useful in order to run consecutive iterations of the same report without overwriting previous output. Default is no.
Event notification	Use the following parameters to raise events associated with generating the report, and to set severity levels for those events.
Event for report success?	Set to yes to raise an event when the report is successfully generated. Default is yes.
Severity level for report success	Set the severity level, from 1 to 40, to indicate the importance of the event. Default is 35.
Severity level for report with no data	Set the severity level, from 1 to 40, to indicate the importance of the event. Default is 25.

Description	How to Set It
Severity level for report failure	Set the severity level, from 1 to 40, to indicate the importance of the event. Default is 5.

16.19 Report_SRPConnectivity

Use this Knowledge Script to generate a report about the connectivity (up or down) of the BlackBerry Server SRP connection over a specified period.

This report uses data collected by the SRPConnectionStatus Knowledge Script.

16.19.1 Resource Objects

Report Agent > AM Repositories > *AppManager repository*

16.19.2 Default Schedule

The default schedule is **Run once**.

16.19.3 Setting Parameter Values

Set the following parameters as needed.

Description	How to Set It
Data source	Use the following parameters to select the data for your report.
Select computer(s)	Click the **Browse [...]** button to start the data wizard. Use the data wizard to select the computers for your report.
Select time range	Click the **Browse [...]** button to open the time browser. Set a specific or sliding time range for data included in your report.
Select peak weekday(s)	Click the **Browse [...]** button to select the days of the week to include in your report.
Data settings	Use the following parameters to define the statistical calculation applied to data, and which of the data is displayed.
Hours or percentage on chart	Select whether to illustrate availability by hours or by percentage.
Select sorting/display option	Select whether data is sorted, or the method of display: • **No sort**: Data is not sorted • **Sort**: Data is sorted by value (lowest to highest from front to back; highest to lowest from left to right) • **Top %**: Chart only the top *N* % of selected data (sorted by default) • **Top** *N*: Chart only the top *N* of selected data (sorted by default) • **Bottom %**: Chart only the bottom *N* % of data (sorted by default) • **Bottom** *N*: Chart only the bottom *N* of selected data (sorted by default)
Percentage/count for top/bottom	Enter a number for either the percent or count defined in the previous parameter (for example, Top 10%, or Top 10). Default is 25.

Description	How to Set It
Truncate top/bottom?	If set to yes, the data table shows only the top or bottom N or % (for example, only the top 10%). Otherwise, the table shows all data. Default is no.
Report settings	Use the following parameters to define the graphical presentation of data, the folder where the report is generated, and properties that identify the report.
Include parameter help card?	Set to yes to include a table in the report that lists parameter settings for the report script. Default is yes.
Include table?	Set to yes to include a table of data stream values in the report. Default is yes.
Include chart?	Set to yes to include a chart of data stream values in the report. Default is yes.
Select chart style	Click the **Browse [...]** button to open the Chart Settings dialog box. Define the graphic properties of the charts in your report.
Select output folder	Click the **Browse [...]** button to set parameters for the output folder.
Add job ID to output folder name?	Set to yes to append the job ID to the name of the output folder. This is helpful to make the correlation between a specific instance of a Report Script and the corresponding report. Default is no.
Select properties	Click the **Browse [...]** button to open the Report Properties dialog box. Set the properties parameters as desired.
Add time stamp to title?	Set to yes to append a timestamp to the title of the report, making each title unique. The timestamp is made up of the date and time the report was generated. Adding a timestamp is useful in order to run consecutive iterations of the same report without overwriting previous output. Default is no.
Event notification	Use the following parameters to raise events associated with generating the report, and to set severity levels for those events.
Event for report success?	Set to yes to raise an event when the report is successfully generated. Default is yes.
Severity level for report success	Set the severity level, from 1 to 40, to indicate the importance of the event. Default is 35.
Severity level for report with no data	Set the severity level, from 1 to 40, to indicate the importance of the event. Default is 25.
Severity level for report failure	Set the severity level, from 1 to 40, to indicate the importance of the event. Default is 5.

16.20 Report_UserByServer

Use this Knowledge Script to generate a report about the number of users on a BlackBerry Server service. Users are listed and sorted by their association with a messaging server.

This report uses data collected by the UserCountByServer Knowledge Script.

16.20.1 Resource Object

Report Agent > AM Repositories > *AppManager repository*

16.20.2 Default Schedule

The default schedule is **Run once**.

16.20.3 Setting Parameter Values

Set the following parameters as needed.

Description	How to Set It
Data source	Use the following parameters to select the data for your report.
Select computer(s)	Click the **Browse [...]** button to start the data wizard. Use the data wizard to select the computers for your report.
Select time range	Click the **Browse [...]** button to open the time browser. Set a specific or sliding time range for data included in your report.
Report settings	Use the following parameters to define the graphical presentation of data, the folder where the report is generated, and properties that identify the report.
Include parameter help card?	Set to yes to include a table in the report that lists parameter settings for the report script. Default is yes.
Select output folder	Click the **Browse [...]** button to set parameters for the output folder.
Add job ID to output folder name?	Set to yes to append the job ID to the name of the output folder. This is helpful to make the correlation between a specific instance of a Report Script and the corresponding report. Default is no.
Select properties	Click the **Browse [...]** button to open the Report Properties dialog box. Set the properties parameters as desired.
Add time stamp to title?	Set to yes to append a timestamp to the title of the report, making each title unique. The timestamp is made up of the date and time the report was generated. Adding a timestamp is useful in order to run consecutive iterations of the same report without overwriting previous output. Default is no.
Event notification	Use the following parameters to raise events associated with generating the report, and to set severity levels for those events.

Description	How to Set It
Event for report success?	Set to yes to raise an event when the report is successfully generated. Default is yes.
Severity level for report success	Set the severity level, from 1 to 40, to indicate the importance of the event. Default is 35.
Severity level for report with no data	Set the severity level, from 1 to 40, to indicate the importance of the event. Default is 25.
Severity level for report failure	Set the severity level, from 1 to 40, to indicate the importance of the event. Default is 5.

16.21 Report_UserListing

Use this Knowledge Script to generate a report about the number of users on a BlackBerry Server service. Users are listed and sorted by their association with a messaging server.

This report uses data collected by the UserList Knowledge Script.

16.21.1 Resource Object

Report Agent > AM Repositories > *AppManager repository*

16.21.2 Default Schedule

The default schedule is **Run once**.

16.21.3 Setting Parameter Values

Set the following parameters as needed.

Description	How to Set It
Data source	Use the following parameters to select the data for your report.
Select computer(s)	Click the **Browse [...]** button to start the data wizard. Use the data wizard to select the computers for your report.
Select time range	Click the **Browse [...]** button to open the time browser. Set a specific or sliding time range for data included in your report.
Report settings	Use the following parameters to define the graphical presentation of data, the folder where the report is generated, and properties that identify the report.
Include parameter help card?	Set to yes to include a table in the report that lists parameter settings for the report script. Default is yes.
Select output folder	Click the **Browse [...]** button to set parameters for the output folder.
Add job ID to output folder name?	Set to yes to append the job ID to the name of the output folder. This is helpful to make the correlation between a specific instance of a Report Script and the corresponding report. Default is no.
Select properties	Click the **Browse [...]** button to open the Report Properties dialog box. Set the properties parameters as desired.
Add time stamp to title?	Set to yes to append a timestamp to the title of the report, making each title unique. The timestamp is made up of the date and time the report was generated. Adding a timestamp is useful in order to run consecutive iterations of the same report without overwriting previous output. Default is no.
Event notification	Use the following parameters to raise events associated with generating the report, and to set severity levels for those events.

Description	How to Set It
Event for report success?	Set to yes to raise an event when the report is successfully generated. Default is yes.
Severity level for report success	Set the severity level, from 1 to 40, to indicate the importance of the event. Default is 35.
Severity level for report with no data	Set the severity level, from 1 to 40, to indicate the importance of the event. Default is 25.
Severity level for report failure	Set the severity level, from 1 to 40, to indicate the importance of the event. Default is 5.

16.22 ResponseTime

Use this Knowledge Script to measure the round-trip response time of an email message sent to a BlackBerry handheld and a response received from the handheld. Response time is measured using a pair of script iterations. The first time this Knowledge Script runs, the AppManager agent on the selected computer sends a test email message from the mailbox specified in the "Sender Mailbox" parameter to the handheld by way of a specified Exchange Server (the "Sender Mail Server" parameter).

The test message includes an instruction to the handheld to send an automated reply. On the second script iteration, the agent checks for the reply and calculates the response time. The BlackBerry Enterprise Server places a timestamp on the message on its way to the handheld and a timestamp on the reply sent from the handheld. The agent uses these timestamps to calculate the response time.

An event is raised if the response-time threshold is crossed. An event may also indicate that messages failed to be sent or delivered.

16.22.1 Resource Object

BlackBerry Enterprise Server

16.22.2 Default Schedule

The default interval is **Every 30 minutes**.

16.22.3 Setting Parameter Values

Set the following parameters as needed.

Description	How to Set It
Raise event if threshold exceeded?	Set to **y** to raise an event if the response time exceeds the threshold. Default is y.
Collect data for round-trip response time?	Set to **y** to collect data for charts and reports. If set to **y**, returns the round-trip response time for the email message. Default is y.
Threshold – Maximum response time	Enter the maximum response time (in seconds) allowed for the email message to be sent and for a response to be received before an event is raised. Enter a value from 0 to 32000 seconds. Default is 180 seconds.
Sender Mailbox (originates test message)	Enter the name of the mailbox from which the test email message should be sent to the handheld. Default is `netiq-blackberry`.
Sender Mail Server (sends test message to handheld)	Enter the name of the mail server through which the email message should be sent. Default is `mail-server`.
Email address of handheld (receives test message)	Enter the email address of the handheld device that will receive the test message via SMTP and reply to it. Default is `netiq-test-reply@netiq.com`.
Event severity when threshold exceeded	Set the event severity level, from 1 to 40, to indicate the importance of the event. Default is 8.

16.23 ServerHealth

Use this Knowledge Script to monitor BlackBerry Enterprise Server health. This script monitors the percentage of memory and of CPU time used by instances of the BlackBerry Server service (`BlackBerryServer.exe`). For versions 3.5 and 3.6 of the BlackBerry Enterprise Server, up to 4 instances of this process may be running; their utilization percentages are then totaled. Earlier versions of BlackBerry Enterprise Server do not support multiple instances of `BlackBerryServer.exe`.

If the memory or CPU utilization exceeds either of the thresholds you set, an event is raised.

16.23.1 Resource Object

BlackBerry Enterprise Server

16.23.2 Default Schedule

The default interval is **Every 5 minutes**.

16.23.3 Setting Parameter Values

Set the following parameters as needed.

Description	How to Set It
Raise event if either threshold exceeded?	Set to **y** to raise an event when a threshold is exceeded. Default is y.
Collect data for memory and CPU utilization?	Set to **y** to collect data for charts and reports. If set to **y**, reports the percentage of memory and of CPU time used by the BlackBerry Enterprise Server processes and compares the data collected in the current monitoring interval to that of the previous monitoring interval. Any graphs you create plot the delta rather than the total value. Default is n.
Threshold – Maximum memory utilization	Enter the maximum percentage of memory that can be used before an event is raised. Enter a value from 0% to 100%. Default is 50%.
Threshold – Maximum CPU utilization	Enter the maximum CPU utilization (%) allowed by the BlackBerry Enterprise Server processes before an event is raised. Enter values from 0% to 100%. Default is 50%.
Event severity when threshold exceeded	Set the event severity level, from 1 to 40, to indicate the importance of the threshold-crossing event. Default is 8.

16.24 ServerLoad

Use this Knowledge Script to monitor the number of new messages filtered, sent, received, or queued during an interval. This script also monitors the total number of new messages for the interval.

NOTE: It's a good idea to set a low threshold so the queue doesn't grow too large.

If any of the thresholds you set for the number of new, filtered, sent, received, or queued messages is exceeded, an event is raised.

The total of all new messages is measured by calculating at each script iteration the change (delta) between the previous count and the current count of the following:

- Positive change in messages filtered
- Positive change in messages sent
- Positive change in messages received
- Positive or negative change in number of messages in the current queue

NOTE: The total number of new messages is 0 if there are no new messages. However, the count could also be 0 if the BlackBerry Enterprise administrator resets the Global Redirection Filter statistics counter in the Microsoft Management Console (MMC) to 0.

16.24.1 Resource Object

BlackBerry Enterprise Server

16.24.2 Default Schedule

The default interval is **Every 5 minutes**.

16.24.3 Setting Parameter Values

Set the following parameters as needed.

Description	How to Set It
Raise event if any threshold exceeded?	Set to **y** to raise an event for the number of new messages filtered, sent, received, or queued during an interval. Default is y.
Collect data for new messages filtered, sent, received, or queued?	Set to **y** to collect data for charts and events. If set to **y**, collects number of messages filtered, sent, received, or queued, and total number of new messages during a monitoring interval. Default is n.
Threshold – Maximum number of messages filtered	Enter the maximum number of messages that can be filtered before an event is raised. Enter a value from 0 to 9999 messages. Default is 50 messages.
Threshold – Maximum number of messages sent	Enter the maximum number of messages that can be sent before an event is raised. Enter a value from 0 to 9999 messages. Default is 50 messages.

Description	How to Set It
Threshold – Maximum number of messages received	Enter the maximum number of messages that can be received before an event is raised. Enter a value from 0 to 9999 messages. Default is 50 messages.
Threshold – Maximum number of messages queued for delivery	Enter the maximum number of messages that can be queued for delivery before an event is raised. Enter a value from 0 to 9999 messages. Default is 50 messages.
Threshold – Maximum total new messages	Enter the maximum total number of new messages for the monitoring interval. Enter a value from 0 to 9,999 messages. Default is 50 messages.
Event severity when any threshold exceeded	Set the event severity level, from 1 to 40, to indicate the importance of the event. Default is 8.

16.25 ServicesDown

Use this Knowledge Script to monitor the up or down status of BlackBerry Enterprise Server services. You also have the option to restart a service that is down. If any BlackBerry Enterprise Server service is down, or if an attempt to restart fails or succeeds, an event is raised.

You can customize this script to perform the following tasks:

- Restart any service that is down.
- Raise an event if attempt to restart succeeds or fails, or if the "Restart service if down?" parameter is disabled.
- Perform specified actions, such as sending an email to an associated user, when specified events are raised.

You can monitor any or all of the following services:

- BlackBerry Enterprise Server Alert
- BlackBerry Enterprise Server User Admin service
- BlackBerry Server service

16.25.1 Resource Object

BlackBerry Enterprise Server

16.25.2 Default Schedule

The default interval is **Every 30 minutes**.

16.25.3 Setting Parameter Values

Set the following parameters as needed.

Description	How to Set It
Collect data for service status?	Set to **y** to collect data for charts and reports. If set to **y**, returns the following: • 100 – service is up. • 0 – service is down. • The percentage of time a service was up. Default is n.
Restart service if down?	Set to **y** to automatically restart any service that is detected down. Default is y.
Event severity for restart failure	Set the event severity level, from 1 to 40, to indicate the importance of the event if the service is down and AppManager cannot restart it. Default is 5.
Event severity for restart success	Set the event severity level, from 1 to 40, to indicate the importance of the event if the service was down and AppManager successfully restarted it. Default is 25.

Description	How to Set It
Event severity when Restart parameter disabled	Set the event severity level, from 1 to 40, to indicate the importance of the event if the service is down and AppManager has not been set to restart it. Default is 18.
Monitor BlackBerry Enterprise Server?	Set to **y** to monitor the BlackBerry Enterprise Server. Default is y.
Monitor BESAlert?	Set to **y** to monitor the `BlackBerryAlert` service. Default is y.
Monitor BBUserAdminService?	Set to **y** to monitor the `BBUserAdmin` service. Default is n.
Monitor BlackBerry Mobile Data Server service?	Set to **y** to monitor the BlackBerry Server Mobile Data Server service. This service is only available on BlackBerry Enterprise Server versions 3.5 and later. Default is n.
Check BlackBerry Database Consistency Service?	Set to **y** to monitor the BlackBerry Database Consistency Service. This service is only available on BlackBerry Enterprise Server versions 3.5 and higher. Default is n.
List of services to monitor (comma-separated)	List services to monitor, separated by commas (,). For example: `BBUserAdmin,BlackBerryAlert.`

16.26 SNMPAlertForward

Use this Knowledge Script to monitor and filter information in the Windows Event Log. If events are found that match the event types you select for monitoring, this script sends an alert in SNMP format.

On the **Actions** tab for this Knowledge Script, Action_SNMPTrap is selected by default.

16.26.1 Resource Object

BlackBerry Enterprise Server

16.26.2 Default Schedule

The default schedule is **Every 10 minutes**.

16.26.3 Setting Parameter Values

Set the following parameters as needed.

Description	How to Set It
Raise event if log entries found?	Set to **y** to raise events if Windows Event Log entries are found that match the selected type. Default is y.
Collect data for number and type of event log entries?	Set to **y** to collect data for charts and reports. If set to **y**, returns the number and type of events found in the Windows Event Log that match the event types you enabled. Default is n.
Separate log data from different sources into multiple events?	Set to **y** to separate event entries from the different log files into different data streams. If set to n, all the event entries matching your filtering criteria are placed in the same data stream and the data detail message may include event entries from multiple log sources. For example, if you are monitoring both the System and Application logs, set this parameter to **y** to track events in the System log separately from events in the Application log. Default is n.
Filter by log source: System, Security, Application	Specify the event log you want to monitor. You can specify multiple event logs separated by commas. For example, `System,Security,Application`. Default is `Application`.
Filter by event type: Error? Warning? Information? Success Audit? Failure Audit?	Set any or all of the event types to **y** to monitor for this type of event in the Windows Event Log. All defaults are y.
Filter by event source	Enter the appropriate string to monitor events generated by a particular source, such as `SQLExecutive` or `SNMP`. The Knowledge Script looks for matching entries in the **Source** field of each event. You can enter multiple strings separated by commas and include or exclude criteria using a colon (:). If you are only specifying include criteria, the colon is not necessary. Default value is `BlackBerry`.

Description	How to Set It
Filter by event category	Enter the appropriate string to monitor events generated in a particular category, such as Server or Logon. The Knowledge Script looks for matching entries in the **Category** field of each event. You can enter multiple strings separated by commas and include or exclude criteria using a colon (:). If you are only specifying include criteria, the colon is not necessary.
Filter by event ID	Enter an appropriate search string or event ID range (for example 100-2000) to monitor events with particular event IDs. The Knowledge Script looks for matching entries in the **Event** field of each event. You can enter multiple IDs and ranges separated by commas. For example: `1,2, 10-15, 202.` You can also include or exclude criteria using a colon (:). If you are only specifying include criteria, the colon is not necessary.
Filter by event user	Enter an appropriate search string, such as `<domain name>\<user name>`, to monitor for events associated with a particular user. The Knowledge Script looks for matching entries in the **User** field of each event. You can enter multiple strings separated by commas and include or exclude criteria using a colon (:). If you are only specifying include criteria, the colon is not necessary.
Filter by computer	Enter an appropriate search string, such as `netiqjonesr01`,to monitor events associated with a particular computer. The Knowledge Script looks for matching entries in the **Computer** field of each event. You can enter multiple strings separated by commas and include or exclude criteria using a colon (:). If you are only specifying include criteria, the colon is not necessary.
Filter by event description	Enter an appropriate search string, such as "`The SQLSERVERAGENT service terminated unexpectedly`". The Knowledge Script looks for matching entries in the **Description** field of each event. You can enter multiple strings separated by commas and include or exclude criteria using a colon (:). If you are only specifying include criteria, the colon is not necessary.
Maximum number of log entries per event	Specify the maximum number of entries to be recorded into each event detail message. If more entries are found in the log than can be placed in one event message, multiple events are raised to report all log entries. Default is 30 entries per event.
Event severity when matching log entries found	Set the event severity level, from 1 to 40, to indicate the importance of the event when log entries are found that match the criteria. Default is 8. You may want to adjust the severity depending on which log or type of event you are checking for.

16.27 SRPConnectionStatus

Use this Knowledge Script to monitor the percentage of uptime during the monitoring interval for the Server Routing Protocol (SRP) connection between the BlackBerry Server and the Research in Motion (RIM) infrastructure.

SRP makes a TCP/IP connection to the wireless network to transmit email messages to and from your wireless ISP. SRP is built on top of a TCP session between Port 3101 of the BlackBerry Enterprise Server and the IP address `srp.blackberry.net` or `srp.na.blackberry.net`.

If the percentage of uptime fails to meet the threshold, an event is raised.

NOTE: This script is unable to provide SRP connection status information more frequently than 1 sample per minute. Thus, if you change the default interval to less than Every 1 minute (for example, Every 20 seconds), the script only reports one data point every 20 seconds, but the data point represents the SRP connection status for the past minute.

16.27.1 Resource Object

BlackBerry Enterprise Server SRP connection

16.27.2 Default Schedule

The default interval is **Every 5 minutes**.

16.27.3 Setting Parameter Values

Set the following parameters as needed.

Description	How to Set It
Raise event if threshold not met?	Set to **y** to raise an event if the BlackBerry Server SRP connection is down or if WinSock error messages appear in the debug log. Default is y.
Collect data for SRP connection uptime?	Set to **y** to collect data for charts and events about the BlackBerry Server SRP connection. If set to **y**, this script returns data about the first ping test that was run and the associated status (success or failure), as well as the date and time of the ping test. Default is n.
Threshold – Minimum SRP connection uptime	Enter the lowest percentage of SRP connection uptime allowed before an event is raised. Enter a value from 0% to 100%. Default is 60%.
Event severity when threshold not met	Set the event severity level, from 1 to 40, to indicate the importance of the event. Default is 5.

16.28 SRPTest

Use this Knowledge Script to perform a Ping test of the BlackBerry Server SRP connection and display the result. An event is raised when the BlackBerry Server SRP connection returns a non-zero exit code (meaning that the connection couldn't be reached). The script can also raise an event if the ping test is successful.

For more information about the SRP connection, see the SRPConnectionStatus Knowledge Script.

NOTE: This Knowledge Script requires the BBSRPTest utility to run.

16.28.1 Resource Object

BlackBerry Server

16.28.2 Default Schedule

The default schedule is **Run once**.

16.28.3 Setting Parameter Values

Set the following parameters as needed.

Description	How to Set It
Raise event if test or job fails?	If set to n, this Knowledge Script raises an event when the Ping test to the BlackBerry Server SRP connection returns a non-zero exit code. If set to **y**, the script raises an event when the ping is successful. An event is always raised on script failure (if the ping test cannot be run). Default is y.
Collect data for SRP connection status?	Set to **y** to collect data for charts and reports. If set to **y**, returns the status of the BlackBerry Server SRP connection. Default is n.
BBSRPTest utility timeout	Set a timeout value from 1 to 120 seconds. The Knowledge Script keeps trying to locate the BBSRPTest utility (required to run the Ping test) until the timeout expires. Default is 20 seconds.
Path and filename for BBSRPTest utility	Enter the path and filename for the BlackBerry utility required to run the Ping test. Leave blank to use the BlackBerry default path.
Event severity: Ping succeeded	Set the event severity level, from 1 to 40, to indicate the importance of the event when the Ping test was successful. Default is 25.
Event severity: Ping returned non-zero exit code	Set the event severity level, from 1 to 40, to indicate the importance of the event when the Ping test returned a non-zero exit code. Default is 8.
Event severity: SRPTest command failed	Set the event severity level, from 1 to 40, to indicate the importance of the event when the script fails. Default is 40.

16.29 UserCountByServer

Use this Knowledge Script to report the number of users on a BlackBerry Server. Users are listed and sorted by their association with a messaging (Exchange) server. An event is raised if the total user count exceeds the threshold.

NOTE: This Knowledge Script requires the BBUserAdminClient executable to run.

16.29.1 Resource Object

BlackBerry Server

16.29.2 Default Schedule

The default schedule is **Every week**.

16.29.3 Setting Parameter Values

Set the following parameters as needed.

Description	How to Set It
Raise event if script succeeds?	Set to **y** to raise an event if the list of users is successfully generated. Default is n.
Raise event if threshold exceeded?	Set to **y** to raise an event if the threshold for number of users is exceeded. Default is y.
Collect data for users and servers?	Set to **y** to collect data for charts and reports. If set to **y**, returns a list of users of a BlackBerry Enterprise Server, sorted by their associated Exchange Server. Default is y.
Threshold – Maximum number of users	Enter the maximum total number of users allowed before an event is raised. Enter a value from 0 to 9000. Default is 300.
Path and filename for `BBUserAdminClient` executable	Enter the path and filename for the BlackBerry executable required to run the job. Leave blank to use the BlackBerry default path.
`BBUserAdminClient` executable timeout	Set a timeout value to determine how long the script attempts to reach the `BBUserAdminClient` executable. Enter a value from 1 to 120 seconds. Default is 10 seconds.
Event severity when threshold exceeded	Set the event severity level, from 1 to 40, to indicate the importance of the event. Default is 25.

16.30 UserList

Use this Knowledge Script to report all the users on a BlackBerry Server, and the total number of users on the BlackBerry Enterprise Server. By default, this script lists all the users and sorts them based on the Exchange Server they are associated with. You can also sort users alphabetically.

NOTE: This Knowledge Script requires the BBUserAdminClient executable to run.

16.30.1 Resource Object

BlackBerry Server

16.30.2 Default Schedule

The default schedule is **Every week**.

16.30.3 Setting Parameter Values

Set the following parameters as needed.

Description	How to Set It
Raise event if script succeeds?	Set to **y** to raise an event when the job completes successfully. Default is n.
Raise event if threshold exceeded?	Set to **y** to raises an event when the threshold is exceeded. Default is y.
Collect data for number of users?	Collects data about the number of users on the BlackBerry Server. Default is y.
Threshold – Maximum total number of users	Enter the maximum number of users of the BlackBerry Enterprise Server allowed before an event is raised. Enter a value from 0 to 900000. Default is 1500.
Threshold – Maximum users per BlackBerry Server	Enter the maximum number of users of a BlackBerry Server allowed before an event is raised. Enter a value from 0 to 900000. Default is 300.
Sort by Exchange Server?	Set to **y** to sort the list of users by each user's Exchange Server. Set to n to sort the list of users alphabetically. Default is y.
Path and filename for `BBUserAdminClient` executable	Enter the path and filename for the BlackBerry executable required to run the job. Leave blank to use the BlackBerry default path.
`BBUserAdminClient` executable timeout	Set a timeout value to determine how long the script attempts to reach the `BBUserAdminClient` executable, from 1 to 120 seconds. The default is 10 seconds.
Event severity when either threshold exceeded	Set the event severity level, from 1 to 40, to indicate the importance of the threshold-crossing event. Default is 25.

17 CallData Knowledge Scripts

AppManager provides the following Knowledge Scripts. From the Knowledge Script view of Control Center, you can access more information about any NetIQ-supported Knowledge Script by selecting it and clicking **Help**. In the Operator Console, click any Knowledge Script in the Knowledge Script pane and press **F1**.

Knowledge Script	What It Does
AddDataSource_CiscoCallMgr	Adds a Unified Communications Manager version 4.x Data Source and its associated Data Mart.
AddDataSource_CiscoCM	Adds a Unified Communications Manager Data Source (version 5 or later) and its associated Data Mart.
AddDataSource_H323RADIUS	Adds an H.323 RADIUS Data Source and its associated Data Mart.
CancelDataCollection	Cancels the current execution of data collection.
CCME_GetConfig	Retrieves configuration information from one or more Communications Manager Express devices.
ChangeReportingState	Changes the state of a Data Mart to be included in or excluded from reporting.
ChangeSchedule	Changes, deactivates, or reactivates the data collection schedule associated with a Data Source.
ConfigureCallTypes	Configures the rules by which the Call Data Analysis module classifies the types of calls each CDR contains.
DataCollectionStatus	Checks the status of the last data collection job performed against a Data Source.
ExecuteDataCollection	Performs on-demand data collection regardless of the collection schedule.
RemoveDataSource	Removes a Data Source and its associated Data Mart.
Report_CallAuthorization	Summarizes the number and duration of calls that used a Forced Authorization Code or a Client Matter Code.
Report_CallCompletionRate	Summarizes the completion rate of calls recorded with the selected Data Source. The call completion rate takes into account failed calls and abandoned calls.
Report_CallDetail_CiscoCallMgr	Summarizes details for calls that match criteria you specify for a selected Communications Manager. Call details can include time, calling number, and called number.
Report_CallDetail_H323Gateway	Summarizes details for calls that match criteria you specify for a selected gateway. Call details can include time, calling number, and called number.

Knowledge Script	What It Does
Report_CallFailureCauses	Analyzes the failure causes for calls that match criteria you specify.
Report_CallJitter	Categorizes calls as having good, acceptable, or poor jitter based on thresholds you specify.
Report_CallJitterLoss	Categorizes jitter loss percentages as good, acceptable, or poor based on thresholds you specify.
Report_CallMOS	Categorizes calls as having good, acceptable, or poor MOS or R-value based on thresholds you specify.
Report_CallPacketLoss	Categorizes calls as having good, acceptable, or poor packet loss based on thresholds you specify.
Report_CallQualityByPhone	Identifies the directory numbers that are experiencing problems with call quality, such as jitter and packet loss.
Report_CallSuccessRate	Summarizes the success rate of calls recorded with the selected Data Source. A successful call is determined by the call's disconnect cause code.
Report_CallTraffic	Summarizes call traffic based on call type.
Report_CallVolume	Summarizes the number and duration of calls recorded with the selected Data Source.
Report_CallVolumeEDS	Summarizes the number and duration of calls recorded with the selected Data Source.
Report_CCME_StatsByEPhone	Summarizes call statistics per Communications Manager Express ephone.
Report_CCME_Summary	Summarizes call statistics per Communications Manager Express gateway.
Report_FrequentlyCalledNumbers	Summarizes phone numbers called frequently during a specified time range.
Report_GatewayDialPeers	Summarizes call statistics for POTS and VoIP dial peers for the gateways included in the report.
Report_TrunkGroupByHour	Summarizes the trunk group or gateway volume by hour for the selected Communications Manager cluster or H.323 RADIUS Data Source.
Report_UnusedPhones	Creates a list of unused phones based on phones registered to the selected Data Source.

17.1 AddDataSource_CiscoCallMgr

Use this Knowledge Script to add a Cisco Unified Communications Manager version 4.x Data Source. With this script, you configure the Data Source and its collection schedule, the associated Data Mart, and access to the Data Warehouse. This script raises an event if a Data Source is added successfully, if the Data Mart server is inaccessible, if warnings are raised during an attempt to add a Data Source, and if a Data Source is not added.

This script creates the Data Mart, which is the container for all configuration and CDR information it gathers from the Data Source according to a schedule you determine.

AppManager needs to wait for the Communications Manager Publisher to receive the CDRs for completed calls from the Subscribers and push them into the CDR database. This buffer time is one hour. Therefore, after a call completes, you need to wait a minimum of one hour before the call is available for collection.

NOTE: After you run AddDataSource_CiscoCallMgr, press **F5** to refresh AppManager and display the other Knowledge Scripts available in the AppManager for Call Data Analysis module.

17.1.1 Prerequisite

Set Windows authentication permissions on the Communications Manager server and the Data Mart computer.

17.1.2 Resource Object

Call Data server

17.1.3 Default Schedule

By default, this script runs once.

17.1.4 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Configure Data Source	
Server name	Specify the computer name of the Communications Manager Publisher that will be the source of the CDR data.
SQL username (blank for Windows authentication)	Specify the SQL username required to access the Communications Manager Publisher. Leave this field blank to use Windows authentication.
SQL password	Specify the SQL password associated with the username you entered in the previous parameter.
Configure Data Source Schedule	

Parameter	How to Set It
Data source schedule type	Select the frequency with which you want the Data Mart to collect data from the Data Source: **Daily** or **Hourly**. The default is Daily.
Daily start time - Run daily at	If you selected **Daily** above, select the time of day at which you want data collected. Select from a list of hours based on a 24-hour clock. For instance, select 0100 for 1:00 AM. or select 1300 for 1:00 PM. The default is 0400. **Notes** • No matter what start time you select, AppManager needs to wait for the Communications Publisher to receive the CDRs for completed calls from the Subscribers and populate them into the CDR database. This buffer time is 1 hour. Therefore, after a call completes, you will need to wait a minimum of 1 hour before the call is available for collection. For instance, if you select 0400, data is collected up through 0300 to ensure no data is missed if the Communications Manager database is behind in writing its CDRs. • If you have multiple Data Sources, you may want to stagger your data collection times in order to balance the load on the Data Warehouse.
Hourly time interval - Run every n hours	If you selected **Hourly** above, select the interval at which you want data collected, such as every 2 hours or every 8 hours. The default is 12 hours. **Notes** • No matter what start time you select, AppManager needs to wait for the Communications Manager Publisher to receive the CDRs for completed calls from the Subscribers and populate them into the CDR database. This buffer time is 1 hour. Therefore, after a call completes, you will need to wait a minimum of 1 hour before the call is available for collection. For instance, perhaps you select every 2 hours, and the script collects data at 2 PM, 4 PM, and 6 PM. At 2 PM, data is gathered from 11 AM to 1 PM; at 4 PM, data is gathered from 1 PM to 3 PM; and at 6 PM, data is gathered from 3 PM to 5 PM to ensure no data is missed if the Communications Manager database is behind in writing its CDRs. • If you have multiple Data Sources, you may want to stagger your data collection times in order to balance the load on the Data Warehouse.
Data Collection	
Initially load n days of data	Specify the number of days' worth of accumulated data you want the Data Mart to collect during its first instance of data collection. The default is 7 days' worth of data.
Start data collection immediately?	Select **Yes** if you want the Data Mart to collect data immediately, rather than waiting for the first scheduled collection. The default is unselected. The first time the data collection job runs, it collects data for the past *n* days. When deciding whether to start data collection immediately, consider the impact the first, possibly large, data collection might have on your Communications Manager Publisher computer. You should perform the initial collection at an off-peak time.
Start SQL Server Agent if it is stopped?	Select **Yes** to start SQL Server Agent. SQL Server Agent must be running in order for data collection tasks to be performed. The default is unselected.
Keep data for n months	Specify the number of months' worth of collected data you want to keep in the database on the Data Mart. The data for the current month is always kept in the database. Therefore, if you choose to keep one month's worth of data, and it is December, the database will retain the data for December and November.

Parameter	How to Set It
Customize SQL Server Access Configuration For Data Mart?	Select **Yes** to customize the SQL Server access configuration for the Data Mart. You will then need to specify the name of the Data Mart server in the *Server name* parameter below. If you do not select **Yes**, the Data Mart database will be created on the same SQL Server instance as the Data Warehouse.
Server name	Specify the name of the server on which the Data Mart database will be created.
SQL username (blank for Windows authentication)	Specify the SQL username required to access the Data Mart server. Leave this field blank to use Windows authentication.
Database name (blank for default)	Specify a name for the Data Mart database. Leave this field blank to use the default Data Mart database name.
Customize SQL Server Access Configuration for Data Warehouse?	Select **Yes** if you want to customize the SQL username.
SQL username (blank for Windows authentication)	Specify the username required to access the SQL Server running on the Data Warehouse FROM the local NetIQ agent (`netiqmc` service) AND the SQL Server agent service running on the Data Mart computer. Leave this field blank to use Windows authentication. **NOTE:** If you leave this field blank, and the Data Mart is not located on the Data Warehouse computer, verify the `SQLSERVERAGENT` service on the Data Mart computer is running as a user that has access to the Data Warehouse database.
Event Notification	
Raise event if job succeeds?	Select **Yes** to raise an informational event when the AddDataSource job is successful. The default is Yes.
Event severity when job succeeds	Set the severity level, from 1 to 40, to reflect the importance of an event in which the AddDataSource job is successful. The default is 25.
Event severity when data mart server inaccessible	Set the severity level, from 1 to 40, to reflect the importance of an event in which the Data Mart server is inaccessible. The default is 10.
Event severity for warnings	Set the severity level, from 1 to 40, to reflect the importance of warnings raised during an attempt to add a Data Source. The default is 20.
Event severity when job fails	Set the severity level, from 1 to 40, to reflect the importance of an event in which the AddDataSource job fails. The default is 5.

17.2 AddDataSource_CiscoCM

Use this Knowledge Script to add a Cisco Unified Communications Manager (version 5 or later) Data Source. With this script, you configure the Data Source and its collection schedule, the associated Data Mart, and access to the Data Warehouse. This script raises an event if a Data Source is added successfully, if the Data Mart server is inaccessible, if warnings are raised during an attempt to add a Data Source, and if a Data Source is not added.

This script creates the Data Mart, which is the container for all configuration and CDR information it gathers from the Data Source according to a schedule you determine.

AppManager needs to wait for the Communications Manager primary server to push the CDRs to the Cisco CM managed object computer, and then for the CiscoCM_CDR_RetrieveCallRecords Knowledge Script to insert them into the Cisco CM supplemental database. To help ensure that all data is available, Call Data Analysis does not retrieve any call information within the past hour. Therefore, after a call completes, you need to wait a minimum of one hour before the call's CDR is available for collection.

NOTE: After you run AddDataSource_CiscoCM, press **F5** to refresh AppManager and display the other Knowledge Scripts available in the Call Data Analysis module.

17.2.1 Prerequisites

- Using the AppManager for Cisco Unified Communications Manager module, run the CiscoCM_SetupSupplementalDB Knowledge Script to create the Cisco CM supplemental database.
- Using the AppManager for Cisco Unified Communications Manager module, run the CiscoCM_CDR_RetrieveConfigData and CiscoCM_CDR_RetrieveCallRecords Knowledge Scripts to populate the supplemental database with configuration and call data from Communications Manager. After the supplemental database is populated, you can report on the data using the wide variety of Report Knowledge Scripts provided by AppManager for Call Data Analysis.

17.2.2 Resource Object

Call Data server

17.2.3 Default Schedule

By default, this script runs once.

17.2.4 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Configure Data Source	

Parameter	How to Set It
Primary Cisco Unified CallManager Server	Specify the computer name of the Communications Manager primary server that is the source of the CDA data stored in the Cisco CM supplemental database. The computer name you specify for this parameter must match the cluster name on the root CiscoCM object in the TreeView.
Supplemental database SQL Server	Specify the computer name of the SQL Server computer that houses the Cisco CM supplemental database.
SQL username	Specify the SQL username required to access the Cisco CM supplemental database. Leave this field blank to use Windows authentication.
Configure Data Source Schedule	
Data source schedule type	Select the frequency with which you want the Data Mart to collect data from the Data Source: **Daily** or **Hourly**. The default is Daily.
Daily start time - Run daily at	If you selected **Daily** above, select the time of day at which you want data collected. Select from a list of hours based on the 24-hour time system. For instance, select 0100 for 1:00 AM or select 1300 for 1:00 PM. The default is 0400. **Notes** • No matter what start time you select, AppManager needs to wait for the Communications Manager primary server to push the CDRs to the Cisco CM managed object computer, and then for the CDR_RetrieveCallRecords script to insert them into the Cisco CM supplemental database. This buffer time is one hour. Therefore, after a call completes, you will need to wait a minimum of one hour before the CDR is available for collection. For instance, if you select 0400, data is collected up through 0300 to ensure no data is missed if the primary server is behind in writing its CDRs. • If you have multiple Data Sources, you may want to stagger your data collection times in order to balance the load on the Data Warehouse.
Hourly time interval - Run every n hours	If you selected **Hourly** above, select the interval at which you want data collected, such as every 2 hours or every 8 hours. The default is 12 hours. **Notes** • No matter what start time you select, AppManager needs to wait for the Communications Manager primary server to push the CDRs to the Cisco CM managed object computer, and then for the CDR_RetrieveCallRecords script to insert them into the Cisco CM supplemental database. This buffer time is one hour. Therefore, after a call completes, you will need to wait a minimum of one hour before the CDR is available for collection. For instance, if you select 0400, data is collected up through 0300 to ensure no data is missed if the primary server is behind in writing its CDRs. • If you have multiple Data Sources, you may want to stagger your data collection times in order to balance the load on the Data Warehouse.
Data Collection	
Initially load n days of data	Specify the number of days' worth of accumulated data you want the Data Mart to collect during its first instance of data collection. The default is 7 days' worth of data.

Parameter	How to Set It
Start data collection immediately?	Select **Yes** if you want the Data Mart to collect data immediately, rather than waiting for the first scheduled collection. The default is unselected. The first time the data collection job runs, it collects data for the past *n* days. When deciding whether to start data collection immediately, consider the impact the first, possibly large, data collection might have on the computer that houses the Cisco CM supplemental database. You should perform the initial collection at an off-peak time.
Start SQL Server Agent if it is stopped?	Select **Yes** to start SQL Server Agent. SQL Server Agent must be running in order for data collection tasks to be performed. The default is unselected.
Keep data for n months	Specify the number of months' worth of collected data you want to keep in the database on the Data Mart. The data for the current month is always kept in the database. Therefore, if you choose to keep 1 month's worth of data, and it is December, the database will retain the data for December and November.
Customize SQL Server Access Configuration For Data Mart?	Select **Yes** to customize the SQL Server access configuration for the Data Mart. You will then need to specify the name of the Data Mart server in the *Server name* parameter below. If you do not select **Yes**, the Data Mart database will be created on the same SQL Server instance as the Data Warehouse.
Server name	Specify the name of the server on which the Data Mart database will be created.
SQL username	Specify the SQL username required to access the Data Mart server. Leave this field blank to use Windows authentication.
Database name (blank for default)	Specify a name for the Data Mart database. Leave this field blank to use the default Data Mart database name.
Customize SQL Server Access Configuration for Data Warehouse?	Select **Yes** if you want to customize the SQL username.
SQL username (blank for Windows authentication)	Specify the username required to access the SQL Server running on the Data Warehouse FROM the local NetIQ agent (`netiqmc` service) AND the SQL Server agent service running on the Data Mart computer. Leave this field blank to use Windows authentication. **NOTE:** If you leave this field blank, and the Data Mart is not located on the Data Warehouse computer, verify the `SQLSERVERAGENT` service on the Data Mart computer is running as a user that has access to the Data Warehouse database.
Event Notification	
Raise event if job succeeds?	Select **Yes** to raise an informational event when the AddDataSource job is successful. The default is Yes.
Event severity when job succeeds	Set the severity level, from 1 to 40, to reflect the importance of an event in which the AddDataSource job is successful. The default is 25.
Event severity when data mart server inaccessible	Set the severity level, from 1 to 40, to reflect the importance of an event in which the Data Mart server is inaccessible. The default is 10.
Event severity for warnings	Set the severity level, from 1 to 40, to reflect the importance of warnings raised during an attempt to add a Data Source. The default is 20.
Event severity when job fails	Set the severity level, from 1 to 40, to reflect the importance of an event in which the AddDataSource job fails. The default is 5.

17.3 AddDataSource_H323RADIUS

This script creates the Data Mart, which is the container for all configuration and CDR information it gathers from the Data Source according to a schedule you determine.

The H.323 RADIUS Data Source is the log (flat) files written by the IAS/RADIUS server when it receives call detail records generated by Cisco H.323 gateways and Communications Manager Express routers.

Cisco Communications Manager Express views the IP phones connected to it as virtual voice ports (EFXS) and generates telephony call legs to and from these phones. Therefore, call quality information is not available for a call from Communications Manager Express phones for which the call remains on Communications Manager Express or goes directly to the PSTN.

This script raises an event if a Data Source is added successfully, if the Data Mart server is inaccessible, if warnings are raised during an attempt to add a Data Source, and if a Data Source is not added.

You can re-run this Knowledge Script to change parameter settings, such as log file archiving. If you do so, you need to complete all parameters, not just those you are changing.

NOTE: After you run AddDataSource_H323RADIUS, press **F5** to refresh AppManager and display the other Knowledge Scripts available in the Call Data Analysis module.

17.3.1 Changing RADIUS Log Folder or Archive Settings

When you add a Data Source, you specify whether to archive RADIUS logs after processing. In addition, you indicate the location of the RADIUS logs and the location of the archive folder.

To change any of these settings for a Data Source you already added, rerun AddDataSource_H323RADIUS and complete all parameters, including those for which the setting is not changing:

- *Folder containing IAS RADIUS logs*. Use this parameter to specify the location on the Data Mart of the folder that houses the IAS RADIUS logs. This location is the one you set up when you configured IAS.
- *Archive RADIUS logs after processing?* Set this parameter to **Yes** if you want to archive the RADIUS logs after their data has been processed. If you set this parameter to **Yes**, you must use the *Archive folder* parameter to specify the location of the archive folder.
- *Archive folder*. Use this parameter to specify the location on the Data Mart of the folder in which you want to archive the processed RADIUS logs.

NOTE: If you rerun AddDataSource_H323RADIUS, all parameters are updated, not only the three discussed above. Therefore, if you originally added your Data Source with any non-default parameter values, ensure you set those parameters correctly when you run the script to change archive or log information.

17.3.2 Reviewing Call Quality Metrics for Gateways and Routers

Cisco H.323 gateways provide call quality information for the VoIP legs of a call. Using this information, AppManager calculates additional quality metrics.

MOS

The Mean Opinion Score is an overall score representing the quality of a call. The MOS is a number between 1 and 5. A MOS of 5 is excellent; a MOS of 1 is unacceptably bad. The MOS is calculated based on measured items plus jitter buffer size.

R-value

Can be mapped to an estimated MOS. R-values range from 100 (excellent) to 0 (poor).

Jitter loss

Calculated from the number of received and discarded packets. Discarded packets are those that arrive too early or too late to be stored in the jitter buffer.

Packet loss

Calculated from the number of received and lost packets.

Delay

One-way delay approximated by dividing the round-trip delay value (from the RADIUS record) by two.

Voice quality

The Cisco IOS software (which is installed on the router on which the H.323 gateway resides) measures call quality based on ITU G.113, which defines the term Calculated Planning Impairment Factor (ICPIF), a calculation based on network delay and packet loss. ICPIF yields a single value that can be used to gauge network impairment. ITU G.113 provides the following interpretations of specific ICPIF values:

- 5 - Very good
- 10 - Good
- 20 - Adequate
- 30 - Limiting case
- 45 - Exceptional limiting case
- 55 - Customers likely to react strongly

NOTE: Use the Report_CallDetail_H323Gateway script to see the ICPIF values for individual calls.

17.3.3 Resource Object

Call Data server

17.3.4 Default Schedule

By default, this script runs once.

17.3.5 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Configure Data Source	
Folder containing IAS RADIUS logs	Specify the location on the Data Mart of the folder that houses the IAS RADIUS logs. This location is the one you set up when you configured IAS.
Configure Data Source Schedule	
Data source schedule type	Select the frequency with which you want the Data Mart to collect data from the Data Source: **Daily** or **Hourly**. The default is Daily.

Parameter	How to Set It
Daily start time - Run daily at	If you selected **Daily** above, select the time of day at which you want data collected. Select from a list of hours based on a 24-hour clock. For instance, select 0100 for 1:00 A.M. or select 1300 for 1:00 P.M. The default is 0400. **NOTE:** If you have multiple Data Sources, you may want to stagger your data collection times in order to balance the load on the Data Warehouse.
Hourly time interval - Run every n hours	If you selected **Hourly** above, select the interval at which you want data collected, such as every 2 hours or every 8 hours. The default is 12 hours. **NOTE:** If you have multiple Data Sources, you may want to stagger your data collection times in order to balance the load on the Data Warehouse.
Data Collection	
Archive RADIUS logs after processing?	Select **Yes** to archive the RADIUS logs after their data has been processed. The default is unselected. If you set this parameter to Yes, specify the location of the archive folder in the *Archive folder* parameter.
Archive folder	Specify the location on the Data Mart of the folder in which you want to archive the processed RADIUS logs.
Start data collection job immediately?	Select **Yes** if you want the Data Mart to collect data immediately, rather than waiting for the first scheduled collection. The default is unselected.
Start SQL Server Agent if it is stopped?	Select **Yes** to start SQL Server Agent. SQL Server Agent must be running in order for data collection tasks to be performed. The default is unselected.
Keep data for n months	Specify the number of months' worth of collected data you want to keep in the database on the Data Mart. The data for the current month is always kept in the database. Therefore, if you choose to keep 1 month's worth of data, and it is December, the database will retain the data for December and November.
Customize SQL Server Access Configuration For Data Mart?	Select **Yes** to customize the SQL Server access configuration for the Data Mart. You will then need to specify the name of the Data Mart server in the *Server name* parameter below. If you do not select **Yes**, the Data Mart database will be created on the same SQL Server instance as the Data Warehouse.
Server name	Specify the name of the server on which the Data Mart database will be created.
SQL username	Specify the SQL username required to access the Data Mart server. Leave this field blank to use Windows authentication.
Database name (blank for default)	Specify a name for the Data Mart database. Leave this field blank to use the default Data Mart database name.
Customize SQL Server Access Configuration for Data Warehouse?	Select **Yes** if you want to customize the SQL username.
SQL username	Specify the username required to access the SQL Server running on the Data Warehouse FROM the local NetIQ agent (`netiqmc` service) AND the SQL Server agent service running on the Data Mart computer. Leave this field blank to use Windows authentication. **NOTE:** If you leave this field blank, and the Data Mart is not located on the Data Warehouse computer, verify the `SQLSERVERAGENT` service on the Data Mart computer is running as a user that has access to the Data Warehouse database.

Parameter	How to Set It
Event Notification	
Raise event if job succeeds?	Select **Yes** to raise an informational event when the AddDataSource job is successful. The default is Yes.
Event severity when job succeeds	Set the severity level, from 1 to 40, to reflect the importance of an event in which the AddDataSource job is successful. The default is 25.
Event severity when data mart server inaccessible	Set the event severity level, from 1 to 40, to reflect the importance of an event in which the Data Mart server is inaccessible. The default is 10.
Event severity for warnings	Set the event severity level, from 1 to 40, to reflect the importance of warnings raised during an attempt to add a Data Source. The default is 20.
Event severity when job fails	Set the event severity level, from 1 to 40, to reflect the importance of an event in which the AddDataSource job fails. The default is 5.

17.4 CancelDataCollection

Use this Knowledge Script to stop any data collection currently being performed. If data is not currently being collected, this script takes no action. Running this script does not affect the data collection schedule.

This script raises an event if data cancellation succeeds or fails, and if data is not being collected.

17.4.1 Resource Objects

Call Data CallManager object

Call Data H.323 RADIUS object

Call Data CiscoCM object

17.4.2 Default Schedule

By default, this script runs once.

17.4.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Event Notification	
Event severity when cancellation succeeds	Set the severity level, from 1 to 40, to reflect the importance of an event in which cancellation succeeds. The default is 25.
Event severity when no data collection to cancel	Set the severity level, from 1 to 40, to reflect the importance of a situation in which there is no data collection to cancel. The default is 25.
Event severity when cancellation fails	Set the severity level, from 1 to 40, to reflect the importance of an event in which cancellation fails. The default is 5.

17.5 CCME_GetConfig

Use this Knowledge Script to retrieve configuration data from one or more Communications Manager Express devices and deposit that data into SQL tables located in the Data Mart. By default, this script retrieves configuration data for all Communications Manager Express devices that have sent RADIUS records to the Data Source and have EFXS (virtual voice) ports through which ephones are connected. However, you can choose to limit the devices by using the "Include" and "Exclude" parameters.

This script raises an event if configuration data is retrieved and deposited successfully, if no Communications Manager Express devices are found, if the retrieve and/or deposit processes fail for any Communications Manager Express device, or if the entire GetConfig job fails for any reason.

The collected configuration data helps AppManager associate the virtual voice port from the RADIUS records with the IP address and device name of the associated Communications Manager Express phone. The data is also required by the Report_CCME_StatsByEPhone and Report_UnusedPhones Knowledge Scripts.

17.5.1 Prerequisites

- Run AddDataSource_H323RADIUS.
- Configure your AXL passwords in AppManager Security Manager. AVVID XML Layer (AXL), a Cisco application programming interface (API), enables Communications Manager Express to access the Communications Manager Express HTTP server.

  If your AXL password information is the same for all Communications Manager Express devices, complete the following procedure once. If your AXL password information is different for different devices, complete the following procedure once for each different password.

  On the Custom tab in AppManager Security Manager, complete the following fields:

Field	Description
Label	`CiscoCME`
Sub-label	• For a single Communications Manager Express device, type the name of the device. • For all Communications Manager Express devices, type `default`. **NOTE:** If you type a single device name, ensure the name is an exact match to the gateway name (`h323-gw-id`) or the `NAS-IP-Address` from the RADIUS records. If you are unsure of the gateway name or NAS IP address, run Discovery_CallDataAnalysis after IAS logs have been processed. The name of the gateway will appear in the TreeView pane under the H.323 Data Source object. To see the NAS IP address, click on the gateway name, and then click the **Details** tab.
Value 1	Type the AXL password you configured using the "og password" IOS command on the router. If you did not configure an AXL password, type the "Router privilege mode" password.
Extended application support	Enable to encrypt the AXL password. Do not leave this option unselected.

17.5.2 Resource Object

Call Data H.323 RADIUS object

17.5.3 Default Schedule

By default, this script runs once every day.

17.5.4 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Include only these CallManager Express devices	Specify which Communications Manager Express devices (gateways) to poll for configuration data. Use this parameter to limit the number of "learned" devices that are polled or to poll devices that are not yet "learned." A learned device is one that has already sent RADIUS records to the Data Source. If you specify one or more unlearned devices, you must specify the gateway name that matches the name returned in the `h323_gw_id` field of the RADIUS record. Leave this parameter blank to poll all learned Communications Manager Express devices for configuration data. Separate the names of multiple devices with a comma and no space.
Exclude these CallManager Express devices	Specify which Communications Manager Express devices (gateways) to exclude from polling. Separate the names of multiple devices with a comma and no space. Leave this parameter blank to exclude no devices.
Event Notification	
Raise event if retrieve/deposit process succeeds?	Select **Yes** to raise an event if the configuration data is retrieved and deposited (into the Data Mart SQL tables) successfully. The default is Yes.
Event severity when retrieve/deposit process succeeds	Set the severity level, from 1 to 40, to reflect the importance of an event in which configuration data is retrieved and deposited successfully. The default is 25.
Raise event if no CallManager Express devices found?	Select **Yes** to raise an event if AppManager cannot find any Communications Manager Express devices to poll for configuration data. The default is Yes.
Event severity when no CallManager Express devices found	Set the severity level, from 1 to 40, to reflect the importance of an event in which AppManager can find no Communications Manager Express devices to poll. The default is 15.
Event severity when retrieve/deposit process fails	Set the severity level, from 1 to 40, to reflect the importance of an event in which any part of the retrieve and deposit process fails for any individual Communications Manager Express device. This event is raised if the retrieve/deposit process fails for one or more Communications Manager Express devices, but succeeds for others. The default is 10.

Parameter	How to Set It
Event severity when job fails	Set the severity level, from 1 to 40, to reflect the importance of an event in which the GetConfig Knowledge Script job fails.

17.6 ChangeReportingState

Call Data Analysis reports make use of SQL views that include all Data Marts associated with your Data Sources. The Call Data Analysis reports fail if even one of the Data Marts in a SQL view cannot be accessed from the Data Warehouse.

If you know a particular Data Mart cannot be accessed for some reason (such as being down for maintenance), use this Knowledge Script to exclude that Data Mart from reporting. Then, when the Data Mart is ready, use this Knowledge Script to change its reporting status so it is once again included in reporting.

NOTE: Highlight the Data Source object in the TreeView of the Operator Console to see the reporting state displayed on the **Details** tab. After changing the reporting state, you may need to click on a different object and then click back on the Data Source object to verify the change in the reporting state.

17.6.1 Resource Objects

Call Data CallManager object

Call Data H.323 RADIUS object

Call Data CiscoCM object

17.6.2 Default Schedule

By default, this script runs once.

17.6.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Change Reporting State	
Select the reporting state for the Data Mart	Use this parameter to change whether a Data Mart is included in reporting. Select **Include** to include the Data Mart associated with the Data Source on which you dropped this script. Select **Exclude** to exclude the Data Mart associated with the Data Source on which you ran this script.
Event Notification	
Event severity when reporting state change succeeds	Set the severity level, from 1 to 40, to indicate the importance of an event in which a change in the reporting state succeeds. The default is 25.
Event severity when reporting state change fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which a change in the reporting state fails, most likely as the result of a SQL failure. The default is 5.

17.7 ChangeSchedule

Use this Knowledge Script to change, deactivate, or reactivate the data collection schedule associated with a Data Source. This script raises an event when a schedule change succeeds or fails, or when a schedule cannot be changed.

To change other data collection settings, such as how many days' worth of data to load, or how many months' worth of data to keep, run the appropriate AddDataSource Knowledge Script. You can run an AddDataSource Knowledge Script even after you added the Data Source.

17.7.1 Resource Objects

Call Data CallManager object

Call Data H.323 RADIUS object

Call Data CiscoCM object

17.7.2 Default Schedule

By default, this script runs once.

17.7.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Manage Schedule	
Select Schedule Action	Select the action you want this script to perform: • **Change Schedule**. This default selection allows you to change the schedule type, the collection start time, or the hourly collection interval. If you select Change Schedule, you must set one or more of the parameters in the **Change Schedule Parameters** folder. • **Deactivate Schedule**. Deactivates the data collection schedule. Data collection will not resume until you run this script again and select **Reactivate Schedule**. • **Reactivate Schedule**. Reactivates the data collection schedule and collects data at the next scheduled instance. The Data Mart will collect all data that has accrued since the last collection instance.
Change Schedule Parameters	
Data source schedule type	Select the frequency with which you want the Data Mart to collect data from the Data Source: **Daily** or **Hourly**. The default is Daily.
Daily start time - Run daily at	If you selected **Daily** above (or when you added the Data Source), select the time of day at which you want data collected. Select from a list of hours based on a 24-hour clock. For instance, select 0100 for 1:00 AM or select 1300 for 1:00 PM. The default is 0400.

Parameter	How to Set It
Hourly time interval - Run every n hours	If you selected **Hourly** above (or when you added the daily source), select the interval at which you want data collected, such as every 2 hours or every 8 hours. The default is 12 hours.
Event Notification	
Event severity when schedule change succeeds	Set the severity level, from 1 to 40, to reflect the importance of an event in which the schedule change succeeds. The default is 25.
Event severity when schedule change fails	Set the severity level, from 1 to 40, to reflect the importance of an event in which the schedule change fails. The default is 5.
Event severity when schedule cannot be changed	Set the severity level, from 1 to 40, to reflect the importance of a situation in which the changes you have selected already exist in the schedule. The default is 25.

17.8 ConfigureCallTypes

Use this Knowledge Script to configure the rules by which the Call Data Analysis module classifies the types of calls each CDR contains, such as configuring gateway rules that identify certain calls going through the gateway as local rather than long distance.

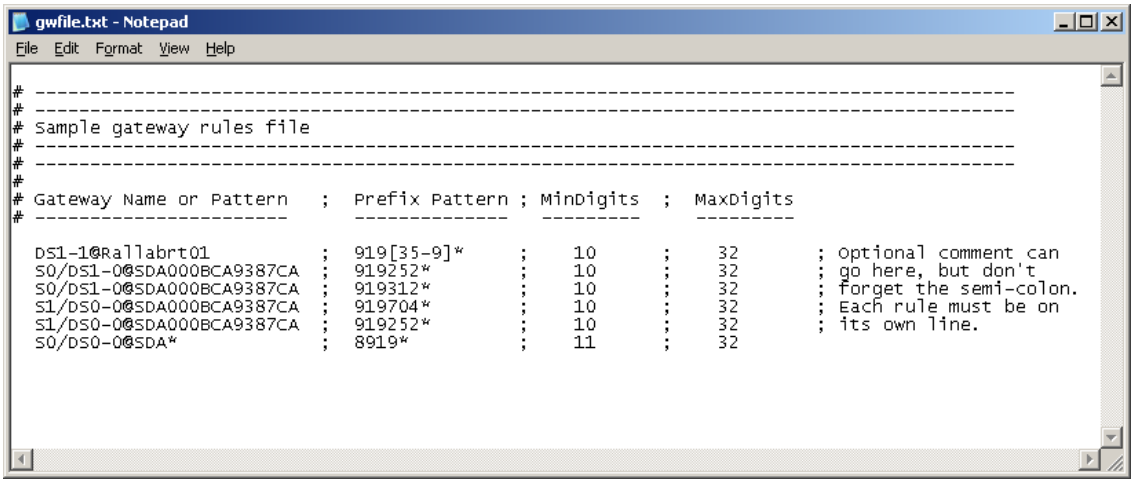
You specify the name of the gateway and the prefixes that indicate a call is local. The prefix is not limited to an area code, which helps in situations in which numbers within the same area code are treated differently. For example, if 919-767-0295 is a local call, but 919-252-7463 is long distance, specify 9197* or 919767* as the prefix pattern.

If all calls within an area code are to be classified as local, specify a "*" as the gateway pattern and specify 919* as the prefix pattern.

Because you may need to specify many gateways or gateway devices, you can create a file that contains a list of all gateways and devices. If you create a list, you do not have to specify each gateway and device separately in the *Gateway names or patterns* parameter. You can use the *Full path to gateway rules file* parameter to point to the file you created. You need to save this file on the Data Warehouse computer, *not* the Data Mart server.

You must create the gateway rules file in the following format:

- A number sign (#) in the first column identifies a comment line.
- The rule is four fields separated by semicolons (;).
- The first field is the Gateway Name or Pattern.
- The second field is the Prefix Pattern that identifies a local call.
- The third field is the minimum number of digits that must be found in order for a call to be classified as a gateway call.
- The fourth field is the maximum number of digits that can be found in order for a call to be classified as a gateway call.



You also use this script to specify external access codes. Most systems require an access code to be dialed before routing a call to a remote or local gateway. If you specify an access code, Call Data Analysis will remove it before determining a call's classification. Keep this in mind when specifying other parameters. For example, if you want to add 1877* to the Toll Free call rules, and your external access code is 9, you need to add 1877* (not 91877*) as a pattern in the *Configure toll free call rules* parameters.

This script raises an event when the job succeeds or fails, when the Data Mart server is inaccessible, and when warnings are raised during an attempt to configure call types.

Resetting the ConfigureCallTypes Script

You can use SQL Query Analyzer on the Data Mart computer to return the parameters in the ConfigureCallTypes script to their original default values. In the **Database Selection** drop list in the Query Analyzer interface, select the Data Mart database for which you want to reset the call type rules. In the Query window, type the following command: `exec dbo.SetCallTypeDefaults`. To verify the call type rules have been reset, issue the following command in the Query window:

```
select * From CallTypeRules
```

Reviewing Call Classification Types

Use the ConfigureCallTypes Knowledge Script to configure the rules by which the Call Data Analysis module classifies the types of calls each CDR contains. The following table describes each classification type.

Classification Type	Description
Internal	Intracluster call that originated in the network and ended in the same network (no gateway was used). Both the called and calling numbers are internal numbers.
On-net	Call in which both the calling and called numbers are internal, and either the originating or destination device is a gateway.
Incoming	Call that originated outside of the network and whose called number is an internal number.
Conference bridge	Call whose destination device is a conference bridge.
Voice mail	Call whose destination device is a voice mail device.
Local	Call whose destination device is a gateway, and whose called number is not an internal number and does not have an area code (or includes one of the local area codes).
Tandem - local	Local call that originated outside of the network.
Long distance	Call whose destination device is a gateway, and whose called number is not an internal number and has an area code that is not one of the local area codes.
Tandem - long distance	Long distance call that originated outside of the network.
International	Call whose destination device is a gateway, and whose called number begins with the international access code.
Tandem - international	International call that originated outside of the network.
Tandem	If the Tandem Rule is “collapse,” this category is a combination of the Tandem - local, Tandem - long distance, and Tandem - international categories.
Service	Call to a service, usually three digits, such as 411 (Directory Service).
Emergency	Call to an emergency service, such as 911.
Toll free	Long distance call that is toll free, such as 1-800 calls.
Other	User-defined rule.
Unknown	Call that does not match any of the other categories.

Resource Objects

Call Data CallManager object

Call Data H.323 RADIUS object

Call Data CiscoCM object

Default Schedule

By default, this script runs once.

Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Configure Call Classification Rules	
Configure External Access Code	
Action	Select whether you want to **Replace**, **Remove All**, or make **No Change** regarding the external access code. For more information, see Action Parameter. The default is No Change.
External access code	Specify the access code your system requires for routing calls to a remote or local gateway. The default is 9.
Configure Internal Call Rules	
Action	Select whether you want to **Append**, **Replace**, **Remove All**, or make **No Change** regarding internal call rules. For more information, see Action Parameter. The default is No Change.
Internal numbers or patterns	Specify numbers or patterns that identify an internal call. Separate multiple entries with a semicolon (;). The default is [2-7]XX;[1-8]XXX;[1-8]XXXX;[1-8]XXXXX.
Minimum digits dialed for internal calls	Specify the minimum number of digits that must be found in order for a call to be classified as internal. The default is 3.
Maximum digits dialed for internal calls	Specify the maximum number of digits that must be found in order for a call to be classified as internal. The default is 6.
Configure International Call Rules	
Action	Select whether you want to **Append**, **Replace**, or make **No Change** regarding international call rules. For more information, see Action Parameter. The default is No Change.
International dialing prefixes	Specify the prefix that identifies an international call. Do not include the external access code. The default prefixes are 011*;00*;010*. For more information, see Wildcard Characters.
Minimum digits dialed for international calls	Specify the minimum number of digits that must be found in order for a call to be classified as international. The default is 10.
Maximum digits dialed for international calls	Specify the maximum number of digits that must be found in order for a call to be classified as international. The default is 32. **NOTE:** You can specify a large value to indicate there is no maximum limit.

Parameter	How to Set It
Configure Local Call Rules	
Action	Select whether you want to **Replace** or make **No Change** regarding local call rules. For more information, see Action Parameter. The default is No Change.
Minimum digits dialed for local calls	Specify the minimum number of digits that must be found in order for a call to be classified as local. The default is 7.
Maximum digits dialed for local calls	Specify the maximum number of digits that must be found in order for a call to be classified as local. The default is 10.
Configure Long Distance Call Rules	
Action	Select whether you want to **Replace** or make **No Change** regarding long distance call rules. For more information, see Action Parameter. The default is No Change.
Minimum digits dialed for long distance calls	Specify the minimum number of digits that must be found in order for a call to be classified as long distance. The default is 10.
Maximum digits dialed for long distance calls	Specify the maximum number of digits that must be found in order for a call to be classified as long distance. The default is 32. **NOTE:** You can specify a large value to indicate there is no maximum limit.
Configure Long Distance Access Code	
Action	Select whether you want to **Remove All**, **Replace**, or make **No Change** regarding the long distance access code. For more information, see Action Parameter. The default is No Change.
Long distance dialing prefix	Specify the access code your system requires for routing long distance calls. The default is 1.
Configure Gateway Rules	
Action	Select whether you want to **Append**, **Remove All**, **Replace**, or make **No Change** regarding the gateway rules. For more information, see Action Parameter. The default is No Change.
Gateway Rules File	
Full path to gateway rules file	Type the fully qualified path to a file on the Data Warehouse computer that contains a list of gateway names, patterns, and prefixes that identify local calls.
Severity - File I/O problems	Set the severity level, from 1 to 40, to reflect the importance of an event in which the gateway rules file is inaccessible. The rules file could be unreachable for a number of reasons, including an incorrect fully qualified file path. The default is 20.
Gateway names or patterns	Specify the names or patterns of gateways to check. Use wildcards if necessary and use semicolons (;) to separate multiple entries. For more information, see "Wildcard Characters" on page 716. If you specified a gateway rules file, you do not need to complete this parameter, but you can if you have rules to add in addition to what is in the rules file.
Prefix patterns	Specify numbers or patterns that identify local calls. Use semicolons (;) to separate multiple entries. If you specified a gateway rules file, you do not need to complete this parameter, but you can if you have rules to add in addition to what is in the rules file.

Parameter	How to Set It
Minimum digits dialed for these patterns	Specify the minimum number of digits that must be found in order for a call to fit the gateway rules. The default is 7.
Maximum digits dialed for these patterns	Specify the maximum number of digits that must be found in order for a call to fit the gateway rules. The default is 32. **NOTE:** You can specify a large value to indicate there is no maximum limit.
Configure Service Call Rules	
Action	Select whether you want to **Append**, **Remove All**, **Replace**, or make **No Change** regarding service calls. For more information, see Action Parameter. The default is No Change.
Service numbers or patterns	Specify the numbers or patterns that identify a service call. Use semicolons (;) to separate multiple entries. The default is [2-8]11.
Minimum digits dialed for service calls	Specify the minimum number of digits that must be found in order for a call to be classified as service. The default is 3.
Maximum digits dialed for service calls	Specify the maximum number of digits that must be found in order for a call to be classified as service. The default is 3.
Configure Toll Free Call Rules	
Action	Select whether you want to **Append**, **Remove All**, **Replace**, or make **No Change** regarding toll free calls. For more information, see Action Parameter. The default is No Change.
Toll free numbers or patterns	Specify the numbers or patterns that identify a toll free call. Use semicolons (;) to separate multiple entries. The default is 1800*;1855*;1866*;1877*;1888. For more information, see Wildcard Characters.
Minimum digits dialed for toll free calls	Specify the minimum number of digits that must be found in order for a call to be classified as toll free. The default is 7.
Maximum digits dialed for toll free calls	Specify the maximum number of digits that must be found in order for a call to be classified as toll free. The default is 32. **NOTE:** You can specify a large value to indicate there is no maximum limit.
Configure Emergency Call Rules	
Action	Select whether you want to **Append**, **Remove All**, **Replace**, or make **No Change** regarding emergency calls. For more information, see Action Parameter. The default is No Change.
Emergency numbers or patterns	Specify the numbers or patterns that identify an emergency call. Use semicolons (;) to separate multiple entries. The default is 911.
Minimum digits dialed for emergency calls	Specify the minimum number of digits that must be found in order for a call to be classified as emergency. The default is 3.
Maximum digits dialed for emergency calls	Specify the maximum number of digits that must be found in order for a call to be classified as emergency. The default is 3.
Configure Other Call Rules	
Action	Select whether you want to **Append**, **Remove All**, **Replace**, or make **No Change** regarding other calls. For more information, see Action Parameter.The default is No Change.
Other numbers or patterns	Specify the numbers or patterns that identify other calls. Use semicolons (;) to separate multiple entries.

Parameter	How to Set It
Minimum digits dialed for other calls	Specify the minimum number of digits that must be found in order for a call to be classified as other. The default is 3.
Maximum digits dialed for other calls	Specify the maximum number of digits that must be found in order for a call to be classified as other. The default is 24. **NOTE:** You can specify a large value to indicate there is no maximum limit.
Configure Tandem Rule	
Action	Select whether you want to **Remove All** or make **No Change** regarding the tandem rule. For more information, see Action Parameter. The default is No Change. If you remove the tandem rule, calls are not classified as tandem. In other words, all Tandem-Local, Tandem-Long Distance, and Tandem-International calls will be classified simply as Local, Long Distance, and International.
Tandem rule	Set the tandem rule as follows: • Select **Expand** to classify tandem calls as Tandem-Local, Tandem-Long Distance, and Tandem-International. The default is Expand. • Select **Collapse** to classify tandem calls as Tandem, and not split into the three sub-categories.
Update Fact Data	
Update existing fact data using updated rules?	Select **Yes** to instruct the Data Mart to update data immediately using the new or revised rules. This update does not affect the next scheduled collection.
Update previous n days of data	Specify the number of days' worth of accumulated data you want the Data Mart to update using the new or revised rules. The default is 7 day's worth of data.
Update all data?	Select **Yes** to instruct the Data Mart to update all of the data in the database. **Caution** You may have several months' or years' worth of accumulated data. Select this option only with the understanding that the process of updating a lot of data can be lengthy.
Event Notification	
Event severity when job succeeds	Set the severity level, from 1 to 40, to reflect the importance of an event in which the ConfigureCallTypes job succeeds. The default is 25.
Event severity when data mart server inaccessible	Set the severity level, from 1 to 40, to reflect the importance of an event in which the Data Mart server is inaccessible. The default is 10.
Event severity for warnings	Set the severity level, from 1 to 40, to reflect the importance of warnings raised during an attempt to configure call types. The default is 20.
Event severity when job fails	Set the severity level, from 1 to 40, to reflect the importance of an event in which the ConfigureCallTypes job fails. The default is 5.

17.8.1 Action Parameter

In the list of parameters, each rule and access code folder contains an Action parameter you set to indicate the action you want to take regarding the rules and access codes for each call type. The following table describes the Action options you can select.

Action Parameter Option	Description
No Change	Indicates you do not want to change the rule or access code for this call type.
Append	Appends the new rule to any existing rules for this call type.
Replace	Replaces all existing rules with the new rule you are creating for this call type.
Remove All	Removes all existing rules for this call type. If you select this option, the Call Data Analysis module does not classify calls of this type.

17.8.2 Wildcard Characters

When specifying number patterns in parameters, you can use any of the following wildcards and special characters.

Character	Description	Example
X	The X wildcard matches any single digit in the range of 0 through 9.	70XXX matches numbers in the range of 70000 through 70999.
*	The asterisk (*) wildcard matches one or more digits in the range of 0 through 9. **NOTE:** You can use an exclamation point (!) in place of an asterisk.	011* matches any number beginning with 011, such as 011447968587655.
[ ]	Square brackets ([ ]) enclose a range of values.	[4578]11 matches 411, 511, 711, and 811.
-	The hyphen (-) can be used within square brackets to indicate a sequential range of values.	[4-8]11 matches 411, 511, 711, and 811.

17.9 DataCollectionStatus

Use this Knowledge Script to check the status of the last data collection job performed against a Data Source. This script raises an event when the data collection attempt fails, when the data collection job is cancelled, or when the DataCollectionStatus job itself fails.

17.9.1 Resource Objects

Call Data CallManager object

Call Data H.323 RADIUS object

Call Data CiscoCM object

17.9.2 Default Schedule

By default, this script runs daily.

17.9.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Show history for previous n jobs	Specify the number of previous data collection jobs for which you want to view the status. The default is 7.
Show job steps?	Select **Yes** to enable an event to display information about each of the eight individual steps in a data-collection job. Accept the default (unselected) to display only the outcome of the job in the event. **NOTE:** You probably do not need to see every step in a data collection job unless you are debugging a problem.
Event Notification	
Raise informational event?	Select **Yes** to raise an event that provides status information. The default is Yes.
Event severity for informational event	Set the severity level, from 1 to 40, to reflect the importance of the generation of an informational event. The default is 25.
Event severity when data collection fails	Set the severity level, from 1 to 40, to reflect the importance of an event in which the data-collection attempt fails. The default is 10. **NOTE:** This parameter differs from *Event severity when job fails* in that it indicates the Data Mart has failed to collect data. It does not indicate the Knowledge Script itself has failed to run.
Event severity when data collection is cancelled	Set the severity level, from 1 to 40, to reflect the importance of an event in which the data collection job is cancelled. The default is 15.

Parameter	How to Set It
Event severity when job fails	Set the severity level, from 1 to 40, to reflect the importance of an event in which the DataCollectionStatus job fails. The default is 5. **NOTE:** This parameter differs from *Event severity when data collection fails* in that it indicates the Knowledge Script has failed to run. It does not indicate the Data Mart has failed to collect data.

17.10 ExecuteDataCollection

Use this Knowledge Script to perform on-demand data collection, regardless of the schedule. This script takes no action if data is currently being collected. Running this script does not affect the data collection schedule.

This script raises an event when the job success or fails, and when data is currently being collected.

17.10.1 Resource Objects

Call Data CallManager object

Call Data H.323 RADIUS object

Call Data CiscoCM object

17.10.2 Default Schedule

By default, this script runs once.

17.10.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Data Collection	
Start SQL Server Agent if it is stopped?	Select **Yes** to start SQL Server Agent. SQL Server Agent must be running in order for data collection tasks to be performed. The default is unselected.
Event Notification	
Event severity when job execution succeeds	Set the severity level, from 1 to 40, to reflect the importance of an event in which the ExecuteDataCollection job succeeds. The default is 25.
Event severity when job already executing	Set the severity level, from 1 to 40, to reflect the importance of a situation in which data is already being collected. The default is 25.
Event severity when job execution fails	Set the severity level, from 1 to 40, to reflect the importance of an event in which the ExecuteDataCollection job fails. The default is 5.

17.11 RemoveDataSource

Use this Knowledge Script to remove a Data Source and its associated Data Mart. This script raises an event when the removal succeeds or fails.

TIP: When this Knowledge Script job runs successfully, the Data Source object in the TreeView pane is deleted. In addition, the job itself is also deleted (a normal side-effect of removing a TreeView object). The event this job creates is not deleted because it is associated with the parent object (`CallDataAnalysis:WAREHOUSE` object). However, if you set the global preference to "Remove associated events when jobs are deleted," even the event is deleted when the object and job are deleted. To set global preferences, select **File > Preferences > Repository > Event** in the AppManager Operator Console.

17.11.1 Resource Objects

Call Data CallManager object

Call Data H.323 RADIUS object

Call Data CiscoCM object

17.11.2 Default Schedule

By default, this script runs once.

17.11.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Data Source Removal	
Check following box to confirm removal	
Confirm data source removal	Select **Yes** to confirm you want to remove the Data Source. The default is unselected. This script will not run unless you set this parameter to Yes.
Delete the data mart database?	Select **Yes** to delete the database from the Data Mart computer. The default is unselected. **NOTE:** You should not delete a database. After you delete a database, its data is lost and unavailable for use. If you do not delete the database, you can easily reconnect to it using the AddDataSource Knowledge Script.
Event Notification	
Raise event if job succeeds?	Select **Yes** to raise an event when the RemoveDataSource job succeeds. The default is Yes.
Event severity when job succeeds	Set the severity level, from 1 to 40, to reflect the importance of an event in which the RemoveDataSource job succeeds. The default is 25.
Event severity when job fails	Set the severity level, from 1 to 40, to reflect the importance of an event in which the RemoveDataSource job fails. The default is 5.

17.12 Report_CallAuthorization

Use this Knowledge Script to display the number and duration of calls that used a Forced Authorization Code (FAC) or a Client Matter Code. Both are features of Cisco Unified Communications Manager.

- An FAC is a code users must enter when attempting to make a priority phone call, such as an international call.
- A Client Matter Code is one users must enter to assign a phone call to a particular billing entity, such as a specific client or project.

This report supports only Unified Communications Manager Data Sources.

17.12.1 Identifying Unauthorized Usage

Your organization may use Forced Authorization Codes and Client Matter Codes to allow your employees to make long distance calls based on business need. However, authorization codes have a way of being shared. You can monitor authorization code usage with the Report_CallAuthorization Knowledge Script.

Let us say your billing records indicate a client account has been charged for what seems like excess telephone calls. Using Report_CallAuthorization, set the *Show calls by* parameter to **ClientMatterCode**. Set the *Show details by* parameter to **CallingLocation**. Your report will display a chart that groups calls by Client Matter Code and calling location, allowing you to easily identify which calling location is making the excess charges.

17.12.2 Resource Object

Report agent

17.12.3 Default Schedule

By default, this script runs once.

17.12.4 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Data Source	
Select data source(s)	Select the data for your report by **View Name**, **Data Warehouse**, or **Data Source**.
Select time range	Select a **Specific** or **Sliding** date/time range from which the report should pull data. The default is Sliding.
Minimum duration	Specify the minimum duration filter for calls selected by the script. Calls with a duration of less than the minimum will not be included in the report, even if all other criteria are satisfied. The default is 0 seconds.

Parameter	How to Set It
Show calls by	Select the delimiter by which you want to group the calls in your report. You can choose from the following sorting options: • **FAC Level** • **FAC Name** • **Client Matter Code**
Show details by	Select the details you want to show for each group of calls. You can choose from the following detail options: • **CallManager Cluster** • **Calling Partition** • **Called Partition** • **Calling Location** • **Called Location** • **Outbound Trunk Group** • **Inbound Trunk Group** • **Outbound Gateway** • **Inbound Gateway** • **Hour of Day** • **Day of Week** • **None**. If you select None, no time details are shown.
Report Settings	
Include parameter help card?	Set to **y** to include a table in the report that lists parameter settings for the report script. The default is y.
Include table?	Set to **y** to include a table of data stream values in the report. The default is y.
Include chart?	Set to **y** to include a chart of data stream values in the report. The default is y.
Units for chart	Select the unit of measurement that should appear on the Y axis of the chart: **Duration** or **Number Of Calls**. The default is Number of Calls. If you select Duration, the duration unit measurement is determined by the value you select in the *Show duration in Erlangs or seconds?* parameter.

Show duration in Erlangs or seconds?	Select whether you want the duration measurement to display in **Erlangs** or **Seconds**. The default is Erlangs.
	Also known as a traffic unit, an Erlang is a measurement of traffic load during the busy hour, and is based on having 3600 seconds (60 minutes or one hour) of calls on the same circuit, trunk, or port. (In other words, one circuit is busy for one hour regardless of the number of calls or the average length of calls). For example, if a call center received 30 six-minutes calls in the busy hour, it received 180 call minutes, or three Erlangs. If a call center received 100 calls that averaged 36 seconds in the busy hour, it received 3600 call seconds or one Erlang.
	You can use the following formula to calculate an Erlang value:
	`Traffic in Erlangs =`
	`(Number of calls in the busy hour) * (AHT seconds)/3600`

Include “Unassigned” in summary chart?	Set to **y** to include all calls for which no FAC or Client Matter Code was used. The default is y.

Parameter	How to Set It
Select chart style	Define the graphic properties for the charts in your report. The default style is Bar.
Select output folder	Set parameters for the output folder. The default folder name is CallAuthorization.
Add job ID to output folder name?	Set to **y** to append the job ID to the name of the output folder. The default is n. A job ID is helpful for making the correlation between a specific instance of a Report script and the corresponding report.
Select properties	Set miscellaneous report properties as desired. The default report name is Call Authorization.
Add time stamp to title?	Set to **y** to append a time stamp to the title of the report, making each title unique. The default is n. The time stamp is made up of the date and time the report was generated. Adding a time stamp is useful in order to run consecutive iterations of the same report without overwriting previous output.
Event Notification	
Raise event if report succeeds?	Set to **y** to raise an event if the report is successfully generated. The default is y.
Event severity when report succeeds	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report is successful. The default is 35.
Event severity when report has no data	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report contains no data. The default is 25.
Event severity when report fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report fails. The default is 5.

17.13 Report_CallCompletionRate

Use this Knowledge Script to determine the completion rate of calls recorded with the selected Data Source. The call completion rate takes into account failed calls (determined by the disconnect cause code) and abandoned calls (calls with a successful disconnect cause code, but having a duration of zero).

NOTE: Unlike other modules, for the Call Data Analysis module, the Report agent pulls data from the Data Warehouse rather than from the AppManager repository. The Report agent uses Windows authentication to access the Data Warehouse.

17.13.1 Resource Object

Report agent

17.13.2 Default Schedule

By default, this script runs once.

17.13.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Data Source	
Select data source(s)	Select the data for your report by **View Name**, **Data Warehouse**, or **Data Source**.
Select time range	Select a **Specific** or **Sliding** date/time range from which the report should pull data. The default is Sliding.

Parameter	How to Set It
Group by	Select the delimiter by which you want to group the calls in your report. You can choose from the following sorting options: • **Data Publisher**. Choose this option to sort the report by the entity that generates the data: Communications Manager Publisher, Communications Manager primary server, or RADIUS gateway. • **Calling Partition** (applies to Communications Manager Data Sources) • **Called Partition** (applies to Communications Manager Data Sources) • **Calling Location** (applies to Communications Manager Data Sources) • **Called Location** (applies to Communications Manager Data Sources) • **Outbound Trunk Group** (applies to Communications Manager Data Sources) • **Inbound Trunk Group** (applies to Communications Manager Data Sources) • **Outbound Gateway** (applies to all Data Sources) • **Inbound Gateway** (applies to all Data Sources) • **CallManager Cluster**. This option provides the same sorting results as Data Publisher. This option is maintained in the script to provide backwards compatibility to older versions of AppManager for Call Data Analysis. • **None**. Choose this option to combine all calls into a single group. **NOTE:** If your *Select data source(s)* and *Group by* selections are incompatible (perhaps you selected an H.323 Data Source and a Communications Manager grouping), the report ignores your *Group by* selection and uses the default selection, which is Data Publisher.
Show time details by	Select the time details you want to show for each group of calls. You can choose from the following detail options: • **Hour of Day** • **Day of Week** • **Day of Month** • **None**. If you select None, no time details are shown.
Exclude these failure codes	Type a list of termination codes (separated by commas) that are not to be considered failures. See "Termination Codes" on page 743 for a list of available codes. **NOTE:** Codes 0, 16, 31, 126, and 393216 are automatically excluded. They are normal termination codes. However, these codes may appear in events if the other side of the call has a failure code that has not been excluded.
Report Settings	
Include parameter help card?	Set to **y** to include a table in the report that lists parameter settings for the report script. The default is y.
Include table?	Set to **y** to include a table of data stream values in the report. The default is y.
Include chart?	Set to **y** to include a chart of data stream values in the report. The default is y.
Select chart style	Define the graphic properties for the charts in your report. The default style is Bar.
Select output folder	Set parameters for the output folder. The default folder name is CallDataCompletionRate.

Parameter	How to Set It
Add job ID to output folder name?	Set to **y** to append the job ID to the name of the output folder. The default is n. A job ID is helpful for making the correlation between a specific instance of a Report script and the corresponding report.
Select properties	Set miscellaneous report properties as desired. The default report name is Call Completion Rate.
Add time stamp to title?	Set to **y** to append a time stamp to the title of the report, making each title unique. The default is n. The time stamp is made up of the date and time the report was generated. Adding a time stamp is useful in order to run consecutive iterations of the same report without overwriting previous output.
Event Notification	
Raise event if report succeeds?	Set to **y** to raise an event if the report is successfully generated. The default is y.
Event severity when report succeeds	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report is successful. The default is 35.
Event severity when report has no data	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report contains no data. The default is 25.
Event severity when report fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report fails. The default is 5.

17.14 Report_CallDetail_CiscoCallMgr

Use this Knowledge Script to display details for calls that match criteria you specify for a selected Unified Communications Manager. Call details can include time, calling number, and called number. Any criteria parameter you leave blank is not included in the search.

NOTE: Unlike other modules, for the Call Data Analysis module, the Report agent pulls data from the Data Warehouse rather than from the AppManager repository. The Report agent uses Windows authentication to access the Data Warehouse.

17.14.1 Identifying Malicious Calls

This report can aid you in identifying malicious calls for a VoIP security assessment. Your company may have its own definition of what constitutes a malicious call, but in general, a malicious call is disturbing or harmful to the recipient. Examples of malicious calls include incoming fax calls, calls from telemarketers, or calls from external recruiters.

Cisco Unified Communications Manager provides a Malicious Call ID feature. When configured, this feature allows a user to identify a malicious call by pressing a soft key. Communications Manager stores information about the unwanted call in the CDR database. AppManager can filter the CDR database for any call flagged as malicious.

Using the Report_CallDetail_CiscoCallMgr Knowledge Script and the *Calls identified as malicious* parameter, you can create a report that identifies the time, number, and IP address of the malicious caller. By also specifying a **CalledNumber** or **CallingNumber** in the *Search Criteria* parameter, you can filter the report to display all malicious calls to or from a particular number.

Let us say your engineers were being plagued with calls from an outside recruiter. They identified the calls as malicious and you ran Report_CallDetails to pinpoint the calling number. After you identified the malicious calling number, you routed future calls from this number through your voice gateway to your main phone operator. Your operator quickly dispatched the recruiter and your engineers returned to their work.

What if one of your employees receives a disturbing or malicious call, but is using a phone that is not equipped to flag a malicious call? You can use the Report_CallDetails Knowledge Script and the time of the call to create a report that displays all calls within a certain time period. Use the *Select time range* parameter to indicate the time of the call. Then supply the employee's phone number in the *Search criteria - Called number* parameter. AppManager will search the CDR database for all calls to the employee's number that occurred during the period you specified.

17.14.2 Resource Object

Report agent

17.14.3 Default Schedule

By default, this script runs once.

17.14.4 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Data Source	
Select data source	Select the data for your report by **View Name**, **Data Warehouse**, or **Data Source**.
Select time range	Select a **Specific** or **Sliding** date/time range from which the report should pull data. The default is Sliding.
Minimum duration	Specify a minimum duration for calls selected by the script. Calls with a duration of less than the minimum will not be included in the report, even if all other criteria are satisfied. Type 0 to indicate no limit.
Maximum duration	Specify a maximum duration for calls selected by the script. Calls with a duration of greater than the maximum will not be included in the report, even if all other criteria are satisfied. Type 0 to indicate no limit.
Search Criteria	
Note for entering search criteria: If you specify only the wildcard (*) for a field (such as calling number), AppManager matches *only* those calls that have a value for that field. Calls for which that field has no value (i.e., is NULL) will not be matched. For example, if you specify * in the *Calling partition name* parameter, the search matches only those calls that have some partition name configured. To match all calls (including calls that have no value for the selected field), leave the search criteria parameter blank.	
Calling number	Specify the calling number you want to find.
Called number	Specify the called number you want to find.
Calling device name	Specify the name of the calling device you want to find.
Called device name	Specify the name of the called device you want to find.
Calling device IP address	Specify the IP addresses of the calling devices you want to find. Use one of the following formats: • Single dotted-decimal IP address, such as 10.41.2.31 • Dotted-decimal IP address that includes a wildcard, such as 10.41.*.*, which would search for all IP addresses in the range of 10.41.0.0 to 10.41.255.255. • Range of dotted-decimal IP addresses separated by a hyphen, such as 10.41.2.31-10.41.2.41. The first address indicates the beginning of the range; the second IP address marks the end of the range.
Called device IP address	Specify the IP addresses of the called devices you want to find. Use one of the following formats: • Single dotted-decimal IP address, such as 10.41.2.31 • Dotted-decimal IP address that includes a wildcard, such as 10.41.*.*, which would search for all IP addresses in the range of 10.41.0.0 to 10.41.255.255. • Range of dotted-decimal IP addresses separated by a hyphen, such as 10.41.2.31-10.41.2.41. The first address indicates the beginning of the range; the second IP address marks the end of the range.
Calling device location name	Specify the name of the calling device location you want to find. Use the location configured on the Communications Manager.
Called device location name	Specify the name of the called device location you want to find. Use the location configured on the Communications Manager.

Parameter	How to Set It
Calling partition name	Specify the name of the calling partition you want to find.
Called partition name	Specify the name of the called partition you want to find.
Inbound trunk group name	Specify the name of the inbound trunk group you want to find.
Outbound trunk group name	Specify the name of the outbound trunk group you want to find.
Calls identified as malicious	Select **Yes** to search for calls identified as malicious by call recipients. The default is unselected.
Forced Authorization Code (FAC) level or range of levels	Specify the FAC level you want to find. Specify a single FAC level, such as `30`, or a range of levels separated by a hyphen, such as `30-50`. The maximum level is 255. To search for all levels above a certain point, specify a range that begins with the certain point and ends with 255, such as `30-255`. **NOTE:** An FAC is a code users must enter when attempting to make a priority phone call, such as an international call.
Forced Authorization Code (FAC) name	Specify the FAC name you want to find. An FAC is a code users must enter when attempting to make a priority phone call, such as an international call. The text string can contain the * wildcard.
Client Matter Code	Specify the client matter code you want to find. A client matter code is one users must enter to assign a phone call to a particular billing entity, such as a specific client or project. The text string can contain the * wildcard.
Comment field	Specify a string of text you want to find in the CDR Comment field. The text string can contain the * wildcard.

Custom SQL filter	Specify a SQL clause to filter the results in the report.
	
	NOTE: To use this parameter properly, the SQL clause must be designed so that it could be used in a WHERE clause. However, you do not need to mention the WHERE clause in the parameter text. Below are three examples:
	
	`Duration=0 and OrigNumberPacketsSent is null`
	
	`Duration=0`
	
	`Comment like 'C%'`

Call Details to Include in Report	
Call duration	Select to include call duration in the call details for each call in the report. The default is checked.
Call type	Select to include call classification type in the call details for each call in the report. The default is unselected. For more information, see "Reviewing Call Classification Types" on page 711.
Originator disconnect cause code	Select to include the disconnect cause code in the call details for each originator call included in the report. The default is checked.
Destination disconnect cause code	Select to include the disconnect cause code in the call details for each destination call included in the report. The default is checked.
Call ID	Select to include the call ID in the call details for each call in the report. The default is unselected. The call ID is a globally unique identifier (GUID) that identifies the call. AppManager uses the call ID from the pkid field in the CallDetailRecord table in the Communications Manager CDR database.

Parameter	How to Set It
Partition and Device Information	
Calling number partition name	Select to include the name of the calling number partition in the call details for each call in the report. The default is unselected.
Calling device location name	Select to include the name of the calling device location in the call details for each call in the report. Use the location configured on the Communications Manager. The default is unselected.
Originator IP address	Select to include the IP address of the originating phone in the call details for each call in the report. The default is unselected.
Originator device name	Select to include the name of the originating device in the call details for each call in the report. The default is unselected.
Originator media IP address	Select to include the IP address of the device that originated the media for the call. • For Cisco IP calls, this selection returns the address of the Cisco IP phone. • For PSTN calls, this selection returns the address of the gateway. • For intercluster calls, this selection returns the address of the remote Cisco IP phone.
Originator media port	Select to include the IP port number associated with the originating media IP address.
Inbound trunk group name	Select to include the name of the inbound trunk group in the call details for each call in the report. The default is unselected. **NOTE:** This parameter is applicable only when a gateway is involved.
Called number partition name	Select to include the name of the called number partition in the call details for each call in the report. The default is unselected.
Called device location name	Select to include the name of the called device location in the call details for each call in the report. Use the location configured on the Communications Manager. The default is unselected.
Destination IP address	Select to include the IP address of the destination phone in the call details for each call in the report. The default is unselected.
Destination device name	Select to include the name of the destination device in the call details for each call in the report. The default is unselected.
Destination media IP address	Select to include the IP address of the device that terminated the media for the call. • For Cisco IP calls, this selection returns the address of the Cisco IP phone. • For PSTN calls, this selection returns the address of the H.323 gateway. • For intercluster calls, this selection returns the address of the remote Cisco IP phone.
Destination media port	Select to include the IP port number associated with the destination media IP address.
Outbound trunk group name	Select to include the name of the outbound trunk group in the call details for each call in the report. The default is unselected. **NOTE:** This parameter is applicable only when a gateway is involved.
Quality Metrics	

Parameter	How to Set It
Originator ...	Select to include one or more originating phone metrics in the call details for each call in the report. The default is unselected. • **Codec type** • **Jitter** • **Latency**
Destination ...	Select to include the following destination phone metrics in the call details for each call in the report. The default is unselected. • **Codec type** • **Jitter** • **Latency**
Listening MOS	
Originator ...	Select to include one or more MOS-related (Mean Opinion Score) originating phone metrics in the call details for each call in the report. The default is unselected. • **Average MOS** • **Minimum MOS** • **Maximum MOS** • **Last MOS**
Destination ...	Select to include one or more MOS-related (Mean Opinion Score) destination phone metrics in the call details for each call in the report. The default is unselected. • **Average MOS** • **Minimum MOS** • **Maximum MOS** • **Last MOS**
Packets	
Originator ...	Select to include one or more packet-related originating phone metrics in the call details for each call in the report. The default is unselected. • **Packets sent** • **Packets received** • **Packets lost**
Destination ...	Select to include one or more packet-related destination phone metrics in the call details for each call in the report. The default is unselected. • **Packets sent** • **Packets received** • **Packets lost**
Concealment	

Parameter	How to Set It
Originator ...	Select to include one or more concealment-related originating phone metrics in the call details for each call in the report. Concealment metrics measure packet (frame) loss and its effect on voice quality in an impaired network. The default is unselected. • **Cumulative conceal ratio**, the cumulative ratio of concealment time over speech time observed after starting a call. • **Interval conceal ratio**, an interval-based average concealment rate, is the ratio of concealment time over speech time for the last three seconds of active speech. • **Maximum conceal ratio**, the maximum concealment ratio observed during a call. • **Conceal seconds**, the amount of time during which some concealment is observed during a call. • **Severely conceal seconds**, the amount of time during which a significant amount of concealment is observed. If the concealment observed is usually greater than 50 milliseconds or approximately 5%, the speech is probably not very audible.
Destination ...	Select to include one or more concealment-related destination phone metrics in the call details for each call in the report. Concealment metrics measure packet (frame) loss and its effect on voice quality in an impaired network. The default is unselected. • **Cumulative conceal ratio**, the cumulative ratio of concealment time over speech time observed after starting a call. • **Interval conceal ratio**, an interval-based average concealment rate, is the ratio of concealment time over speech time for the last three seconds of active speech. • **Maximum conceal ratio**, the maximum concealment ratio observed during a call. • **Conceal seconds**, the amount of time during which some concealment is observed during a call. • **Severely conceal seconds**, the amount of time during which a significant amount of concealment is observed. If the concealment observed is usually greater than 50 milliseconds or approximately 5%, the speech is probably not very audible.
Security Information	
Forced Authorization Code (FAC) level	Select to include the FAC level in the call details for each call in the report. The default is unselected.
Forced Authorization Code (FAC) name	Select to include the FAC name in the call details for each call in the report. The default is unselected.
Client Matter Code	Select to include the client matter code in the call details for each call in the report. The default is unselected.
Comment field	Select to include the contents of the CDR Comment field in the call details for each call in the report. The default is unselected.
Report Settings	

Parameter	How to Set It
Maximum number of calls to return	Specify the maximum number of calls to include in the report. The default is 1000 calls. **NOTE:** No matter how many calls you choose to include in the call details section of the report, the report will also include a small table that indicates how many calls actually met your search criteria. This number may, and probably will, exceed the number of calls you choose to return.
Order rows by?	Select one of the following call detail options as the criterion for sorting the rows in the report: • **Ascending Time** (oldest to most recent) • **Descending Time** (most recent to oldest) • **Longest Duration** (longest to shortest) • **Shortest Duration** (shortest to longest) • **Calling Number** • **Called Number** • **Calling Partition**. If you select this option, you must also check the *Calling number partition name* parameter under the Partition and device information section of this script. • **Called Partition**. If you select this option, you must also check the *Called number partition name* parameter under the Partition and Device Information section of this script. • **Calling Location**. If you select this option, you must also check the *Calling device location name* parameter under the Partition and Device Information section of this script. • **Called Location**. If you select this option, you must also check the *Called device location name* parameter under the Partition and Device Information section of this script. • **Ascending FAC Level** (lowest to highest number) • **Descending FAC Level** (highest to lowest number) • **FAC Name** • **Client Matter Code**
Include parameter help card?	Set to **y** to include a table in the report that lists parameter settings for the report script. The default is y.
Select output folder	Set parameters for the output folder. The default folder name is CallDataDetails.
Add job ID to output folder name?	Set to **y** to append the job ID to the name of the output folder. The default is n. A job ID is helpful for making the correlation between a specific instance of a Report script and the corresponding report.
Select properties	Set miscellaneous report properties as desired. The default report name is Call Details.
Add time stamp to title?	Set to **y** to append a time stamp to the title of the report, making each title unique. The default is n. The time stamp is made up of the date and time the report was generated. Adding a time stamp is useful in order to run consecutive iterations of the same report without overwriting previous output.
Event Notification	

Parameter	How to Set It
Raise event if report succeeds?	Set to **y** to raise an event if the report is successfully generated. The default is y.
Event severity when report succeeds	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report is successful. The default is 35.
Event severity when report has no data	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report contains no data. The default is 25.
Event severity when report fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report fails. The default is 5.

17.15 Report_CallDetail_H323Gateway

Use this Knowledge Script to display details for calls that match criteria you specify for a selected H.323 gateway. Call details can include time, calling number, and called number. Any criteria parameter you leave blank is not included in the search.

If you have Cisco Communications Manager Express gateways, run CCME_GetConfig to ensure the Data Collection process has access to configuration information when processing call detail records. Without the configuration information, the Data Collection process cannot determine the IP address of the Communications Manager Express phone and you will not be able to use the *Originating IP Address* and *Terminating IP Address* selection parameters in this Report script.

NOTE: Unlike other modules, for the Call Data Analysis module, the Report agent pulls data from the Data Warehouse rather than from the AppManager repository. The Report agent uses Windows authentication to access the Data Warehouse.

17.15.1 Resource Object

Report agent

17.15.2 Default Schedule

By default, this script runs once.

17.15.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Data Source	
Select data source	Select the data for your report by **View Name**, **Data Warehouse**, or **Data Source**.
Select time range	Select a **Specific** or **Sliding** date/time range from which the report should pull data. The default is Sliding.
Minimum duration	Specify a minimum duration for calls selected by the script. Calls with a duration of less than the minimum will not be included in the report, even if all other criteria are satisfied. Type 0 to indicate no limit.
Maximum duration	Specify a maximum duration for calls selected by the script. Calls with a duration of greater than the maximum will not be included in the report, even if all other criteria are satisfied. Type 0 to indicate no limit.
Search Criteria	

Parameter	How to Set It
Note for entering search criteria: If you specify only the wildcard (*) for a field (such as calling number), AppManager matches *only* those calls that have a value for that field. Calls for which that field has no value (i.e., is NULL) will not be matched. For example, if you specify * in the *Calling partition name* parameter, the search matches only those calls that have some partition name configured. To match all calls (including calls that have no value for the selected field), leave the search criteria parameter blank.	
Calling number	Specify the calling number you want to find.
Called number	Specify the called number you want to find.
Originating gateway name	Specify the name of the originating gateway you want to find.
Terminating gateway name	Specify the name of the terminating gateway you want to find.
Originating IP address	Specify the IP addresses of the originating gateways you want to find. Use one of the following formats: • Single dotted-decimal IP address, such as 10.41.2.31 • Dotted-decimal IP address that includes a wildcard, such as 10.41.*.*, which would search for all IP addresses in the range of 10.41.0.0 to 10.41.255.255. • Range of dotted-decimal IP addresses separated by a hyphen, such as 10.41.2.31-10.41.2.41. The first address indicates the beginning of the range; the second IP address marks the end of the range. For calls through the gateway from the PSTN, this search criterion returns the actual IP address of the gateway. For calls through the gateway from Communications Manager Express phones, this search criterion returns the IP address of the Communications Manager Express phones. If this IP address cannot be determined from Communications Manager Express configuration information, this search criterion returns no information.
Terminating IP address	Specify the IP addresses of the terminating gateways you want to find. You can use one of the following formats: • Single dotted-decimal IP address, such as 10.41.2.31 • Dotted-decimal IP address that includes a wildcard, such as 10.41.*.*, which would search for all IP addresses in the range of 10.41.0.0 to 10.41.255.255. • Range of dotted-decimal IP addresses separated by a hyphen, such as 10.41.2.31-10.41.2.41. The first address indicates the beginning of the range; the second IP address marks the end of the range. For calls through the gateway to the PSTN, this search criterion returns the actual IP address of the gateway. For calls through the gateway to Communications Manager Express phones, this search criterion returns the IP address of the Communications Manager Express phones. If this IP address cannot be determined from Communications Manager Express configuration information, this search criterion returns no information.
Inbound trunk group name	Specify the name of the inbound trunk group you want to find.
Outbound trunk group name	Specify the name of the outbound trunk group you want to find.
Call Details to Include in Report	
Call duration	Select to include call duration in the call details for each call in the report. The default is checked.
Call type	Select to include call classification type in the call details for each call in the report. The default is unselected. For more information, see "Reviewing Call Classification Types" on page 711.

Parameter	How to Set It
Originating gateway disconnect cause code	Select to include the disconnect cause code in the call details for each originating gateway call included in the report. The default is checked.
Terminating gateway disconnect cause code	Select to include the disconnect cause code in the call details for each terminating gateway call included in the report. The default is checked.
Call ID	Select to include the call ID in the call details for each call in the report. The default is unselected. The call ID is a globally unique identifier (GUID) that identifies the call. AppManager uses the call ID from the h323-conf-id field received in the RADIUS records; all H.323 call legs belonging to the same call will have the same h323-conf-id.
Gateway, Port, and IP Information	
Originating gateway name	Select to include the name of the originating gateway in the call details for each call in the report. The default is unselected.
Originating gateway voice port	Select to include the port number of the originating gateway voice port in the call details for each call in the report. The default is unselected.
Originating IP address	Select to include the IP address of the originating gateway or Communications Manager Express phone in the call details for each call in the report. The default is unselected.
Inbound trunk group name	Select to include the name of the inbound trunk group in the call details for each call in the report. The default is unselected.
Terminating gateway name	Select to include the name of the terminating gateway in the call details for each call in the report. The default is unselected.
Terminating gateway voice port	Select to include the port number of the terminating gateway voice port in the call details for each call in the report. The default is unselected.
Terminating IP address	Select to include the IP address of the terminating gateway or Communications Manager Express phone in the call details for each call in the report. The default is unselected.
Outbound trunk group name	Select to include the name of the outbound trunk group in the call details for each call in the report. The default is unselected.
Quality Metrics	
Originating gateway ...	Select to include the following originating gateway metrics in the call details for each call in the report. The default is unselected. • **Codec type** • **MOS** • **R-value** • **ICPIF Voice Quality** • **Packets sent** • **Packets received** • **Packets lost** • **Packets early** • **Packets late** • **Delay**

Parameter	How to Set It
Terminating gateway ...	Select to include the following terminating gateway metrics in the call details for each call in the report. The default is unselected. • **Codec type** • **MOS** • **R-value** • **ICPIF Voice Quality** • **Packets sent** • **Packets received** • **Packets lost** • **Packets early** • **Packets late** • **Delay**
Remote Session Protocol and IP Addresses	
Originating gateway session protocol	Select to include the protocol being used on the originating VoIP legs of a call. Cisco voice gateways set this information to “cisco” for the H.323 protocol.
Originating gateway remote gateway IP address	Select to include the IP address of the originating gateway’s terminating gateway in the call details for each call in the report. The default is unselected. For a call coming in through the voice gateway to an IP phone registered to a Communications Manager, the remote gateway IP address is that of the Communications Manager.
Originating gateway remote gateway port	Select to include the port number of the originating gateway’s terminating gateway in the call details for each call in the report. The default is unselected. For a call coming in through the voice gateway to an IP phone registered to a Communications Manager, the remote gateway port is that of the Communications Manager.
Originating gateway remote media IP address	Select to include the IP address of the originating gateway’s remote media in the call details for each call in the report. The default is unselected. The remote media address is the IP address to which media is streamed. For a call coming in through the voice gateway to an IP phone registered to a Communications Manager, the remote media IP address is that of the phone.
Originating gateway remote media port	Select to include the port number of the originating gateway’s terminating media in the call details for each call in the report. The default is unselected. For a call coming in through the voice gateway to an IP phone registered to a Communications Manager, the remote gateway port is that of the phone.
Terminating gateway session protocol	Select to include the protocol being used on the terminating VoIP legs of a call. Cisco voice gateways set this information to “cisco” for the H.323 protocol.

Parameter	How to Set It
Terminating gateway remote gateway IP address	Select to include the IP address of the terminating gateway's originating gateway in the call details for each call in the report. The default is unselected. For a call leaving the voice gateway from an IP phone registered to a Communications Manager, the originating gateway IP address is that of the Communications Manager.
Terminating gateway remote gateway port	Select to include the port number of the terminating gateway's originating gateway in the call details for each call in the report. The default is unselected. For a call leaving the voice gateway from an IP phone registered to a Communications Manager, the originating gateway port is that of the Communications Manager.
Terminating gateway remote media IP address	Select to include the IP address of the terminating gateway's remote media in the call details for each call in the report. The default is unselected. The remote media address is the IP address to which media is streamed. For a leaving the voice gateway from an IP phone registered to a Communications Manager, the remote media IP address is that of the phone.
Terminating gateway remote media port	Select to include the port number of the terminating gateway's originating media port in the call details for each call in the report. The default is unselected. For a call leaving the voice gateway from an IP phone registered to a Communications Manager, the remote media port is that of the phone.
Report Settings	
Maximum number of calls to return	Specify the maximum number of calls to include in the report. The default is 1000 calls. **NOTE:** No matter how many calls you choose to include in the call details section of the report, the report will also include a small table that indicates how many calls actually met your search criteria. This number may, and probably will, exceed the number of calls you choose to return.

Parameter	How to Set It
Order rows by?	Select one of the following call detail options as the criterion for sorting the rows in the report: • Ascending Time (oldest to most recent) • Descending Time (most recent to oldest) • Longest Duration (longest to shortest) • Shortest Duration (shortest to longest) • Calling Number • Called Number • Orig Gateway Name. If you select this option, also check the Originating gateway name parameter under the Gateway and Port information folder of this script. • Term Gateway Name. If you select this option, also check the Terminating gateway name parameter under the Gateway and Port Information folder of this script. • Inbound Trunk Group. If you select this option, also check the Inbound trunk group name parameter under the Gateway and Port information folder of this script. • Outbound Trunk Group. If you select this option, also check the Outbound trunk group name parameter under the Gateway and Port information folder of this script.
Include parameter help card?	Set to **y** to include a table in the report that lists parameter settings for the report script. The default is y.
Select output folder	Set parameters for the output folder. The default folder name is CallDetail_H323Gateway.
Add job ID to output folder name?	Set to **y** to append the job ID to the name of the output folder. The default is n. A job ID is helpful for making the correlation between a specific instance of a Report script and the corresponding report.
Select properties	Set miscellaneous report properties as desired. The default report name is Cisco H.323 Gateway Call Details.
Add time stamp to title?	Set to **y** to append a time stamp to the title of the report, making each title unique. The default is n. The time stamp is made up of the date and time the report was generated. Adding a time stamp is useful in order to run consecutive iterations of the same report without overwriting previous output.
Event Notification	
Raise event if report succeeds?	Set to **y** to raise an event if the report is successfully generated. The default is y.
Event severity when report succeeds	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report is successfully generated. The default is 35.
Event severity when report has no data	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report contains no data. The default is 25.
Event severity when report fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report cannot be generated. The default is 5.

17.16 Report_CallFailureCauses

Use this Knowledge Script to analyze the failure causes for calls matching criteria you specify. You can select more than one filter in the Search Criteria parameters.

NOTE: Unlike other modules, for the Call Data Analysis module, the Report agent pulls data from the Data Warehouse rather than from the AppManager repository. The Report agent uses Windows authentication to access the Data Warehouse.

Resource Object

Report agent

Default Schedule

By default, this script runs once.

Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Data Source	
Select data source	Select the data for your report by **View Name**, **Data Warehouse**, or **Data Source**.
Select time range	Select a **Specific** or **Sliding** date/time range from which the report should pull data. The default is Sliding.
Exclude these failure codes	Specify a list of termination codes (separated by commas) that are not to be considered failures. See Termination Codes for a list of available codes. **NOTE:** Codes 0, 16, 31, 126, and 393216 are automatically excluded. They are normal termination codes. However, these codes may appear in events if the other side of the call has a failure code that has not been excluded.
Minimum duration	Specify the minimum duration filter for calls selected by the script. Calls with a duration of less than the minimum will not be included in the report, even if all other criteria are satisfied. The default is 0 seconds.
Search Criteria	
Note for entering search criteria: If you specify only the wildcard (*) for a field (such as calling number), AppManager matches *only* those calls that have a value for that field. Calls for which that field has no value (i.e., is NULL) will not be matched. For example, if you specify * in the *Calling partition name* parameter, the search matches only those calls that have some partition name configured. To match all calls (including calls that have no value for the selected field), leave the search criteria parameter blank.	
Calling number	Specify the calling number you want to find.
Called number	Specify the called number you want to find.
Calling device name	Specify the name of the calling device you want to find.

Parameter	How to Set It
Called device name	Specify the name of the called device you want to find.
Calling device IP address	Specify the IP addresses of the calling devices you want to find. Use one of the following formats: • Single dotted-decimal IP address, such as 10.41.2.31 • Dotted-decimal IP address that includes a wildcard, such as 10.41.*.*, which would search for all IP addresses in the range of 10.41.0.0 to 10.41.255.255. • Range of dotted-decimal IP addresses separated by a hyphen, such as 10.41.2.31-10.41.2.41. The first address indicates the beginning of the range; the second IP address marks the end of the range.
Called device IP address	Specify the IP addresses of the called devices you want to find. Use one of the following formats: • Single dotted-decimal IP address, such as 10.41.2.31 • Dotted-decimal IP address that includes a wildcard, such as 10.41.*.*, which would search for all IP addresses in the range of 10.41.0.0 to 10.41.255.255. • Range of dotted-decimal IP addresses separated by a hyphen, such as 10.41.2.31-10.41.2.41. The first address indicates the beginning of the range; the second IP address marks the end of the range.
Calling device location name	Specify the name of the calling device location you want to find. Use the location configured on the Communications Manager.
Called device location name	Specify the name of the called device location you want to find. Use the location configured on the Communications Manager.
Calling partition name	Specify the name of the calling partition you want to find.
Called partition name	Specify the name of the called partition you want to find.
Inbound trunk group name	Specify the name of the inbound trunk group you want to find.
Outbound trunk group name	Specify the name of the outbound trunk group you want to find.
Report Settings	
Include parameter help card?	Set to **y** to include a table in the report that lists parameter settings for the report script. The default is y.
Include table?	Set to **y** to include a table of data stream values in the report. The default is y.
Include time details table?	Set to **y** to include the time details table in the report. The time details table presents a breakdown of the failure causes that occurred during each hour of the reporting period.
Include chart?	Set to **y** to include a chart of data stream values in the report. The default is y.
Select chart style	Define the graphic properties for the charts in your report. The default style is Pie.
Select output folder	Set parameters for the output folder. The default folder name is CallDataFailureCauses.
Add job ID to output folder name?	Set to **y** to append the job ID to the name of the output folder. The default is n. A job ID is helpful for making the correlation between a specific instance of a Report script and the corresponding report.

Parameter	How to Set It
Select properties	Set miscellaneous report properties as desired. The default report name is Call Failure Causes.
Add time stamp to title?	Set to **y** to append a time stamp to the title of the report, making each title unique. The default is n. The time stamp is made up of the date and time the report was generated. Adding a time stamp is useful in order to run consecutive iterations of the same report without overwriting previous output.
Event Notification	
Raise event if report succeeds?	Set to **y** to raise an event if the report is successfully generated. The default is y.
Event severity when report succeeds	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report is successful. The default is 35.
Event severity when report has no data	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report contains no data. The default is 25.
Event severity when report fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report fails. The default is 5.

17.16.1 Termination Codes

Use this list of termination codes (also known as call release cause codes) to complete the *Exclude these failure codes* parameter.

Termination Code	Description	Explanation
0	No error	No error.
1	Unallocated (unassigned) number	Indicates the called party cannot be reached because, although the called party number is in a valid format, it is not currently allocated (assigned).
2	No route to specified transit network (national use)	Indicates one of the following: • The equipment sending this code has received a request to route the call through a transit network it does not recognize. The equipment does not recognize the transit network either because the transit network does not exist or because the transit network exists but does not serve the equipment sending the code. • The prefix 0 is invalid for the entered number.
3	No route to destination	Indicates one of the following: • The called party cannot be reached because the network through which the call has been routed does not service the desired destination. This cause is supported on a network-dependent basis. • A 1 was dialed when not required. Redial without the 1.

Termination Code	Description	Explanation
4	Send special information tone	Indicates one of the following: • The prefix 1 is not required for this number. • The called party cannot be reached for reasons of a long-term nature. The special information tone should be returned to the calling party.
5	Misdialed trunk prefix (national use)	Indicates the erroneous inclusion of a trunk prefix in the called party number.
6	Channel unacceptable	Indicates a called user cannot negotiate for a B-channel other than that specified in the SETUP message.
7	Call awarded and being delivered in an established channel	Indicates the user has been awarded the incoming call and the call is being connected to a channel (such as packet mode or X.25 virtual calls) already established to that user for similar calls.
8	Preemption	Indicates a call has been preempted.
9	Preemption - circuit reserved for reuse	Indicates a call has been preempted because the circuit is reserved for reuse.
16	Normal call clearing	Indicates normal call clearing has occurred.
17	User busy	Indicates the called party is unable to accept another call because the user busy condition has been encountered. Code 17 may be generated by the called user or by the network. In the case of user-determined user busy, it is noted that the user equipment is compatible with the call.
18	No user responding	Indicates a called party does not respond to a call establishment message with an alerting or connect indication within the allotted prescribed period of time (before timer T303 or T310 has expired).
19	No answer from user (user alerted)	Indicates the called user has provided an alerting indication, but not a connect indication within a prescribed period of time (before timer T301 has expired).
20	Subscriber absent	Indicates one of the following: • A mobile station has logged off. • Radio contact is not obtained with a mobile station. • A personal telecommunications user is temporarily not addressable at any user-network interface.
21	Call rejected	Indicates one of the following: • The equipment sending this cause does not want to accept the call, although it could have accepted the call because it is neither busy nor incompatible. • May be generated by the network, indicating the call was cleared due to a supplementary service constraint.
22	Number changed	Indicates the called party number indicated by the calling party is no longer assigned. The new called party number may optionally be included in the diagnostic field. If a network does not support this cause, cause #1 shall be used.
26	Non-selected user clearing	Indicates the user has not been awarded the incoming call.

Termination Code	Description	Explanation
27	Destination out of order	Indicates the destination indicated by the user cannot be reached because the interface to the destination is not functioning correctly. The term "not functioning correctly" indicates a signal message was unable to be delivered to the remote party, as in the following examples: • Physical layer or data link layer failure at the remote party • User equipment off-line
28	Invalid number format (address incomplete)	Indicates one of the following: • The called party cannot be reached because the called party number is not in a valid format or is not complete. • The user should be returned a Special Intercept Announcement.
29	Facility rejected	Indicates one of the following: • The network cannot provide the requested facility. • A user in a special business group, such as a Centrex, dialed an undefined code.
30	Response to STATUS ENQUIRY	Indicates one of the following: • This cause is included in the Status Message when the reason for sending the Status Message was the previous receipt of a Status Enquiry message. • A user from outside a basic business group, such as a Centrex, has violated an access restriction feature.
31	Normal, unspecified	Used to report a normal event only when no other cause in the normal class applies.
34	No circuit/channel available	Indicates no appropriate circuit or channel is available to handle the call.
38	Network out of order	Indicates the network is not functioning correctly and the condition is likely to last a relatively long time. Immediately re-attempting the call is not likely to be successful.
39	Permanent frame mode connection out of service	Indicates a permanent connection was terminated, probably due to equipment failure.
40	Permanent frame mode connection operational	Indicates a permanent connection is operational again. The connection was previously terminated, probably due to equipment failure.
41	Temporary failure	Indicates the network is not functioning correctly and the condition is not likely to last a long time. The user may want to attempt another call almost immediately. May also indicate a data link layer malfunction locally or at the remote network interface, or a call was cleared due to protocol error(s) at the remote network interface.
42	Switching equipment congestion	Indicates the switching equipment generating this cause is experiencing a period of high traffic.
43	Access information discarded	Indicates the network is unable to deliver user information (such as user-to-user information, low-level compatibility, or sub-address) to the remote users as requested.

Termination Code	Description	Explanation
44	Requested circuit/channel not available	Indicates the other side of the interface cannot provide the circuit or channel indicated by the requesting entity.
46	Precedence call blocked	Indicates the remote device that was called is busy.
47	Resource unavailable, unspecified	Indicates one of the following: • No other cause in the resource unavailable class applies. • The original destination is unavailable. Invoke redirection to a new destination.
49	Quality of Service not available	Indicates the network cannot provide the requested Quality of Service. May be a subscription problem.
50	Requested facility not subscribed	Indicates this facility is unavailable because the user has not subscribed to it.
53	Service operation violated	Indicates the user has violated the service operation.
54	Incoming calls barred	Indicates the user will not accept the call delivered in the SETUP message.
55	Incoming calls barred within Closed User Group (CUG)	Indicates the network does not allow the user to receive calls.
57	Bearer capability not authorized	Indicates the user has requested a bearer capability implemented by the equipment that generated this cause. However, the user is not authorized to use it. This common problem is caused by incorrect Telco provisioning of the line at the time of installation.
58	Bearer capability not presently available	Indicates the user has requested a bearer capability implemented by the equipment that generated this cause. However, bearer capability is unavailable at the present time. This problem may be due to a temporary network problem or a subscription problem.
62	Inconsistency in designated outgoing access information and subscriber class	Indicates an inconsistency in the designated outgoing access information and subscriber class.
63	Service or option not available, unspecified	Indicates a service or option is not available. Used only when no other cause in this class applies.
65	Bearer capability not implemented	Indicates the equipment sending this cause does not support the requested bearer capability.
66	Channel type not implemented	Indicates the called party has reached an unsupported channel type.
69	Requested facility not implemented	Indicates the network (or node) does not support the requested bearer capability and therefore cannot be accessed at this time.
70	Only restricted digital information bearer capability available (national use)	Indicates the calling party has requested an unrestricted bearer service. However, the equipment sending this cause supports only the restricted version of the requested bearer capability.
79	Service or option not implemented, unspecified	Indicates a service or option was not implemented. Used only when no other cause in this class applies.

Termination Code	Description	Explanation
81	Invalid call reference value	Indicates the equipment sending this cause has received a message with a call reference not currently in use on the user-network interface. This value applies only if the call reference value is 1 or 2 octets long and is not the global call reference.
82	Identified channel does not exist	Indicates the equipment sending this cause has received a request to use a channel not active on the interface for a call.
83	A suspended call exists, but this call identity does not	Indicates a suspended call exists but the call's identity does not.
84	Call identity in use	Indicates a call identity is in use.
85	No call suspended.	Indicates no call is suspended.
86	Call having the requested call identity has been cleared	Indicates the call having the requested call identity has cleared.
87	User not member of Closed User Group (CUG)	Indicates the call was not completed, probably due to one of the following reasons: • The dialed number is incorrect • The user is not authorized to use (or has not subscribed to) the requested service • User is using a service the remote device is not authorized to use
88	Incompatible destination	Indicates the equipment sending this cause has received a request to establish a call that has low layer compatibility, high layer compatibility, or other compatibility attributes (such as data rate or DN subaddress), which cannot be accommodated. This call can be returned by a switch to a CPE when trying to route a call to an incompatible facility, or one without a data rate.
90	Destination number missing and DC not subscribed	Indicates the call was not completed, probably due to one of the following reasons: • The dialed number is incorrect • The user is not authorized to use (or has not subscribed to) the requested service • User is using a service the remote device is not authorized to use
91	Invalid transit network selection (national use)	Indicates an invalid transit network selection has been requested.
95	Invalid message, unspecified	Indicates the entity sending this cause has received an invalid message. Used when no other cause in this class applies.
96	Mandatory information element is missing	Indicates the equipment sending this cause has received a message that is missing an information element that must be present in the message before the message can be processed.

Termination Code	Description	Explanation
97	Message type non-existent or not implemented	Indicates one of the following: • The equipment sending this cause has received a message type it does not recognize. Either the message is not defined, or it is defined and not implemented by the equipment sending this cause. • A problem with the remote configuration or with the local D-channel.
98	Message not compatible with the call state, or the message type is non-existent or not implemented	Indicates one of the following: • Message received is not compatible with the call state • Message type is non-existent or not implemented
99	An information element or parameter non-existent or not implemented	Indicates the equipment sending this cause has received a message that includes information elements not recognized because either the information element identifier is not defined, or it is defined but not implemented by the equipment sending the cause. However, the information element is not required for the equipment sending the cause to process the message.
100	Invalid information element contents	Indicates the equipment sending this cause has received an information element it has implemented. However, one or more fields of the information elements are coded in such a way (such as truncated, invalid extension bit, invalid field values) that the information element has not been implemented by the equipment sending this cause.
101	The message not compatible with the call state	Indicates one of the following: • The equipment sending this cause has received a message that procedures indicate is not a permissible message to receive at this time. • The switch sending this cause is clearing the call because a threshold has been exceeded for multiple protocol errors during an active call.
102	Call terminated when timer expired; a recovery routine executed to recover from the error	Indicates a procedure has been initiated by the expiration of a timer in associated with error-handling procedures.
103	Parameter non-existent or not implemented - passed on (national use)	Indicates the equipment sending this cause has received a message that includes parameters not recognized because the parameters are defined but not implemented by the equipment sending the cause. The parameters were ignored. In addition, if the equipment sending this cause is an intermediate point, this cause indicates the parameters were passed on unchanged.
110	Message with unrecognized parameter discarded	Indicates the equipment sending this cause has discarded a received message that includes a parameter that is not recognized.
111	Protocol error, unspecified	Reports a protocol error event only when no other cause in this class applies. This cause may be displayed if the user failed to dial a 9 or an 8 for an outside line. In addition, this cause may be returned in the event of certain types of restrictions as to number of calls.

Termination Code	Description	Explanation
122	Precedence level exceeded	Indicates users attempted to make a call with a higher level of precedence than the highest precedence level authorized for their line.
123	Device not preemptable	Indicates one of the following: • The dialed number is non-preemptable. That is, the dialed number registers as busy and has no call waiting, no call forwarding, and no alternate party designations. • The dialed number has a higher precedence level (or priority) than the dialing number and cannot be preempted.
125	Out of bandwidth	Indicates not enough bandwidth was found to connect a call to the destination location.
126	Call split	A Cisco-specific code used by Communications Manager. Indicates a call was terminated during a transfer operation because it was split off and terminated (not part of the final transferred call). This code can help determine which calls were terminated as part of a feature operation.
127	Interworking, unspecified	Indicates an interworking call (usually a call to SW56 service) has ended. May also be seen in the event of a non-specific rejection by a long distance carrier.
129	Precedence out of bandwidth	Indicates not enough bandwidth was found to connect a precedence call to the destination location.
262144 0x40000	Conference full	A Cisco-specific code. Indicates a conference is at full capacity and can accept no new callers.
393216 0x60000	Call split	A Cisco-specific code used by Unified Communications Manager. Indicates a call was terminated during a transfer operation because it was split off and terminated (not part of the final transferred call). This code can help determine which calls were terminated as part of a feature operation.
458752 0x70000	Drop any party/drop last party	A Cisco-specific code. Indicates a call was dropped from a conference by the new feature "drop any party/drop last party."

17.17 Report_CallJitter

Use this Knowledge Script to categorize calls as having good, acceptable, or poor jitter based on thresholds you set. Calls that do not have a jitter measurement are categorized as having "no data."

You can select only Unified Communications Manager Data Sources for this report. H.323 gateways do not provide jitter measurements.

NOTE: Unlike other modules, for the Call Data Analysis module, the Report agent pulls data from the Data Warehouse rather than from the AppManager repository. The Report agent uses Windows authentication to access the Data Warehouse.

17.17.1 Resource Object

Report agent

17.17.2 Default Schedule

By default, this script runs once.

17.17.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Data Source	
Select data source(s)	Select the data for your report by **View Name**, **Data Warehouse**, or **Data Source**.
Select time range	Select a **Specific** or **Sliding** date/time range from which the report should pull data. The default is Sliding.
Minimum duration	Specify the minimum duration filter for calls selected by the script. Calls with a duration of less than the minimum will not be included in the report, even if all other criteria are satisfied. The default is 1 second. **NOTE:** Calls that are not completed (i.e., have a duration of 0 seconds) do not generate call jitter data. Therefore, the minimum duration default is 1 second.

Parameter	How to Set It
Group by	Select the delimiter by which you want to group the calls in your report. You can choose from the following sorting options: • **Data Publisher**. Choose this option to sort the report by the Communications Manager Publisher or the Unified Communications Manager primary server. • **Calling Partition** • **Called Partition** • **Calling Location** • **Called Location** • **Outbound Trunk Group** • **Inbound Trunk Group** • **Outbound Gateway** • **Inbound Gateway** • **CallManager Cluster**. This option provides the same sorting results as Data Publisher. This option is maintained in the script to provide backwards compatibility to older versions of AppManager for Call Data Analysis. • **None**. Choose this option to combine all calls into a single group.
Show time details by	Select the time details you want to show for each group of calls. You can choose from the following detail options: • **Hour of Day** • **Day of Week** • **Day of Month** • **None**. If you select None, no time details are shown.
Thresholds	
Threshold - Good-Acceptable jitter	Specify the value below which the call is acceptable and equal to or above which the call is good. The default is 40 ms.
Threshold - Acceptable-Poor jitter	Specify the value below which the call is poor and above which the call is acceptable. The default is 60 ms.
Report Settings	
Include parameter help card?	Set to **y** to include a table in the report that lists parameter settings for the report script. The default is y.
Include table?	Set to **y** to include a table of data stream values in the report. The default is y.
Include chart?	Set to **y** to include a chart of data stream values in the report. The default is y.
Select chart style	Define the graphic properties for the charts in your report. The default style is Bar_Stacked. **NOTE:** To create a chart that indicates the percentage for each category, select **Pie**.
Select output folder	Set parameters for the output folder. The default folder name is CallDataJitter.

Parameter	How to Set It
Add job ID to output folder name?	Set to **y** to append the job ID to the name of the output folder. The default is n. A job ID is helpful for making the correlation between a specific instance of a Report script and the corresponding report.
Select properties	Set miscellaneous report properties as desired. The default report name is Call Jitter.
Add time stamp to title?	Set to **y** to append a time stamp to the title of the report, making each title unique. The default is n. The time stamp is made up of the date and time the report was generated. Adding a time stamp is useful in order to run consecutive iterations of the same report without overwriting previous output.
Event Notification	
Raise event if report succeeds?	Set to **y** to raise an event if the report is successfully generated. The default is y.
Event severity when report succeeds	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report is successful. The default is 35.
Event severity when report has no data	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report contains no data. The default is 25.
Event severity when report fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report fails. The default is 5.

17.18 Report_CallJitterLoss

Use this Knowledge Script to categorize the percentage of calls lost due to jitter as being good, acceptable, or poor based on thresholds you set. Only calls from H.323 RADIUS Data Sources can be included in this report because only these Data Sources provide information about discarded packets.

Jitter loss calculations are based on the number of packets received and the number of packets discarded. Discarded packets are those that arrive too early or too late to be stored in the jitter buffer.

Calls that contain no information about received and discarded packets are placed into a "no data" category. In addition, calls that are not completed are not included in the report; they do not contain information about received and discarded packets.

NOTE: Unlike other modules, for the Call Data Analysis module, the Report agent pulls data from the Data Warehouse rather than from the AppManager repository. The Report agent uses Windows authentication to access the Data Warehouse.

17.18.1 Resource Object

Report agent

17.18.2 Default Schedule

By default, this script runs once.

17.18.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Data Source	
Select data source(s)	Select the data for your report by **View Name**, **Data Warehouse**, or **Data Source**.
Select time range	Select a **Specific** or **Sliding** date/time range from which the report should pull data. The default is Sliding.
Minimum duration	Specify the minimum duration filter for calls selected by the script. Calls with a duration of less than the minimum will not be included in the report, even if all other criteria are satisfied. The default is 1 second. **NOTE:** Calls that are not completed (i.e., have a duration of zero seconds) do not generate data about received and discarded packets. Therefore, the minimum duration default is 1 second.
Group by	Select the delimiter by which you want to group the calls in your report. You can choose from the following sorting options: • **Data Publisher**. Choose this option to sort the report by RADIUS gateway. • **Outbound Gateway** • **Inbound Gateway** • **None**. Choose this option to combine all calls into a single group.

Parameter	How to Set It
Show time details by	Select the time details you want to show for each group of calls. You can choose from the following detail options: • **Hour of Day** • **Day of Week** • **Day of Month** • **None**. If you select None, no time details are shown.
Thresholds	
Threshold - Good-Acceptable percent jitter loss	Specify the percentage below which the jitter loss is acceptable and equal to or above which the jitter loss is good. The default is 0.5%.
Threshold - Acceptable-Poor percent jitter loss	Specify the percentage below which the jitter loss is poor and above which the jitter loss is acceptable. The default is 1.0%.
Report Settings	
Include parameter help card?	Set to **y** to include a table in the report that lists parameter settings for the report script. The default is y.
Include table?	Set to **y** to include a table of data stream values in the report. The default is y.
Include chart?	Set to **y** to include a chart of data stream values in the report. The default is y.
Select chart style	Define the graphic properties for the charts in your report. The default style is Bar_Stacked. **NOTE:** To create a chart that indicates the percentage for each category, select **Pie**.
Select output folder	Set parameters for the output folder. The default folder name is CallDataJitterLoss.
Add job ID to output folder name?	Set to **y** to append the job ID to the name of the output folder. The default is n. A job ID is helpful for making the correlation between a specific instance of a Report script and the corresponding report.
Select properties	Set miscellaneous report properties as desired. The default report name is Call Jitter Loss.
Add time stamp to title?	Set to **y** to append a time stamp to the title of the report, making each title unique. The default is n. The time stamp is made up of the date and time the report was generated. Adding a time stamp is useful in order to run consecutive iterations of the same report without overwriting previous output.
Event Notification	
Raise event if report succeeds?	Set to **y** to raise an event if the report is successfully generated. The default is y.
Event severity when report succeeds	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report is successfully generated. The default is 35.
Event severity when report has no data	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report contains no data. The default is 25.
Event severity when report fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report cannot be generated. The default is 5.

17.19 Report_CallMOS

Use this Knowledge Script to categorize calls as having good, acceptable, or poor MOS or R-value based on thresholds you set.

Calls for which a MOS cannot be calculated are categorized as having "no data." In addition, a MOS is not calculated for calls that are not completed.

MOS is calculated by AppManager (using the E-model) for H.323 RADIUS Data Sources; it is calculated by Cisco (using a Cisco algorithm) for Unified Communications Manager Data Sources.

NOTE: Unlike other modules, for the Call Data Analysis module, the Report agent pulls data from the Data Warehouse rather than from the AppManager repository. The Report agent uses Windows authentication to access the Data Warehouse.

17.19.1 Resource Object

Report agent

17.19.2 Default Schedule

By default, this script runs once.

17.19.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Data Source	
Select data source(s)	Select the data for your report by **Type**, **View Name**, **Data Warehouse**, or **Data Source**.
Select time range	Select a **Specific** or **Sliding** date/time range from which the report should pull data. The default is Sliding.
Minimum duration	Specify the minimum duration filter for calls selected by the script. Calls with a duration of less than the minimum will not be included in the report, even if all other criteria are satisfied. The default is 1 second. **NOTE:** Calls that are not completed (i.e., have a duration of 0 seconds) do not generate MOS data. Therefore, the minimum duration default is 1 second.

Parameter	How to Set It
Group by	Select the delimiter by which you want to group the calls in your report. You can choose from the following sorting options: • **Data Publisher**. Choose this option to sort the report by RADIUS gateway or Communications Manager Publisher. • **Calling Partition** • **Called Partition** • **Calling Location** • **Called Location** • **Outbound Trunk Group** • **Inbound Trunk Group** • **Outbound Gateway** • **Inbound Gateway** • **CallManager Cluster** • **None**. Choose this option to combine all calls into a single group.
Show time details by	Select the time details you want to show for each group of calls. You can choose from the following detail options: • **Hour of Day** • **Day of Week** • **Day of Month** • **None**. If you select None, no time details are shown.
Thresholds	
Metric	Select whether to analyze call **MOS** or **R-value**. The R-value is calculated from the MOS score. For more information, see "Reviewing Call Quality Metrics for Gateways and Routers" on page 699. If your Data Source is a Communications Manager, do *not* select R-value. Communications Managers provide only a Listening MOS value; an R-value cannot be accurately calculated from a Listening MOS value.
Threshold - Good-Acceptable	Specify the MOS score below which a call is acceptable and equal to or above which a call is good. The default is 4.03.
Threshold - Acceptable-Poor	Specify the MOS score below which a call is poor and above which a call is acceptable. The default is 3.6.
Report Settings	
Include parameter help card?	Set to **y** to include a table in the report that lists parameter settings for the report script. The default is y.
Include table?	Set to **y** to include a table of data stream values in the report. The default is y.
Include chart?	Set to **y** to include a chart of data stream values in the report. The default is y.
Select chart style	Define the graphic properties for the charts in your report. The default style is Bar_Stacked. **NOTE:** To create a chart that indicates the percentage for each category, select **Pie**.
Select output folder	Set parameters for the output folder. The default folder name is CallDataMOS.

Parameter	How to Set It
Add job ID to output folder name?	Set to **y** to append the job ID to the name of the output folder. The default is n. A job ID is helpful for making the correlation between a specific instance of a Report script and the corresponding report.
Select properties	Set miscellaneous report properties as desired. The default report name is Call MOS.
Add time stamp to title?	Set to **y** to append a time stamp to the title of the report, making each title unique. The default is y. The time stamp is made up of the date and time the report was generated. Adding a time stamp is useful in order to run consecutive iterations of the same report without overwriting previous output.
Event Notification	
Raise event if report succeeds?	Set to **y** to raise an event if the report is successfully generated. The default is y.
Event severity when report succeeds	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report is successfully generated. The default is 35.
Event severity when report has no data	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report contains no data. The default is 25.
Event severity when report fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report cannot be generated. The default is 5.

17.20 Report_CallPacketLoss

Use this Knowledge Script to categorize calls as having a good, acceptable, or poor packet loss percentage based on thresholds you set. Calls that do not have a packet loss measurement are categorized as having "no data."

NOTE: Unlike other modules, for the Call Data Analysis module, the Report agent pulls data from the Data Warehouse rather than from the AppManager repository. The Report agent uses Windows authentication to access the Data Warehouse.

17.20.1 Resource Object

Report agent

17.20.2 Default Schedule

By default, this script runs once.

17.20.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Data Source	
Select data source(s)	Select the data for your report by **View Name**, **Data Warehouse**, or **Data Source**.
Select time range	Select a **Specific** or **Sliding** date/time range from which the report should pull data. The default is Sliding.
Minimum duration	Specify the minimum duration filter for calls selected by the script. Calls with a duration of less than the minimum will not be included in the report, even if all other criteria are satisfied. The default is 1 second. **NOTE:** Calls that are not completed (i.e., have a duration of 0 seconds) do not generate packet loss data. Therefore, the minimum duration default is 1 second.

Parameter	How to Set It
Group by	Select the delimiter by which you want to group the calls in your report. You can choose from the following sorting options: • **Data Publisher**. Choose this option to sort the report by the entity that generates the data: Communications Manager Publisher, Unified Communications Manager primary server, or RADIUS gateway. • **Calling Partition** (applies to Communications Manager Data Sources) • **Called Partition** (applies to Communications Manager Data Sources) • **Calling Location** (applies to Communications Manager Data Sources) • **Called Location** (applies to Communications Manager Data Sources) • **Outbound Trunk Group** (applies to Communications Manager Data Sources) • **Inbound Trunk Group** (applies to Communications Manager Data Sources) • **Outbound Gateway** (applies to all Data Sources) • **Inbound Gateway** (applies to all Data Sources) • **CallManager Cluster**. This option provides the same sorting results as Data Publisher. This option is maintained in the script to provide backwards compatibility to older versions of AppManager for Call Data Analysis. • **None**. Choose this option to combine all calls into a single group. **NOTE:** If your *Select data source(s)* and *Group by* selections are incompatible (perhaps you selected an H.323 data source and a Communications Manager grouping), the report ignores your *Group by* selection and uses the default selection, which is Data Publisher.
Show time details by	Select the time details you want to show for each group of calls. You can choose from the following detail options: • **Hour of Day** • **Day of Week** • **Day of Month** • **None**. If you select None, no time details are shown.
Thresholds	
Threshold - Good-Acceptable percent packet loss	Specify the value below which the call is acceptable and equal to or above which the call is good. The default is 0.5%.
Threshold - Acceptable-Poor percent packet loss	Specify the value below which the call is poor and above which the call is acceptable. The default is 1.0%.
Report Settings	
Include parameter help card?	Set to **y** to include a table in the report that lists parameter settings for the report script. The default is y.
Include table?	Set to **y** to include a table of data stream values in the report. The default is y.
Include chart?	Set to **y** to include a chart of data stream values in the report. The default is y.
Select chart style	Define the graphic properties for the charts in your report. The default style is Bar_Stacked.
Select output folder	Set parameters for the output folder. The default folder name is CallDataPacketLoss.

Parameter	How to Set It
Add job ID to output folder name?	Set to **y** to append the job ID to the name of the output folder. The default is n. A job ID is helpful for making the correlation between a specific instance of a Report script and the corresponding report.
Select properties	Set miscellaneous report properties as desired. The default report name is Call Packet Loss.
Add time stamp to title?	Set to **y** to append a time stamp to the title of the report, making each title unique. The default is n. The time stamp is made up of the date and time the report was generated. Adding a time stamp is useful in order to run consecutive iterations of the same report without overwriting previous output.
Event Notification	
Raise event if report succeeds?	Set to **y** to raise an event if the report is successfully generated. The default is y.
Event severity when report succeeds	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report is successful. The default is 35.
Event severity when report has no data	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report contains no data. The default is 25.
Event severity when report fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report fails. The default is 5.

17.21 Report_CallQualityByPhone

Use this Knowledge Script to identify the directory numbers (extensions) experiencing problems with call quality. AppManager calculates call metrics for calls in which the specified directory number originated the call and for calls in which the specified directory number was the destination.

- *Jitter* is an estimate of the statistical variance of the RTP data packet interarrival time, measured in milliseconds and expressed as an unsigned integer. Interarrival jitter is the mean deviation (smoothed absolute value) of the difference in packet spacing at the receiver compared to the sender for a pair of packets.
- *Latency* is the average value of the difference between the time stamp indicted by the senders of the messages and the timestamp of the receivers, measured when the messages are received.
- *MOS* (Mean Opinion Score) is an overall score representing the quality of a call. The MOS is a number between 1 and 5. A MOS of 5 is excellent; a MOS of 1 is unacceptably bad. AppManager uses the MOS Cisco has already calculated using its own algorithm.
- *Packet loss* equals the percentage of data packets lost since the beginning of reception. This number is calculated based on the number of packets expected and the number of packets actually received. The number of packets received includes those that were late or duplicates. Packets that arrive late are not counted as lost; the presence of duplicate packets could result in a negative lost data amount.

You can sort the rows in this report according to its various columns:

- Directory Number
- Duration of Originated Calls
- Average MOS
- Average Jitter
- Average Latency
- Average Packet Loss
- Duration of All Calls
- Success Rate
- Worst MOS
- Worst Jitter
- Worst Latency
- Worst Packet Loss

You can select only Unified Communications Manager Data Sources for this report. H.323 gateways cannot provide the required list of configured directory numbers.

NOTE: Unlike other modules, for the Call Data Analysis module, the Report agent pulls data from the Data Warehouse rather than from the AppManager repository. The Report agent uses Windows authentication to access the Data Warehouse.

17.21.1 Resource Object

Report agent

17.21.2 Default Schedule

By default, this script runs once.

17.21.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Data Source	
Select data source	Select the data for your report by **View Name**, **Data Warehouse**, or **Data Source**.
Select time range	Select a **Specific** or **Sliding** date/time range from which the report should pull data. The default is Sliding.
Minimum duration	Specify the minimum duration filter for calls selected by the script. The default is 0 seconds.
Exclude these failure codes	Specify a list of termination codes (separated by commas) that are not to be considered failures. For more information, see "Termination Codes" on page 743. **NOTE:** Codes 0, 16, 31, 126, and 393216 are automatically excluded. They are normal termination codes. However, these codes may appear in events if the other side of the call has a failure code that has not been excluded.
Search Criteria	
Note for entering search criteria: If you specify only the wildcard (*) for a field (such as calling number), AppManager matches *only* those calls that have a value for that field. Calls for which that field has no value (i.e., is NULL) will not be matched. For example, if you specify * in the *Calling partition name* parameter, the search matches only those calls that have some partition name configured. To match all calls (including calls that have no value for the selected field), leave the search criteria parameter blank.	
Directory number	Specify the directory numbers for which you want to identify call quality problems.
Device name	Specify the device names for which you want to identify call quality problems.
Device IP address	Specify the IP address of the devices you want to find. Use one of the following formats: • Single dotted-decimal IP address, such as 10.41.2.31 • Dotted-decimal IP address that includes a wildcard, such as 10.41.*.*, which would search for all IP addresses in the range of 10.41.0.0 to 10.41.255.255. • Range of dotted-decimal IP addresses separated by a hyphen, such as 10.41.2.31-10.41.2.41. The first address indicates the beginning of the range; the second IP address marks the end of the range.
Device location name	Specify the names of the device locations for which you want to identify call quality problems. Use the location configured on the Unified Communications Manager.
Partition name	Specify the partition names for which you want to identify call quality problems.
Report Settings	
Order rows by?	Select the column by which you want to sort the rows in the report.
MOS type?	Select whether to display **Average** or **Minimum** MOS in your report. • Average MOS is the running average of scores observed since the beginning of a call. • Minimum MOS is the minimum score observed since the beginning of a call, and represents the worst-sounding eight-second interval.
Include parameter help card?	Set to **y** to include a table in the report that lists parameter settings for the report script. The default is y.

Parameter	How to Set It
Select output folder	Set parameters for the output folder. The default folder name is CallQualityByPhone.
Add job ID to output folder name?	Set to **y** to append the job ID to the name of the output folder. The default is n. A job ID is helpful for making the correlation between a specific instance of a Report script and the corresponding report.
Select properties	Set miscellaneous report properties as desired. The default report name is Call Quality By Phone.
Add time stamp to title?	Set to **y** to append a time stamp to the title of the report, making each title unique. The default is n. The time stamp is made up of the date and time the report was generated. Adding a time stamp is useful in order to run consecutive iterations of the same report without overwriting previous output.
Event Notification	
Raise event if report succeeds?	Set to **y** to raise an event when the report is successfully generated. The default is y.
Event severity when report succeeds	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report is successful. The default is 35.
Event severity when report has no data	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report contains no data. The default is 25.
Event severity when report fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report fails. The default is 5.

17.22 Report_CallSuccessRate

Use this Knowledge Script to determine the success rate of calls recorded with the selected Data Source. A successful call is determined by the call's disconnect cause code.

NOTE: Unlike other modules, for the Call Data Analysis module, the Report agent pulls data from the Data Warehouse rather than from the AppManager repository. The Report agent uses Windows authentication to access the Data Warehouse.

17.22.1 Resource Object

Report agent

17.22.2 Default Schedule

By default, this script runs once.

17.22.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Data Source	
Select data source(s)	Select the data for your report by **View Name**, **Data Warehouse**, or **Data Source**.
Select time range	Select a **Specific** or **Sliding** date/time range from which the report should pull data. The default is Sliding.

Parameter	How to Set It
Group by	Select the delimiter by which you want to group the calls in your report. You can choose from the following sorting options: • **Data Publisher**. Choose this option to sort the report by the entity that generates the data: Communications Manager Publisher, Unified Communications Manager primary server, or RADIUS gateway. • **Calling Partition** (applies to Communications Manager Data Sources) • **Called Partition** (applies to Communications Manager Data Sources) • **Calling Location** (applies to Communications Manager Data Sources) • **Called Location** (applies to Communications Manager Data Sources) • **Outbound Trunk Group** (applies to Communications Manager Data Sources) • **Inbound Trunk Group** (applies to Communications Manager Data Sources) • **Outbound Gateway** (applies to all Data Sources) • **Inbound Gateway** (applies to all Data Sources) • **CallManager Cluster**. This option provides the same sorting results as Data Publisher. This option is maintained in the script to provide backwards compatibility to older versions of AppManager for Call Data Analysis. • None. Choose this option to combine all calls into a single group. **NOTE:** If your *Select data source(s)* and *Group by* selections are incompatible (perhaps you selected an H.323 data source and a Communications Manager grouping), the report ignores your *Group by* selection and uses the default selection, which is Data Publisher.
Show time details by	Select the time details you want to show for each group of calls. You can choose from the following detail options: • **Hour of Day** • **Day of Week** • **Day of Month** • **None**. If you select None, no time details are shown.
Exclude these failure codes	Specify a list of termination codes (separated by commas) that are not to be considered failures. For more information, see "Termination Codes" on page 743. **NOTE:** Codes 0, 16, 31, 126, and 393216 are automatically excluded. They are normal termination codes. However, these codes may appear in events if the other side of the call has a failure code that has not been excluded.
Report Settings	
Include parameter help card?	Set to **y** to include a table in the report that lists parameter settings for the report script. The default is y.
Include table?	Set to **y** to include a table of data stream values in the report. The default is y.
Include chart?	Set to **y** to include a chart of data stream values in the report. The default is y.
Select chart style	Define the graphic properties for the charts in your report. The default style is Bar.
Select output folder	Set parameters for the output folder. The default folder name is CallDataSuccessRate.

Parameter	How to Set It
Add job ID to output folder name?	Set to **y** to append the job ID to the name of the output folder. The default is n. A job ID is helpful for making the correlation between a specific instance of a Report script and the corresponding report.
Select properties	Set miscellaneous report properties as desired. The default report name is Call Success Rate.
Add time stamp to title?	Set to **y** to append a time stamp to the title of the report, making each title unique. The default is n. The time stamp is made up of the date and time the report was generated. Adding a time stamp is useful in order to run consecutive iterations of the same report without overwriting previous output.
Event Notification	
Raise event if report succeeds?	Set to **y** to raise an event when the report is successfully generated. The default is y.
Event severity when report succeeds	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report is successful. The default is 35.
Event severity when report has no data	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report contains no data. The default is 25.
Event severity when report fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report fails. The default is 5.

17.23 Report_CallTraffic

Use this Knowledge Script to summarize call traffic by call type.

NOTE: Unlike other modules, for the Call Data Analysis module, the Report agent pulls data from the Data Warehouse rather than from the AppManager repository. The Report agent uses Windows authentication to access the Data Warehouse.

17.23.1 Resource Object

Report agent

17.23.2 Default Schedule

By default, this script runs once.

17.23.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Data Source	
Select data source(s)	Select the data for your report by **View Name**, **Data Warehouse**, or **Data Source**.
Select time range	Select a **Specific** or **Sliding** date/time range from which the report should pull data. The default is Sliding.
Minimum duration	Specify the minimum duration filter for calls selected by the script. Calls with a duration of less than the minimum will not be included in the report, even if all other criteria are satisfied. The default is 0 seconds.

Parameter	How to Set It
Group by	Select the delimiter by which you want to group the calls in your report. You can choose from the following sorting options: • **Data Publisher**. Choose this option to sort the report by the entity that generates the data: Communications Manager Publisher, Unified Communications Manager primary server, or RADIUS gateway. • **Calling Partition** (applies to Communications Manager Data Sources) • **Called Partition** (applies to Communications Manager Data Sources) • **Calling Location** (applies to Communications Manager Data Sources) • **Called Location** (applies to Communications Manager Data Sources) • **Outbound Trunk Group** (applies to Communications Manager Data Sources) • **Inbound Trunk Group** (applies to Communications Manager Data Sources) • **Outbound Gateway** (applies to all Data Sources) • **Inbound Gateway** (applies to all Data Sources) • **CallManager Cluster**. This option provides the same sorting results as Data Publisher. This option is maintained in the script to provide backwards compatibility to older versions of AppManager for Call Data Analysis. • **None**. Choose this option to combine all calls into a single group. **NOTE:** If your *Select data source(s)* and *Group by* selections are incompatible (perhaps you selected an H.323 data source and a Communications Manager grouping), the report ignores your *Group by* selection and uses the default selection, which is Data Publisher.
Report Settings	
Include parameter help card?	Set to **y** to include a table in the report that lists parameter settings for the report script. The default is y.
Include table?	Set to **y** to include a table of data stream values in the report. The default is y.
Include chart?	Set to **y** to include a chart of data stream values in the report. The default is y.

Show duration in Erlangs or seconds?	Select whether to display call duration in **Erlangs** or **Seconds**. The default is Erlangs.
	Also known as a traffic unit, an Erlang is a measurement of traffic load during the busy hour, and is based on having 3600 seconds (60 minutes or one hour) of calls on the same circuit, trunk, or port. (In other words, one circuit is busy for one hour regardless of the number of calls or the average length of calls). For example, if a call center received 30 six-minutes calls in the busy hour, it received 180 call minutes, or three Erlangs. If a call center received 100 calls that averaged 36 seconds in the busy hour, it received 3600 call seconds or one Erlang.
	You can use the following formula to calculate an Erlang value:
	`Traffic in Erlangs =`
	`(Number of calls in the busy hour) * (AHT seconds)/3600`

Select chart style	Define the graphic properties for the charts in your report. The default style is Bar_Stacked. **NOTE:** To create a chart that indicates the percentage of each type of call, select **Pie**.

Parameter	How to Set It
Select output folder	Set parameters for the output folder. The default folder name is CallDataTraffic.
Add job ID to output folder name?	Set to **y** to append the job ID to the name of the output folder. The default is n. A job ID is helpful for making the correlation between a specific instance of a Report script and the corresponding report.
Select properties	Set miscellaneous report properties as desired. The default report name is Call Traffic.
Add time stamp to title?	Set to **y** to append a time stamp to the title of the report, making each title unique. The default is n. The time stamp is made up of the date and time the report was generated. Adding a time stamp is useful in order to run consecutive iterations of the same report without overwriting previous output.
Event Notification	
Raise event if report succeeds?	Set to **y** to raise an event when the report is successfully generated. The default is y.
Event severity when report succeeds	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report is successful. The default is 35.
Event severity when report has no data	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report contains no data. The default is 25.
Event severity when report fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report fails. The default is 5.

17.24 Report_CallVolume

Use this Knowledge Script to summarize the number and duration of calls recorded with the selected Data Source.

In this report, calls that have an originating gateway and a terminating gateway that are different are associated with the originating gateway. For a clearer view of incoming and outgoing calls on a per-gateway basis, use the Report_TrunkGroupByHour report.

NOTE: Unlike other modules, for the Call Data Analysis module, the Report agent pulls data from the Data Warehouse rather than from the AppManager repository. The Report agent uses Windows authentication to access the Data Warehouse.

17.24.1 Resource Object

Report agent

17.24.2 Default Schedule

By default, this script runs once.

17.24.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Data Source	
Select data source(s)	Select the data for your report by **View Name**, **Data Warehouse**, or **Data Source**.
Select time range	Select a **Specific** or **Sliding** date/time range from which the report should pull data. The default is Sliding.
Minimum duration	Specify the minimum duration filter for calls selected by the script. Calls with a duration of less than the minimum will not be included in the report, even if all other criteria are satisfied. The default is 0 seconds.

Parameter	How to Set It
Group by	Select the delimiter by which you want to group the calls in your report. You can choose from the following sorting options: • **Data Publisher**. Choose this option to sort the report by the entity that generates the data: Communications Manager Publisher, Unified Communications Manager primary server, or RADIUS gateway. • **Calling Partition** (applies to Communications Manager Data Sources) • **Called Partition** (applies to Communications Manager Data Sources) • **Calling Location** (applies to Communications Manager Data Sources) • **Called Location** (applies to Communications Manager Data Sources) • **Outbound Trunk Group** (applies to Communications Manager Data Sources) • **Inbound Trunk Group** (applies to Communications Manager Data Sources) • **Outbound Gateway** (applies to all Data Sources) • **Inbound Gateway** (applies to all Data Sources) • **CallManager Cluster**. This option provides the same sorting results as Data Publisher. This option is maintained in the script to provide backwards compatibility to older versions of AppManager for Call Data Analysis. • **None**. Choose this option to combine all calls into a single group. **NOTE:** If your *Select data source(s)* and *Group by* selections are incompatible (for instance, if you selected an H.323 data source and a Communications Manager grouping), the report ignores your *Group by* selection and uses the default selection, which is Data Publisher.
Show time details by	Select the time details you want to show for each group of calls. Choose from the following detail options: • **Hour of Day** • **Day of Week** • **Day of Month** • **None**. If you select None, no time details are shown.
Group time details based on	Select the way in which you want to group the time details for calls. Choose one of the following: • **Start time** - to group entire calls by the time periods in which the calls start. For example, you choose to group calls by Hour of Day. Five calls begin during the 12:00 hour. Regardless of the duration of the calls, the report will show five calls during the 12:00 hour. • **Call duration** - to split calls into multiple groups based on the duration of the calls. For example, you choose to group calls by Hour of Day. Five calls begin during the 12:00 hour. Three of the calls complete during the 12:00 hour, two calls complete during the 1:00 hour, and one call that began at 11:45 completes during the 12:00 hour. The report will show four calls during the 12:00 hour and two calls during the 1:00 hour.
Report Settings	
Include parameter help card?	Set to **y** to include a table in the report that lists parameter settings for the report script. The default is y.
Include table?	Set to **y** to include a table of data stream values in the report. The default is y.

Parameter	How to Set It
Include chart?	Set to **y** to include a chart of data stream values in the report. The default is y.
Units for chart	Select the unit of measurement that should appear on the Y axis of the chart: **Duration** or **Number Of Calls**. The default is Number of Calls. If you select Duration, the duration unit measurement is determined by the value you select in the *Show duration in Erlangs or seconds?* parameter.

Show duration in Erlangs or seconds?	Select whether you want the duration measurement to display in Erlangs or seconds. The default is Erlangs.
	
	Also known as a traffic unit, an Erlang is a measurement of traffic load during the busy hour, and is based on having 3600 seconds (60 minutes or one hour) of calls on the same circuit, trunk, or port. (In other words, one circuit is busy for one hour regardless of the number of calls or the average length of calls). For example, if a call center received 30 six-minutes calls in the busy hour, it received 180 call minutes, or three Erlangs. If a call center received 100 calls that averaged 36 seconds in the busy hour, it received 3600 call seconds or one Erlang.
	
	You can use the following formula to calculate an Erlang value:
	
	`Traffic in Erlangs =`
	`(Number of calls in the busy hour) * (AHT seconds)/3600`

Select chart style	Define the graphic properties for the charts in your report. The default style is Bar.
Select output folder	Set parameters for the output folder. The default folder name is CallDataVolume.
Add job ID to output folder name?	Set to **y** to append the job ID to the name of the output folder. The default is n. A job ID is helpful for making the correlation between a specific instance of a Report script and the corresponding report.
Select properties	Set miscellaneous report properties as desired. The default report name is Call Volume.
Add time stamp to title?	Set to **y** to append a time stamp to the title of the report, making each title unique. The default is n. The time stamp is made up of the date and time the report was generated. Adding a time stamp is useful in order to run consecutive iterations of the same report without overwriting previous output.
Event Notification	
Raise event if report succeeds?	Set to **y** to raise an event when the report is successfully generated. The default is y.
Event severity when report succeeds	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report is successful. The default is 35.
Event severity when report has no data	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report contains no data. The default is 25.
Event severity when report fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report fails. The default is 5.

17.25 Report_CallVolumeEDS

Use this Knowledge Script to summarize the number and duration of calls recorded with the selected Data Source.

In this report, calls that have an originating gateway and a terminating gateway that are different are associated with the originating gateway. For a clearer view of incoming and outgoing calls on a per-gateway basis, use the Report_TrunkGroupByHour report.

NOTE: Unlike other modules, for the Call Data Analysis module, the Report agent pulls data from the Data Warehouse rather than from the AppManager repository. The Report agent uses Windows authentication to access the Data Warehouse.

17.25.1 Resource Object

Report agent

17.25.2 Default Schedule

By default, this script runs once.

17.25.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Data Source	
Select data source(s)	Select the data for your report by **View Name**, **Data Warehouse**, or **Data Source**.
Select time range	Select a **Specific** or **Sliding** date/time range from which the report should pull data. The default is Sliding.
Minimum duration	Specify the minimum duration filter for calls selected by the script. Calls with a duration of less than the minimum will not be included in the report, even if all other criteria are satisfied. The default is 0 seconds.

Parameter	How to Set It
Group by	Select the delimiter by which you want to group the calls in your report. You can choose from the following sorting options: • **Data Publisher**. Choose this option to sort the report by the entity that generates the data: Communications Manager Publisher, Unified Communications Manager primary server, or RADIUS gateway. • **Calling Partition** (applies to Communications Manager Data Sources) • **Called Partition** (applies to Communications Manager Data Sources) • **Calling Location** (applies to Communications Manager Data Sources) • **Called Location** (applies to Communications Manager Data Sources) • **Outbound Trunk Group** (applies to Communications Manager Data Sources) • **Inbound Trunk Group** (applies to Communications Manager Data Sources) • **Outbound Gateway** (applies to all Data Sources) • **Inbound Gateway** (applies to all Data Sources) • **CallManager Cluster**. This option provides the same sorting results as Data Publisher. This option is maintained in the script to provide backwards compatibility to older versions of AppManager for Call Data Analysis. • **None**. Choose this option to combine all calls into a single group. **NOTE:** If your *Select data source(s)* and *Group by* selections are incompatible (for instance, if you selected an H.323 data source and a Communications Manager grouping), the report ignores your *Group by* selection and uses the default selection, which is Data Publisher.
Show time details by	Select the time details you want to show for each group of calls. Choose from the following detail options: • **Hour of Day** • **Day of Week** • **Day of Month** • **None**. If you select None, no time details are shown.
Group time details based on	Select the way in which you want to group the time details for calls. Choose one of the following: • **Start time** - to group entire calls by the time periods in which the calls start. For example, you choose to group calls by Hour of Day. Five calls begin during the 12:00 hour. Regardless of the duration of the calls, the report will show five calls during the 12:00 hour. • **Call duration** - to split calls into multiple groups based on the duration of the calls. For example, you choose to group calls by Hour of Day. Five calls begin during the 12:00 hour. Three of the calls complete during the 12:00 hour, two calls complete during the 1:00 hour, and one call that began at 11:45 completes during the 12:00 hour. The report will show four calls during the 12:00 hour and two calls during the 1:00 hour.
Report Settings	
Include parameter help card?	Set to **y** to include a table in the report that lists parameter settings for the report script. The default is y.
Include table?	Set to **y** to include a table of data stream values in the report. The default is y.

Parameter	How to Set It
Include chart?	Set to **y** to include a chart of data stream values in the report. The default is y.
Units for chart	Select the unit of measurement that should appear on the Y axis of the chart: **Duration** or **Number Of Calls**. The default is Number of Calls. If you select Duration, the duration unit measurement is determined by the value you select in the *Show duration in Erlangs or seconds?* parameter.

Show duration in Erlangs or seconds?	Select whether you want the duration measurement to display in Erlangs or seconds. The default is Erlangs.
	
	Also known as a traffic unit, an Erlang is a measurement of traffic load during the busy hour, and is based on having 3600 seconds (60 minutes or one hour) of calls on the same circuit, trunk, or port. (In other words, one circuit is busy for one hour regardless of the number of calls or the average length of calls). For example, if a call center received 30 six-minutes calls in the busy hour, it received 180 call minutes, or three Erlangs. If a call center received 100 calls that averaged 36 seconds in the busy hour, it received 3600 call seconds or one Erlang.
	
	You can use the following formula to calculate an Erlang value:
	
	`Traffic in Erlangs =`
	`(Number of calls in the busy hour) * (AHT seconds)/3600`

Select chart style	Define the graphic properties for the charts in your report. The default style is Bar.
Select output folder	Set parameters for the output folder. The default folder name is CallDataVolume.
Add job ID to output folder name?	Set to **y** to append the job ID to the name of the output folder. The default is n. A job ID is helpful for making the correlation between a specific instance of a Report script and the corresponding report.
Select properties	Set miscellaneous report properties as desired. The default report name is Call Volume.
Add time stamp to title?	Set to **y** to append a time stamp to the title of the report, making each title unique. The default is n. The time stamp is made up of the date and time the report was generated. Adding a time stamp is useful in order to run consecutive iterations of the same report without overwriting previous output.
Event Notification	
Raise event if report succeeds?	Set to **y** to raise an event when the report is successfully generated. The default is y.
Event severity when report succeeds	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report is successful. The default is 35.
Event severity when report has no data	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report contains no data. The default is 25.
Event severity when report fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report fails. The default is 5.

17.26 Report_CCME_StatsByEPhone

Use this Knowledge Script to summarize the call statistics for Cisco Communications Manager Express phones (ephones) based on configuration information retrieved by the CCME_GetConfig Knowledge Script. You must run GetConfig and the Data Collection job before you can run StatsByEPhone.

This report can summarize the following call statistics:

- Communications Manager Express
- Total Duration
- Duration of Originated Calls
- Completed Calls
- Completion Rate
- Total Calls
- Originated Calls
- Failed Calls
- Success Rate

You can sort the rows in this report according to its various columns:

- Directory Number
- Duration of Originated Calls
- Completion Rate
- Duration of All Calls
- Number of Originated Calls
- Success Rate

NOTE: Unlike other modules, for the Call Data Analysis module, the Report agent pulls data from the Data Warehouse rather than from the AppManager repository. The Report agent uses Windows authentication to access the Data Warehouse.

17.26.1 Resource Object

Report agent

17.26.2 Default Schedule

By default, this script runs once.

17.26.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Data Source	
Select data source	Select the data for your report by **View Name**, **Data Warehouse**, or **Data Source**. You may select only one H.323 RADIUS data source.
Select time range	Select a **Specific** or **Sliding** date/time range from which the report should pull data. The default is Sliding.

Parameter	How to Set It
Minimum duration	Specify the minimum duration filter for calls selected by the script. The default is 0 seconds.
Exclude these failure codes	Type a list of termination codes (separated by commas) that are not to be considered failures. For more information, see "Termination Codes" on page 743. **NOTE:** Codes 0, 16, 31, 126, and 393216 are automatically excluded. They are normal termination codes. However, these codes may appear in events if the other side of the call has a failure code that has not been excluded.
Search Criteria	
Note for entering search criteria: If you specify only the wildcard (*) for a field (such as calling number), AppManager matches *only* those calls that have a value for that field. Calls for which that field has no value (i.e., is NULL) will not be matched. For example, if you specify * in the *Calling partition name* parameter, the search matches only those calls that have some partition name configured. To match all calls (including calls that have no value for the selected field), leave the search criteria parameter blank.	
Gateway name	Specify the name of the Communications Manager Express gateway for which you want to gather call statistics. Leave this field blank to gather statistics for *all* Communications Manager Express gateways.
Directory number	Specify the directory number for which you want to gather call statistics.
Device name	Specify the name of the device for which you want to gather call statistics.
Device IP address	Specify the IP addresses of the devices you want to find. Use one of the following formats: • Single dotted-decimal IP address, such as 10.41.2.31 • Dotted-decimal IP address that includes a wildcard, such as 10.41.*.*, which would search for all IP addresses in the range of 10.41.0.0 to 10.41.255.255. • Range of dotted-decimal IP addresses separated by a hyphen, such as 10.41.2.31-10.41.2.41. The first address indicates the beginning of the range; the second IP address marks the end of the range.
Report Settings	
Order rows by?	Select the column by which you want to sort the rows in the report. The default is DirectoryNumber.
Include parameter help card?	Set to **y** to include a table in the report that lists parameter settings for the report script. The default is y.
Select output folder	Set parameters for the output folder. The default folder name is CCME_StatsByEPhone.
Add job ID to output folder name?	Set to **y** to append the job ID to the name of the output folder. The default is n. A job ID is helpful for making the correlation between a specific instance of a Report script and the corresponding report.
Select properties	Set miscellaneous report properties as desired. The default report name is Cisco CME Call Statistics By EPhone.
Add time stamp to title?	Set to **y** to append a time stamp to the title of the report, making each title unique. The default is n. The time stamp is made up of the date and time the report was generated. Adding a time stamp is useful in order to run consecutive iterations of the same report without overwriting previous output.

Parameter	How to Set It
Event Notification	
Raise event if report succeeds?	Set to **y** to raise an event when the report is successfully generated. The default is y.
Event severity when report succeeds	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report is successful. The default is 35.
Event severity when report has no data	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report contains no data. The default is 25.
Event severity when report fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report fails. The default is 5.

17.27 Report_CCME_Summary

Use this Knowledge Script to summarize the following call statistics for Cisco Communications Manager Express gateways:

- Number of calls
- Completed calls
- Abandoned calls
- Completion rate
- Total duration
- Failed calls
- Success rate

By default, these statistics are broken down by incoming vs. outgoing calls from and to Communications Manager Express phones — details are shown for outgoing, incoming, and local Communications Manager Express calls.

In addition, you can choose to break down the statistics by Communications Manager Express calls to and from the PSTN vs. calls to and from the IP network. If you choose this option, details are shown for calls outgoing to the PSTN, outgoing to the IP, incoming from the PSTN, and incoming from the IP, and for local Communications Manager Express calls.

NOTE: Unlike other modules, for the Call Data Analysis module, the Report agent pulls data from the Data Warehouse rather than from the AppManager repository. The Report agent uses Windows authentication to access the Data Warehouse.

17.27.1 Resource Object

Report agent

17.27.2 Default Schedule

By default, this script runs once.

17.27.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Data Source	
Select data source	Select the data for your report by **View Name**, **Data Warehouse**, or **Data Source**. You may select only one H.323 RADIUS data source.
Select time range	Select a **Specific** or **Sliding** date/time range from which the report should pull data. The default is Sliding.
Gateway name	Specify the name of the Communications Manager Express gateway for which you want to gather call statistics. Leave this field blank to gather statistics for *all* Communications Manager Express gateways.

Parameter	How to Set It
Minimum duration	Specify the minimum duration filter for calls selected by the report. The default is 0 seconds.
Exclude these failure codes	Type a list of termination codes (separated by commas) that are not to be considered failures. For more information, see "Termination Codes" on page 743. **NOTE:** Codes 0, 16, 31, 126, and 393216 are automatically excluded. They are normal termination codes. However, these codes may appear in events if the other side of the call has a failure code that has not been excluded.
Report Settings	
Include parameter help card?	Set to **y** to include a table in the report that lists parameter settings for the report script. The default is y.
Include table?	Set to **y** to include a table of call statistics in the report. The default is y.
Include chart?	Set to **y** to include a chart of call statistics in the report. The default is y. If you choose to include a chart, use the *Select call statistic for chart* parameter to select the statistic you want to display in the chart.
Show breakdown of PSTN calls vs. IP calls?	Set to **y** to include a breakdown of statistics by Communications Manager Express calls to/from the PSTN vs. calls to/from the IP network. If you choose this option, details are shown for calls outgoing to the PSTN, outgoing to the IP, incoming from the PSTN, and incoming from the IP, and for local Communications Manager Express calls. The default is n.
Select call statistic for chart	Select the call statistic you want to display, per gateway, in a chart in the report. You can choose from: • **Number of Calls** (default) • **Duration** • **Success Rate** • **Completion Rate**

Show duration in Erlangs or seconds?	Select whether to display call duration in **Erlangs** or **Seconds**. The default is Erlangs.
	
	Also known as a traffic unit, an Erlang is a measurement of traffic load during the busy hour, and is based on having 3600 seconds (60 minutes or one hour) of calls on the same circuit, trunk, or port. (In other words, one circuit is busy for one hour regardless of the number of calls or the average length of calls). For example, if a call center received 30 six-minutes calls in the busy hour, it received 180 call minutes, or three Erlangs. If a call center received 100 calls that averaged 36 seconds in the busy hour, it received 3600 call seconds or one Erlang.
	
	You can use the following formula to calculate an Erlang value:
	
	`Traffic in Erlangs =`
	`(Number of calls in the busy hour) * (AHT seconds)/3600`

Select chart style	Define the graphic properties for the charts in your report. The default style is Bar.
Select output folder	Set parameters for the output folder. The default folder name is CCME_CallSummary.

Parameter	How to Set It
Add job ID to output folder name?	Set to **y** to append the job ID to the name of the output folder. The default is n. A job ID is helpful for making the correlation between a specific instance of a Report script and the corresponding report.
Select properties	Set miscellaneous report properties as desired. The default report name is Cisco CME Call Summary.
Add time stamp to title?	Set to **y** to append a time stamp to the title of the report, making each title unique. The default is n. The time stamp is made up of the date and time the report was generated. Adding a time stamp is useful in order to run consecutive iterations of the same report without overwriting previous output.
Event Notification	
Raise event if report succeeds?	Set to **y** to raise an event when the report is successfully generated. The default is y.
Event severity when report succeeds	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report is successful. The default is 35.
Event severity when report has no data	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report contains no data. The default is 25.
Event severity when report fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report fails. The default is 5.

17.28 Report_FrequentlyCalledNumbers

Use this Knowledge Script to display any destination phone numbers called frequently during a specified time range. The report contains three columns: Called Number, Total Calls, and Total Duration.

17.28.1 Identifying Toll Fraud

The concept of toll fraud encompasses two separate but related security problems: frequently called numbers and the inappropriate use of long-distance capabilities, such as overly long calls to foreign countries or 900 numbers.

You can use the Report_FrequentlyCalledNumbers Knowledge Script to discover whether any particular phone number is being called more often than seems reasonable. Perhaps a once-a-month call to a European client is acceptable, but ten calls in one week indicates a problem.

The Report_FrequentlyCalledNumbers Knowledge Script creates a table that identifies the destination number, the number of calls made to the destination number, and the total duration of all calls made to the destination number. You set the threshold for "too many" calls — the report will display data for every destination phone number that received more calls than that threshold. Then use the Report_CallDetail_CiscoCallMgr Knowledge Script to identify the originating phone number of all calls made to the phone number in question.

The CallDetail_CiscoCallMgr Knowledge Script can also help your efforts to identify overly long calls. For instance, while making rounds, a courier went from office to office, picked up a phone in a public area, dialed a premium number, and then left, leaving the call active. The companies were billed for several hours of charges to the premium number.

With the Report_CallDetail_CiscoCallMgr Knowledge Script, you can create a report that looks for trends in overly long calls. Set the *Maximum duration* parameter to the maximum length of an acceptable call. Acceptable durations will vary by company, but for this scenario, let us say ten minutes. The report will present a list of calls that exceed the ten-minute limit.

17.28.2 Resource Object

Report agent

17.28.3 Default Schedule

By default, this script runs once.

17.28.4 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Data Source	
Select data source	Select the data for your report by **View Name**, **Data Warehouse**, or **Data Source**.

Parameter	How to Set It
Select time range	Select a **Specific** or **Sliding** date/time range from which the report should pull data. The default is Sliding.
Search Criteria	
Called number pattern	Specify the phone number pattern you want to find. The pattern can include the * wildcard. For example, to search for external calls, type 9*. Leave this parameter blank to include all calls in the report, as long as all other criteria are satisfied.
Minimum duration of each call	Specify the minimum duration filter for calls selected by the script. Calls with a duration of less than the minimum will not be included in the report, even if all other criteria are satisfied. Accept the default of 0 to indicate no limit.
Minimum number of calls	Specify the minimum number of times a number must be called before it can be included in your report. For example, if you type 5, your report will include only those numbers called five or more times. The default is 2 calls.
Report Settings	
Maximum number of rows to return	Specify the maximum number of rows to include in the table in the report. The default is 1000 rows. **NOTE:** No matter how many rows you choose to include in the report, the report will indicate how many rows actually met your search criteria. This number may, and probably will, exceed the number of rows you choose to return.
Order rows by?	Select the delimiter by which you want to sort the calls in your report. You can choose from the following sorting options: • **Total Calls** (default) • **Total Duration** • **Called Number**

Show duration in Erlangs or seconds?	Select whether to display call duration in **Erlangs** or **Seconds**. The default is Seconds.
	
	Also known as a traffic unit, an Erlang is a measurement of traffic load during the busy hour, and is based on having 3600 seconds (60 minutes or one hour) of calls on the same circuit, trunk, or port. (In other words, one circuit is busy for one hour regardless of the number of calls or the average length of calls). For example, if a call center received 30 six-minutes calls in the busy hour, it received 180 call minutes, or three Erlangs. If a call center received 100 calls that averaged 36 seconds in the busy hour, it received 3600 call seconds or one Erlang.
	
	You can use the following formula to calculate an Erlang value:
	
	`Traffic in Erlangs =`
	`(Number of calls in the busy hour) * (AHT seconds)/3600`

Include parameter help card?	Set to **y** to include a table in the report that lists parameter settings for the report script. The default is y.
Select output folder	Set parameters for the output folder. The default folder name is FrequentlyCalledNumbers.

Parameter	How to Set It
Add job ID to output folder name?	Set to **y** to append the job ID to the name of the output folder. The default is n. A job ID is helpful for making the correlation between a specific instance of a Report script and the corresponding report.
Select properties	Set miscellaneous report properties as desired. The default report name is Frequently Called Numbers.
Add time stamp to title?	Set to **y** to append a time stamp to the title of the report, making each title unique. The default is n. The time stamp is made up of the date and time the report was generated. Adding a time stamp is useful in order to run consecutive iterations of the same report without overwriting previous output.
Event Notification	
Raise event if report succeeds?	Set to **y** to raise an event if the report is successfully generated. The default is y.
Event severity when report succeeds	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report is successful. The default is 35.
Event severity when report has no data	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report contains no data. The default is 25.
Event severity when report fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report fails. The default is 5.

17.29 Report_GatewayDialPeers

Use this Knowledge Script to summarize call statistics for the POTS (Plain Old Telephone System) and VoIP dial peers of the gateways included in the report. By default, these statistics include total calls, total duration, failed calls, and success rate. You can choose to include call quality statistics for VoIP dial peers.

A dial peer is the association of a dialed sequence of numbers with a device in a telephone network. In a POTS network, a dial peer maps to a specific voice port on a local router or gateway. In a VoIP network, a dial peer maps to a remote network device, such as a router, a gateway, or a Cisco Unified Communications Manager. There is a one-to-one correspondence between a dial peer and a call leg.

A call leg is a component of the accounting records generated by a Cisco H.323 gateway. A call leg represents a logical connection between the gateway and a telephony or IP endpoint. Each call processed through a gateway consists of one or more call legs.

17.29.1 Resource Object

Report agent

17.29.2 Default Schedule

By default, this script runs once.

17.29.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Data Source	
Select data source	Select the data for your report by **View Name**, **Data Warehouse**, or **Data Source**. You can select only one H.323 RADIUS Data Source.
Select time range	Select a **Specific** or **Sliding** date/time range from which the report should pull data. The default is Sliding.
Gateway name	Indicate the name of the gateway for which you want to summarize call statistics. Leave this field blank to summarize statistics for *all* gateways associated with the Data Source
Direction of calls	Select the direction of the calls for which you want to summarize statistics. Choose from **Inbound Only**, **Outbound Only**, or **Inbound and Outbound**. The default is Inbound and Outbound.
Type of dial peer	Select the dial peer for which you want to summarize call statistics. Choose from **POTS Only**, **VoIP Only**, or **POTS and VoIP**. The default is POTS and VoIP.
Minimum duration	Specify the minimum duration filter for calls selected by the script. Calls with a duration of less than the minimum will not be included in the report, even if all other criteria are satisfied. The default is 0 seconds.

Parameter	How to Set It
Exclude these failure codes	Specify a list of termination codes (separated by commas) you do not want to include in the report. In other words, any call that terminates with one of the listed codes will not be included in the report. For more information, see "Termination Codes" on page 743. **NOTE:** Codes 0, 16, 31, 126, and 393216 are automatically excluded. They are normal termination codes. However, these codes may appear in events if the other side of the call has a failure code that has not been excluded.
Report Settings	
Include quality metrics?	Select whether to include call quality metrics in the report. You can choose from **Metrics with a MOS**, **Metrics with an R-value**, or **No Metrics**. For more information, see "Reviewing Call Quality Metrics for Gateways and Routers" on page 699.

Show duration in Erlangs or seconds?	Select whether to display call duration in **Erlangs** or **Seconds**. The default is Seconds.
	
	Also known as a traffic unit, an Erlang is a measurement of traffic load during the busy hour, and is based on having 3600 seconds (60 minutes or one hour) of calls on the same circuit, trunk, or port. (In other words, one circuit is busy for one hour regardless of the number of calls or the average length of calls). For example, if a call center received 30 six-minutes calls in the busy hour, it received 180 call minutes, or three Erlangs. If a call center received 100 calls that averaged 36 seconds in the busy hour, it received 3600 call seconds or one Erlang.
	
	You can use the following formula to calculate an Erlang value:
	
	`Traffic in Erlangs =`
	`(Number of calls in the busy hour) * (AHT seconds)/3600`

Order rows by?	Select the delimiter by which you want to sort the calls in your report. You can choose from the following sorting options: • **Dial Peer** (default) • **Number of Calls** • **Duration of Calls** • **Success Rate**
Include parameter help card?	Set to **y** to include a table in the report that lists parameter settings for the report script. The default is y.
Select output folder	Set parameters for the output folder. The default folder name is GatewayDialPeers.
Add job ID to output folder name?	Set to **y** to append the job ID to the name of the output folder. The default is n. A job ID is helpful for making the correlation between a specific instance of a Report script and the corresponding report.
Select properties	Set miscellaneous report properties as desired. The default report name is Cisco Voice Gateway Dial Peers.
Add time stamp to title?	Set to **y** to append a time stamp to the title of the report, making each title unique. The default is n. The time stamp is made up of the date and time the report was generated. Adding a time stamp is useful in order to run consecutive iterations of the same report without overwriting previous output.

Parameter	How to Set It
Event Notification	
Raise event if report succeeds?	Set to **y** to raise an event if the report is successfully generated. The default is y.
Event severity when report succeeds	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report is successful. The default is 35.
Event severity when report has no data	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report contains no data. The default is 25.
Event severity when report fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report fails. The default is 5.

17.30 Report_TrunkGroupByHour

Use this Knowledge Script to display the trunk group or gateway volume by hour for the selected Cisco Unified Communications Manager clusters or to display the gateway, trunk group, or interface volume for the selected H.323 RADIUS Data Source. The report includes a breakdown of calls that are inbound, outbound, or both (tandem).

A Communications Manager trunk group points to a series of devices (gateways or intercluster trunks to remote Communications Managers) through which calls are to be routed.

An H.323 gateway trunk group consists of a set of interfaces on the gateway configured to belong to the trunk group.

NOTE: Unlike other modules, for the Call Data Analysis module, the Report agent pulls data from the Data Warehouse rather than from the AppManager repository. The Report agent uses Windows authentication to access the Data Warehouse.

17.30.1 Resource Object

Report agent

17.30.2 Default Schedule

By default, this script runs once.

17.30.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Data Source	
Select data source(s)	Select the data for your report by **Data Source Type**, **View Name**, **Data Warehouse**, and **Data Source**.
Select time range	Select a **Specific** or **Sliding** date/time range from which the report should pull data. The default is Sliding.
Show results by	Select whether to show results for **Trunk Groups**, **Gateways**, or **Interfaces**. The default is Trunk Groups. The Interfaces option is valid only for H.323 RADIUS Data Sources.
Gateway name	Use this parameter to specify which gateways to include in the report. Specify the name of the gateway you want to include in the report. To include multiple gateways, use the * as a wildcard character. For example, type `RAL*` to include the gateways named RAL001, RAL003, and RAL010. Leave this parameter blank to include all gateways. This parameter is valid only for H.323 RADIUS Data Sources.

Parameter	How to Set It
Minimum duration	Specify the minimum duration filter for calls selected by the script. Calls with a duration of less than the minimum will not be included in the report, even if all other criteria are satisfied. The default is 0 seconds.
Report Settings	
Include parameter help card?	Set to **y** to include a table in the report that lists parameter settings for the report script. The default is y.
Include table?	Set to **y** to include a table of data stream values in the report. The default is y.
Include chart?	Set to **y** to include a chart of data stream values in the report. The default is y.
Units for chart and peak hour calculation	Select the unit of measurement that should appear on the Y axis of the chart: **Duration** or **Number Of Calls**. The default is Number of Calls. If you select Duration, the duration unit measurement is determined by the value you select in the *Show duration in Erlangs or seconds?* parameter.

Show duration in Erlangs or seconds?	Select whether to display call duration in **Erlangs** or **Seconds**. The default is Erlangs.
	
	Also known as a traffic unit, an Erlang is a measurement of traffic load during the busy hour, and is based on having 3600 seconds (60 minutes or one hour) of calls on the same circuit, trunk, or port. (In other words, one circuit is busy for one hour regardless of the number of calls or the average length of calls). For example, if a call center received 30 six-minutes calls in the busy hour, it received 180 call minutes, or three Erlangs. If a call center received 100 calls that averaged 36 seconds in the busy hour, it received 3600 call seconds or one Erlang.
	
	You can use the following formula to calculate an Erlang value:
	
	`Traffic in Erlangs =`
	`(Number of calls in the busy hour) * (AHT seconds)/3600`

Select chart style	Define the graphic properties for the charts in your report. The default style is Bar_Stacked.
Select output folder	Set parameters for the output folder. The default folder name is TrunkGroupByHour.
Add job ID to output folder name?	Set to **y** to append the job ID to the name of the output folder. The default is n. A job ID is helpful for making the correlation between a specific instance of a Report script and the corresponding report.
Select properties	Set miscellaneous report properties as desired. The default report name is Trunk Group By Hour.
Add time stamp to title?	Set to **y** to append a time stamp to the title of the report, making each title unique. The default is n. The time stamp is made up of the date and time the report was generated. Adding a time stamp is useful in order to run consecutive iterations of the same report without overwriting previous output.
Event Notification	
Raise event if report succeeds?	Set to **y** to raise an event when the report is successfully generated. The default is y.
Event severity when report succeeds	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report is successful. The default is 35.

Parameter	How to Set It
Event severity when report has no data	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report contains no data. The default is 25.
Event severity when report fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report fails. The default is 5.

17.31 Report_UnusedPhones

Use this Knowledge Script to create a list of unused phones. This script bases the report on the list of phones configured on Cisco Unified Communications Manager or Unified Communications Manager Express. It looks at the phones configured at the time of the most recent successful data collection, and then, using the criteria you set in the parameters, creates a list of phones that have been unused for *n* days.

When running this script, keep in mind how far back the data goes, including the initial data load. If you specify an initial data load of seven days, and then run this script, any phone whose last call was at least eight days ago will show up on the report as having no calls — in other words, as unused.

You can select Communications Managers or H.323 gateways as Data Sources for this report. Before using this report to identify unused Communications Manager Express phones (based on the H.323 gateways you select), run the CCME_GetConfig Knowledge Script, which provides meaningful data for all Communications Manager Express phones.

17.31.1 Resource Object

Report agent

17.31.2 Default Schedule

By default, this script runs once.

17.31.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Data Source	
Select data source	Select the data for your report by **View Name**, **Data Warehouse**, or **Data Source**. To work with Communications Manager Express phones, select **H.323 Gateways**.
Select time range	Select a **Specific** or **Sliding** date/time range from which the report should pull data. The default is Sliding.
Gateway name	Use this parameter *only* if you selected **H.323 Gateways** as a data source. Specify the name of the Communications Manager Express gateway for which you want to find unused phones. Alternatively, type a partial name and the * wildcard to indicate Communications Manager Express names that match a pattern. Leave this field blank to gather statistics for *all* Communications Manager Express gateways known by the data source.
Minimum days since last call	Specify the minimum unused days filter for calls selected by the script. Phones unused for less than the minimum will not be included in the report, even if all other criteria are satisfied. Type 0 to include all unused phones in the report.

Parameter	How to Set It
Minimum duration when looking for calls	Specify the minimum duration filter for calls selected by the script. Calls with a duration of less than the minimum will not be included in the report, even if all other criteria are satisfied. The default is 0 seconds.
Direction of calls	Specify the direction filter for calls selected by the script. You can choose to include calls that are **Outbound Only**, **Inbound Only**, or both **Inbound and Outbound**.
Report Settings	
Order rows by?	Select the criterion by which you want to sort the rows in the report: • **Most Recently Used**. In order by date from the most recently used phone to the least recently used phone. • **Least Recently Used**. In order by date from the least recently used phone to the most recently used phone. All phones used on any given day are sorted by directory number. For example, the report may show 10 phones used on April 4, 7 phones used on April 3, and 12 phones used on April 2. April 4th's 10 phones are sorted by directory number, as are the phones for April 3 and April 2.
Include parameter help card?	Set to **y** to include a table in the report that lists parameter settings for the report script. The default is y.
Select output folder	Set parameters for the output folder. The default folder name is UnusedPhones.
Add job ID to output folder name?	Set to **y** to append the job ID to the name of the output folder. The default is n. A job ID is helpful for making the correlation between a specific instance of a Report script and the corresponding report.
Select properties	Set miscellaneous report properties as desired. The default report name is Unused Phones.
Add time stamp to title?	Set to **y** to append a time stamp to the title of the report, making each title unique. The default is n. The time stamp is made up of the date and time the report was generated. Adding a time stamp is useful in order to run consecutive iterations of the same report without overwriting previous output.
Event Notification	
Raise event if report succeeds?	Set to **y** to raise an event when the report is successfully generated. The default is y.
Event severity when report succeeds	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report is successful. The default is 35.
Event severity when report has no data	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report contains no data. The default is 25.
Event severity when report fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report fails. The default is 5.

18 CallSetup Knowledge Scripts

AppManager for CallSetup/H.323 monitors the response time and availability of H.323 gateways and gatekeepers. Knowledge Scripts provide the ability to emulate H.323 client processes, including call registration and call setup using the H.323 protocol, ensuring that key H.323 devices are available and performing well on the network.

AppManager for CallSetup/SIP monitors the response time and availability of SIP. Knowledge Scripts provide the ability to emulate SIP client processes, including call registration and call setup using the SIP protocol, ensuring that key SIP devices are available and performing well on the network.

From the Knowledge Script view of Control Center, you can access more information about any NetIQ-supported Knowledge Script by selecting it and clicking **Help**. Or in the Operator Console, click any Knowledge Script in the Knowledge Script pane and press **F1**.

Knowledge Script	What It Does
H.323_CallSetup_Direct	Sets up a VoIP call directly between NetIQ endpoints over H.323 without the use of a gatekeeper or a gateway.
H.323_CallSetup_Gatekeeper	Sets up a VoIP call between NetIQ endpoints over H.323 using a gatekeeper.
H.323_CallSetup_Gateway	Sets up a VoIP call between NetIQ endpoints over H.323 using a gateway.
H.323_Listen	Causes the NetIQ endpoint to begin listening for H.323 communications on a given port.
H.323_Registration	Registers a NetIQ endpoint with a gatekeeper over H.323.
H.323_UpdateAlias	Updates the alias name of the H.323 resource in the repository.
Report_H.323Configuration	Displays the Call Setup H.323 configuration for the selected computers.
Report_H.323ResponseAvailMatrix	Displays the average response time and availability between talkers and listeners.
Report_H.323ResponseTimeDetail	Displays the average response time by minute.
Report_SIPConfiguration	Displays the Call Setup SIP configuration for the selected computers.
Report_SIPResponseAvailMatrix	Displays the average response time and availability between talkers and listeners.
Report_SIPResponseTimeDetail	Displays the average response time by minute.
SIP_CallSetup_Direct	Performs all of the steps associated with setting up a VoIP call using SIP directly between two endpoints.
SIP_CallSetup_Server	Performs all of the steps associated with setting up a VoIP call using a SIP server.

Knowledge Script	What It Does
SIP_Listen	Causes the NetIQ endpoint to begin listening for SIP communications on a given port.
SIP_Registration	Performs basic registration with the server and checks for response time, a valid response, and a successful return code.
SIP_UpdateAlias	Updates the alias name of the SIP resource in the repository.

18.1 H.323_CallSetup_Direct

Use this Knowledge Script to set up a VoIP call between NetIQ endpoints (one listener and one talker) over H.323 without the use of a gatekeeper or a gateway.

A direct call setup test tears down the call. The tear down is not included in the response time measurement. This script raises an event if response time exceeds the threshold that you set.

You can set up an H.323 call across a LAN to ensure that an H.323 device, such as NetMeeting, can make direct calls. This "loop back" monitoring job helps you verify proper installation and configuration of H.323 agent devices. In addition, you can determine the response time, which indicates LAN performance, for H.323 call setup between client devices.

18.1.1 Prerequisite

Run the H.323_Listen script without specifying gatekeeper information on the Values tab. You cannot initiate a CallSetup Knowledge Script job unless you first run the Listen job.

18.1.2 Resource Object

H.323 object

18.1.3 Default Schedule

By default, this script runs every 15 minutes.

18.1.4 Setting Parameter Values

Set the following parameters as necessary:

Parameter	How to Set It
Collect data?	Select **y** to collect data about response time for reports and graphs. The default is y.
Select listener(s)	Select the names of the computers that you want to act as listeners.
Threshold - Maximum response time	Specify the maximum amount of response time that can occur before an event is raised. The default is 500 milliseconds.
Event severity when response time exceeds the threshold	Set the event severity level, from 1 to 40, to reflect the importance of an event in which response time exceeds the threshold. The default is 15.
Event severity when call setup fails	Set the event severity level, from 1 to 40, to reflect the importance of an event in which the call setup test fails. The default is 5.
Listening port number	Enter the port number of the listening endpoint. This port number must match that of the listening port you specified in the H.323_Listen script. The default port number is 1720.
Use H.245 tunneling?	Select **y** to enable H.245 message encapsulation. The default is n.

18.2 H.323_CallSetup_Gatekeeper

Use this Knowledge Script to set up a VoIP call between NetIQ endpoints (one listener and one talker) over H.323 using a gatekeeper. A gatekeeper call is one in which the gatekeeper confirms the availability of the listener before allowing the talker to complete a call.

A gatekeeper call setup test tears down the call. The tear down is not included in the response time measurement. This script raises an event if response time exceeds the threshold that you set.

You can set up an H.323 call through a router gatekeeper to determine the response time, which indicates performance, for H.323 call setup across a WAN or to the PSTN (Public Switched Telephone Network).

TIP: Run the H.323_Registration script on the agent computer to monitor the gatekeeper's availability by registering and deregistering the agent computer with the gatekeeper.

18.2.1 Prerequisite

Run the H.323_Listen script and specify *all* of the gatekeeper parameters on the Values tab. The Listen script prepares the listener endpoint for listening. You cannot initiate a CallSetupKnowledge Script job unless you first run the Listen job.

18.2.2 Resource Object

H. 323 object

18.2.3 Default Schedule

By default, this script runs every 15 minutes.

18.2.4 Setting Parameter Values

Set the following parameters as necessary:

Parameter	How To Set It
Collect data?	Select **y** to collect data about response time for reports and graphs. The default is y.
Select listener(s)	Select the names of the computers that you want to act as listeners.
Threshold - Maximum response time	Specify the maximum amount of response time that can occur before an event is raised. The default is 500 milliseconds.
Event severity when response time exceeds the threshold	Set the event severity level, from 1 to 40, to reflect the importance of an event in which response time exceeds the threshold. The default is 15.
Event severity when call setup fails	Set the event severity level, from 1 to 40, to reflect the importance of an event in which the call setup test fails. The default is 5.
Name or IP address of gatekeeper	Enter the name or IP address of the gatekeeper. If you enter an incorrect IP address or leave the field blank, then this job will fail.

Parameter	How To Set It
Port to communicate with gatekeeper	Enter the port on the gatekeeper with which the signaling (talker) and listening ports will communicate in order to communicate with the gatekeeper. If you entered a name or IP address in *Name or IP address of gatekeeper*, then you *must* provide the port number. If you enter an incorrect port number or leave the field blank, then this job will fail. The default port number is 1719.
Password for use of gatekeeper	Enter the password, if any, associated with the gatekeeper. If you entered a name or IP address in *Name or IP address of gatekeeper*, then you *must* provide the applicable password. If you enter an incorrect password or leave the field blank, then this job will fail.
Use H.245 tunneling?	Select **y** to enable H.245 message encapsulation. The default is n.

18.3 H.323_CallSetup_Gateway

Use this Knowledge Script to set up a VoIP call between NetIQ endpoints (one listener and one talker) over H.323 using a gateway. A gateway call is one in which the talker funnels a call through a gateway, which determines the route of the call and availability of the listener. The gateway sends the call on to the listener.

A gateway call setup test tears down the call. The tear down is not included in the response time measurement.This script raises an event when response time exceeds the threshold that you set.

Some gateways may not be able to handle call setup tests for multiple calls or multiple listeners. For example, your test may fail if you attempt to set up a test with two listeners (from talker A to listeners B and C). In this case, run two separate call setup tests for the two calls: one from talker A to listener B, and another from talker A to listener C.

You can set up an H.323 call through a router gateway to determine the response time, which indicates performance, for H.323 call setup across a WAN or to the PSTN (Public Switched Telephone Network).

You can set up an H.323 call through Cisco Unified Communications Manager to ensure that Cisco soft phones can make calls. This "loop back" monitoring job helps you determine the response time, which indicates performance, for H.323 call setup through Communications Manager.

NOTE:

- Cisco Unified Communications Manager provides H.323 gateway services for soft phones because the phones use H.323, not SCCP, for call setup. You must manually configure all soft phones on a Communications Manager.
- If the name of the agent phone in AppManager is not the same as the "Device Name" in Communications Manager, run H.323_UpdateAlias. In the *New alias name* parameter, enter the same description that is used for the Communications Manager phone configuration "Device Name."
- Because Communications Manager is not a gatekeeper for H.323 devices, do not run H.323_CallSetup_Gatekeeper or H.323_Registration against a Communications Manager server.

18.3.1 Prerequisites

- Configure the gateway to associate the hostname of the endpoint computer with an H.323 alias, an arbitrary value that you determine.
- Run the H.323_UpdateAlias script to pull the configured alias information into AppManager.
- Run the H.323_Listen script without specifying any gatekeeper information on the Values tab. The Listen script prepares the listener endpoint for listening. You cannot initiate a CallSetup Knowledge Script job unless you first run a Listen job.

18.3.2 Resource Object

H. 323 object

18.3.3 Default Schedule

By default, this script runs every 15 minutes.

18.3.4 Setting Parameter Values

Set the following parameters as necessary:

Parameter	How To Set It
Collect data?	Select **y** to collect data about response time for reports and graphs. The default is y.
Select listener(s)	Select the names of the computers that you want to act as listeners. **NOTE:** Some gateways may not be able to handle call setup tests for multiple listeners. For example, your test may fail if you select two computers for this parameter. In this case, simply run this script twice — once for the first computer and then again for the second.
Threshold - Maximum response time	Specify the maximum amount of response time that can occur before an event is raised. The default is 500 milliseconds.
Event severity when response time exceeds the threshold	Set the event severity level, from 1 to 40, to reflect the importance of an event in which response time exceeds the threshold. The default is 15.
Event severity when call setup fails	Set the event severity level, from 1 to 40, to reflect the importance of an event in which the call setup test fails. The default is 5.
Name or IP address of gateway	Enter the name or IP address of the gatekeeper. If you enter an incorrect IP address or leave the field blank, then this job will fail.
Port to communicate with gateway	Enter the port on the gatekeeper with which the signaling (talker) and listening ports will communicate in order to communicate with the gatekeeper. If you enter an incorrect port number or leave the field blank, then this job will fail. The default port number is 1720.
Use H.245 tunneling?	Select **y** to enable H.245 message encapsulation. The default is n.

18.4 H.323_Listen

Use this Knowledge Script to cause the NetIQ endpoint to begin listening for H.323 communications on a given port. This script restarts the listening process on any agent computer whose endpoint goes down for any reason. It does not check against running multiple listening jobs on the same computer for the same alias and port — that is the job of the managed object.

The listening test will perform registration if the gatekeeper is specified in the script parameters. It is not necessary to perform both the registration test and the listening test. However, you must run the listen test before running any of the call setup tests.

18.4.1 Resource Object

H.323 object

18.4.2 Default Schedule

By default, this script runs on an asynchronous schedule.

18.4.3 Setting Parameter Values

Set the following parameters as necessary:

Parameter	How To Set It
Event severity when listening job fails	Set the event severity level, from 1 to 40, to reflect the importance of an event in which the listening job fails. The default is 5.
Listening port number	Enter the number of the listening port. The default is 1720.
Name of gatekeeper	Enter the IP address of the gatekeeper.
Port to communicate with gatekeeper	Enter the port on the gatekeeper with which the signaling port, or talker, will communicate in order to register with the gatekeeper. The default is 1719.
Password for use of gatekeeper	Enter the password, if any, associated with the gatekeeper.

18.5 H.323_Registration

Use this Knowledge Script to register a NetIQ endpoint computer (also called the signaling port or the talker) with a gatekeeper over H.323. Registration verifies the availability of the gatekeeper and allows a gatekeeper to map dialed numbers to an IP addressing structure.

You do not need to run this script before running the H.323_Listen script.The Listen script automatically performs registration if a gatekeeper is present.

The registration test returns one measurement: total response time for registering with a gatekeeper.

TIP: To monitor gatekeeper availability, run this script on the agent computer to register and deregister the agent computer with the gatekeeper.

18.5.1 Resource Object

H323Agent

18.5.2 Default Schedule

By default, this script runs every 15 minutes.

18.5.3 Setting Parameter Values

Set the following parameters as necessary:

Parameter	How To Set It
Collect data?	Select **y** to collect data for reports and graphs. The default is y.
Event severity when registration fails	Set the event severity level, from 1 to 40, to reflect the importance of an event in which registration fails. The default is 5.
Name or IP address of gatekeeper	Enter the name or IP address of the gatekeeper.
Port to communicate with gatekeeper	Enter the port on the gatekeeper with which the signaling port, or talker, will communicate in order to register with the gatekeeper. The default is 1719.
Password for use of gatekeeper	Enter the password, if any, associated with the gatekeeper.

18.6 H.323_UpdateAlias

Use this Knowledge Script to update the alias name of the H.323 resource in the repository. The alias name is the arbitrary name that you assigned the H.323 resource (the computer with the endpoint installed) when you configured it. By assigning an alias to the endpoint computer and then running H.323_UpdateAlias, you can pull all of the configured information into AppManager.

The new alias name is used when you stop and restart existing jobs or when you create new jobs. If you rerun the Discovery_VoIPQuality_CallSetup_H.323 Knowledge Script, the alias name is reset to the default name.

AppManager uses `<devicename>.netiq` as the default alias for H.323 devices. If a router gateway requires an access list, consider changing the alias to an IP address or to a fully qualified hostname so that the router can locate the AppManager managed object.

18.6.1 Resource Object

H.323 object

Run this script on only one resource at a time.

18.6.2 Default Schedule

By default, this script runs once.

18.6.3 Setting Parameter Values

Set the following parameters as necessary:

Parameter	How To Set It
New alias name	Enter a new alias name for the H.323 resource.
Event severity when update fails	Set the event severity level, from 1 to 40, to reflect the importance of an event in which the update fails. The default is 5.

18.7 Report_H.323Configuration

Use this Knowledge Script to summarize Call Setup H.323 configuration information for the selected computers.

18.7.1 Resource Object

Report agent

18.7.2 Default Schedule

By default, this script runs once.

18.7.3 Setting Parameter Values

Set the following parameters as necessary:

Parameter	How To Set It
Data Source	
Select computer(s)	Select the computers to include in the report. You can select computers by category: View, Server Group, or Computer. The default is View.
Report Settings	
Include parameter card?	Select **y** to include a table in the report that lists parameter settings for the report script. The default is y.
Select output folder	Select the name and location of the folder in which the report will be output. The default folder name is H323Config.
Add job ID to output folder name?	Select **y** to append the job ID to the name of the output folder. The default is n. A job ID helps you correlate a specific instance of a Report script with the corresponding report.
Select properties	Select report properties in the Report Properties dialog box. The default report name is Call Setup H.323 Configuration Report.
Add time stamp to title?	Select **y** to append a time stamp to the title of the report, making each title unique. The default is n. The time stamp consists of the date and time the report was generated. A time stamp lets you run consecutive iterations of the same report without overwriting previous output.
Event Notification	
Raise event if report succeeds?	Select **y** to raise an event when the report is successfully generated. The default is y.
Event severity when report succeeds	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report is generated successfully. The default is 35.

Parameter	How To Set It
Event severity when report has no data	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report contains no data. The default is 25.
Event severity when report fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report fails. The default is 5.

18.8 Report_H.323ResponseAvailMatrix

Use this Knowledge Script to summarize the average H.323 response time and availability between a talker and a listener within a time frame that you select.

18.8.1 Resource Object

Report agent

18.8.2 Default Schedule

By default, this script runs once.

18.8.3 Setting Parameter Values

Set the following parameters as necessary:

Parameter	How To Set It
Data Source	
Select Knowledge Script(s)	Select the Knowledge Scripts to include in the report.
Select computer(s)	Select which computers to include in the report. You can select computers by category: View, Server Group, or Computer. The default is View.
Select time range	Select a **Specific** or **Sliding** date/time range from which the report should pull data. The default is Sliding
Report Settings	
Decimal accuracy for % values	Specify the number of decimal places that you want to see in the values generated by this report. The default is 3.
Include parameter card?	Select **y** to include a table in the report that lists parameter settings for the report script. The default is y.
Select output folder	Select the name and location of the folder in which the report will be output. The default folder name is H323RespAvailMatrix.
Add job ID to output folder name?	Select **y** to append the job ID to the name of the output folder. The default is n. A job ID lets you correlate a specific instance of a Report script with the corresponding report.
Select properties	Set the report properties as desired. The default report name is Call Setup H.323 Response Time Availability.
Add time stamp to title?	Select **y** to append a time stamp to the title of the report, making each title unique. The default is n. The time stamp consists of the date and time the report was generated. A time stamp lets you run consecutive iterations of the same report without overwriting previous output.

Parameter	How To Set It
Event Notification	
Raise event if report succeeds?	Select **y** to raise an event when the report is successfully generated. The default is y.
Event severity when report succeeds	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report is generated successfully. The default is 35.
Event severity when report has no data	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report contains no data. The default is 25.
Event severity when report fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report fails. The default is 5.

18.9 Report_H.323ResponseTimeDetail

Use this Knowledge Script to summarize the average H.323 response time by minute within a time range that you select.

18.9.1 Resource Object

Report agent

18.9.2 Default Schedule

By default, this script runs once.

18.9.3 Setting Parameter Values

Set the following parameters as necessary:

Parameter	How To Set It
Data Source	
Select Knowledge Script(s)	Select the Knowledge Scripts to include in the report.
Select computer(s)	Select which computers to include in the report. You can select computers by category: View, Server Group, or Computer. The default is View.
Select time range	Select a **Specific** or **Sliding** date/time range from which the report should pull data. The default is Sliding.
Aggregate by n minute(s)	Enter the number of minutes in which time data will be grouped. The default is 15 minutes.
Report Settings	
Include parameter card?	Select **y** to include a table in the report that lists parameter settings for the report script. The default is y.
Include charts?	Select **y** to include a chart in the report. The default is y.
Include table?	Select **y** to include a table of information in the report. The default is y.
Select output folder	Select the name and location of the folder in which the report will be output. The default folder name is H323RespTimeDetail.
Add job ID to output folder name?	Select **y** to append the job ID to the name of the output folder. The default is n. A job ID helps you correlate a specific instance of a Report script with the corresponding report.
Select properties	Set the report properties as desired. The default report name is Call Setup H.323 Response Time Detail.
Add time stamp to title?	Select **y** to append a time stamp to the title of the report, making each title unique. The default is n. The time stamp consists of the date and time the report was generated. A time stamp lets you run consecutive iterations of the same report without overwriting previous output.

Parameter	How To Set It
Event Notification	
Raise event if report succeeds?	Select **y** to raise an event when the report is successfully generated. The default is y.
Event severity when report succeeds	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report is generated successfully. The default is 35.
Event severity when report has no data	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report contains no data. The default is 25.
Event severity when report fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report fails. The default is 5.

18.10 Report_SIPConfiguration

Use this Knowledge Script to summarize SIP call setup configuration information for the selected computers.

18.10.1 Resource Object

Report agent

18.10.2 Default Schedule

By default, this script runs once.

18.10.3 Setting Parameter Values

Set the following parameters as necessary:

Parameter	How To Set It
Data Source	
Select computer(s)	Select the computers to include in the report. You can select computers by category: View, Server Group, or Computer. The default is View.
Report Settings	
Include parameter card?	Select **y** to include a table in the report that lists parameter settings for the report script. The default is y.
Select output folder	Select the name and location of the folder in which the report will be output. The default folder name is SIPConfig.
Add job ID to output folder name?	Select **y** to append the job ID to the name of the output folder. The default is n. A job ID lets you correlate a specific instance of a Report script with the corresponding report.
Select properties	Set the properties parameters as desired. The default report name is Call Setup SIP Configuration Report.
Add time stamp to title?	Select **y** to append a time stamp to the title of the report, making each title unique. The default is n. The time stamp consists of the date and time the report was generated. A time stamp lets you run consecutive iterations of the same report without overwriting previous output.
Event Notification	
Raise event if report succeeds?	Select **y** to raise an event when the report is successfully generated. The default is y.
Event severity when report succeeds	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report is generated successfully. The default is 35.

Parameter	How To Set It
Event severity when report has no data	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report contains no data. The default is 25.
Event severity when report fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report fails. The default is 5.

18.11 Report_SIPResponseAvailMatrix

Use this Knowledge Script to summarize the average SIP response time and availability between a talker and a listener within a time frame that you select.

18.11.1 Resource Object

Report agent

18.11.2 Default Schedule

By default, this script runs once.

18.11.3 Setting Parameter Values

Set the following parameters as necessary:

Parameter	How To Set It
Data Source	
Select Knowledge Script(s)	Select the Knowledge Scripts to include in the report.
Select computer(s)	Select which computers to include in the report. You can select computers by category: View, Server Group, or Computer. The default is View.
Select time range	Select a **Specific** or **Sliding** date/time range from which the report should pull data. The default is Sliding
Report Settings	
Decimal accuracy for % values	Enter the number of decimal places that you want to see in the values generated by this report. The default is 3.
Include parameter card?	Select **y** to include a table in the report that lists parameter settings for the report script. The default is y.
Select output folder	Select the name and location of the folder in which the report will be output. The default folder name is SIPRespAvailMatrix.
Add job ID to output folder name?	Select **y** to append the job ID to the name of the output folder. The default is n. A job ID helps you correlate a specific instance of a Report script with the corresponding report.
Select properties	Set the report properties as desired. The default report name is Call Setup SIP Response Time Availability.
Add time stamp to title?	Select **y** to append a time stamp to the title of the report, making each title unique. The default is n. The time stamp consists of the date and time the report was generated. A time stamp lets you run consecutive iterations of the same report without overwriting previous output.

Parameter	How To Set It
Event Notification	
Raise event if report succeeds?	Select **y** to raise an event when the report is successfully generated. The default is y.
Event severity when report succeeds	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report is generated successfully. The default is 35.
Event severity when report has no data	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report contains no data. The default is 25.
Event severity when report fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report fails. The default is 5.

18.12 Report_SIPResponseTimeDetail

Use this Knowledge Script to summarize the average SIP response time by minute within a time range that you select.

18.12.1 Resource Object

Report agent

18.12.2 Default Schedule

By default, this script runs once.

18.12.3 Setting Parameter Values

Set the following parameters as necessary:

Parameter	How To Set It
Data Source	
Select Knowledge Script(s)	Select the Knowledge Scripts to include in the report.
Select computer(s)	Select which computers to include in the report. You can select computers by category: View, Server Group, or Computer. The default is View.
Select time range	Select a **Specific** or **Sliding** date/time range from which the report should pull data. The default is Sliding.
Aggregate by n minute(s)	Enter the interval in minutes in which time data will be grouped. The default is 15 minutes.
Report Settings	
Include parameter card?	Select **y** to include a table in the report that lists parameter settings for the report script. The default is y.
Include charts?	Select **y** to include a chart in the report. The default is y.
Include table?	Select **y** to include a table of information in the report. The default is y.
Select chart style	Define the graphic properties for the charts in your report. The default style is Line.
Select output folder	Select the name and location of the folder in which the report will be output. The default folder name is SIPRespTimeDetail.
Add job ID to output folder name?	Select **y** to append the job ID to the name of the output folder. The default is n. A job ID lets you correlate a specific instance of a Report script with the corresponding report.
Select properties	Set the report properties as desired. The default report name is Call Setup SIP Response Time Detail.

Parameter	How To Set It
Add time stamp to title?	Select **y** to append a time stamp to the title of the report, making each title unique. The default is n. The time stamp consists of the date and time the report was generated. A time stamp lets you run consecutive iterations of the same report without overwriting previous output.
Event Notification	
Raise event if report succeeds?	Select **y** to raise an event when the report is successfully generated. The default is y.
Event severity when report succeeds	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report is generated successfully. The default is 35.
Event severity when report has no data	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report contains no data. The default is 25.
Event severity when report fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report fails. The default is 5.

18.13 SIP_CallSetup_Direct

Use this Knowledge Script to perform all of the steps associated with setting up a VoIP call using SIP directly between two endpoints: 1) send a SIP `INVITE` message to the listener endpoint, 2) encapsulate media information, including codec and RTP ports in the body of the `INVITE` message using SDP, and 3) process the server's response to determine whether the call was successfully initiated.

This script raises an event when response time exceeds the threshold that you set.

You can set up SIP call across a LAN to ensure that a SIP device can make direct calls. This "loop back" monitoring job list you verify proper installation and configuration of SIP agent devices. In addition, you can determine the response time, which indicates LAN performance, for SIP call setup between client devices.

18.13.1 Prerequisites

- Run SIP_Listen to verify that the endpoint is available and capable of receiving incoming calls.
- This script assumes that the SIP registrar has the same IP address as the proxy agent computer.

18.13.2 Resource Object

SIP object

18.13.3 Default Schedule

By default, this script runs every 15 minutes.

18.13.4 Setting Parameter Values

Set the following parameters as necessary:

Parameter	How To Set It
Collect data?	Select **y** to collect data for reports and graphs. The default is y.
Select listener(s)	Select the names of the computers that you want to act as listeners.
Threshold - Maximum response time	Specify the maximum amount of response time that can occur before an event is raised. The default is 800 milliseconds.
Event severity when response time exceeds the threshold	Set the severity level, from 1 to 41, to indicate the importance of an event in which response time exceeds the threshold. The default is 15.
Event severity when SIP call is unsuccessful	Set the severity level, from 1 to 41, to indicate the importance of an event in which the SIP call does not complete successfully. The default is 5.
Talker port number	Enter the port number of the talker computer. The default is 5060.
Listener port number	Enter the port number of the listener computer. The default is 5060.

18.14 SIP_CallSetup_Server

Use this Knowledge Script to perform all of the steps associated with setting up a VoIP call that is routed from one endoint to another through a SIP server.

- First, the script sends a SIP `INVITE` message to the listener endpoint via a SIP server.
- *If the SIP server is a proxy server*, then the script performs all signaling functions through the proxy.
- *If the SIP server is a redirect server*, then the script parses the new URL (in the Contact field) and contacts that server to actually set up the call.
- Next, the script encapsulates media information, including codec and RTP ports in the body of the `INVITE` message using SDP.
- Finally, the script processes the server's response to determine whether the call was successfully initiated.

This script raises an event when response time exceeds the threshold that you set.

18.14.1 Prerequisites

- Run SIP_Listen, which verifies that the endpoint is available and capable of receiving incoming calls.
- This script assumes that the SIP registrar has the same IP address as the proxy agent computer.

18.14.2 Resource Object

SIPAgent

18.14.3 Default Schedule

By default, this script runs every 15 minutes.

18.14.4 Setting Parameter Values

Set the following parameters as necessary:

Parameter	How To Set It
Collect data?	Select **y** to collect data about response time for reports and graphs. The default is y.
Select listener(s)	Select the names of the computers that you want to act as listeners.
Threshold - Maximum response time	Specify the maximum amount of response time that can occur before an event is raised. The default is 800 milliseconds.
Event severity when response time exceeds the threshold	Set the severity level, from 1 to 41, to indicate the importance of an event in which response time exceeds the threshold. The default is 15.

Parameter	How To Set It
Event severity when SIP call is unsuccessful	Set the severity level, from 1 to 41, to indicate the importance of an event in which the SIP call does not complete successfully. The default is 5.
Talker port number	Enter the port number of the talker computer. The default is 5060.
Listener port number	Enter the port number of the listener computer. The default is 5060.
Name or IP address of proxy	Enter the name or IP address of the proxy computer.
Proxy port number	Enter the port number of the proxy computer. The default is 5060.
Register talker with proxy?	Enter **y** to register the talker computer with the proxy computer. The default is n.

18.15 SIP_Listen

Use this Knowledge Script to start a new thread, open a specified port, listen for incoming SIP messages, and then automatically return a response that indicates success. If necessary, the test registers the SIP endpoint with a SIP server so that the SIP endpoint can receive incoming calls in a server-based environment. SIP_Listen continues to run asynchronously until the job is stopped. It polls the endpoint every 60 seconds and refreshes the registration, if necessary, and it issues a `stop listen` command when the job is stopped.

18.15.1 Prerequisite

This script assumes that the SIP registrar has the same IP address as the proxy agent computer.

18.15.2 Resource Object

SIPAgent

18.15.3 Default Schedule

By default, this script runs on an asynchronous schedule. Regardless of the schedule that you select, once you start the script, its job status appears as Running.

18.15.4 Setting Parameter Values

Set the following parameters as necessary:

Parameter	How To Set It
Event severity when registration fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which registration is unsuccessful. The default is 5.
Listener port number	Enter the port number of the listener computer. The default is 5060.
Name or IP address of proxy	Enter the name or IP address of the proxy computer.
Proxy port number	Enter the port number of the proxy computer. The default is 5060.

18.16 SIP_Registration

Use this Knowledge Script to perform basic registration with the server and checks for response time, a valid response, and a successful return code. Upon completion, this script immediately deregisters with the server by sending a `REGISTER` request with a TTL of **0**.

You do not need to run this script before running SIP_Listen. The Listen script automatically performs registration.

This script raises an event when response time exceeds the threshold that you set.

18.16.1 Prerequisite

This script assumes that the SIP registrar has the same IP address as the proxy agent computer.

18.16.2 Resource Object

SIP object

18.16.3 Default Schedule

By default, this script runs every 15 minutes.

18.16.4 Setting Parameter Values

Set the following parameters as necessary:

Parameter	How To Set It
Collect data?	Select **y** to collect data about response time for reports and graphs. The default is y.
Threshold - Maximum response time	Specify the maximum amount of response time that can occur before an event is raised. The default is 800 milliseconds.
Event severity when response time exceeds the threshold	Set the severity level, from 1 to 40, to indicate the importance of an event in which response time exceeds the threshold. The default is 15.
Event severity when registration fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which registration fails. The default is 5.
Registrant port number	Enter the port number of the computer that you want to register. The default is 5060.
Name or IP address of proxy	Enter the name or IP address of the proxy computer.
Proxy port number	Enter the port number of the proxy computer. The default is 5060.

18.17 SIP_UpdateAlias

Use this Knowledge Script to update the alias or DNS name of the SIP resource in the repository. You can drop this script on only one resource at a time. Once you update the alias/DNS name, the new name is used when you stop and restart existing jobs or when you create new jobs. If you rerun the Discovery_VoIPQuality_CallSetup_SIP script, the alias/DNS name is reset to the default name.

NOTE: The alias/DNS name is the arbitrary name you assigned the SIP resource (the computer with the endpoint installed) when you configured it. To pull all configured information into AppManager, assign an alias/DNS name to the endpoint computer and then run SIP_UpdateAlias.

18.17.1 Prerequisite

This script assumes that the SIP registrar has the same IP address as the proxy agent computer.

18.17.2 Resource Object

SIP object

18.17.3 Default Schedule

By default, this script runs once.

18.17.4 Setting Parameter Values

Set the following parameters as necessary:

Parameter	How To Set It
New alias name	Provide a new alias name for the SIP resource. You can enter an alias name in addition to a DNS name or instead of a DNS name.
New DNS name	Provide a new DNS name for the SIP resource. You can enter a DNS name in addition to an alias name or instead of an alias name.
Event severity when update fails	Set the event severity level, from 1 to 40, to reflect the importance of an event in which the alias update fails. The default is 5.

19 CiscoCallMgr Knowledge Scripts

Cisco CallManager software provides enterprise telephony features and functions for packet-based network devices, including IP phones, media processing devices, voice over IP (VoIP) gateways, and multimedia applications. It offers an API that allows for additional data, voice, and video services such as unified messaging and multimedia video conferencing.

AppManager Knowledge Scripts help you monitor and regulate services that are critical to Cisco CallManager performance. From the Knowledge Script view of Control Center, you can access more information about any NetIQ-supported Knowledge Script by selecting it and clicking **Help**. Or in the Operator Console, click any Knowledge Script in the Knowledge Script pane and press **F1**.

Knowledge Script	What It Does
AnalogOutboundBusy	Monitors the number of times during an interval that a call was attempted through an analog access when no ports were available.
AnalogPortsActive	Monitors active ports.
AnalogPortsOutOfService	Monitors out-of-service ports.
CallActivity	Monitors call activity on selected CallManagers.
CallFailures	Monitors Call Detail Records for calls that have an abnormal cause of termination.
CallQuality	Monitors the calls recorded in the Call Management Records for jitter, latency, lost data, and listening MOS.
CallsActive	Monitors active calls.
CallsAttemptedByPhone	Monitors calls attempted by an individual phone.
CallsInProgress	Monitors the number of calls in progress and the percentage of in-progress calls that are active.
CCM_CheckFirmware	Detects any device that is not using the default firmware load. Replaces the need to launch the Cisco CallManager Administration Web page in order to determine the same information.
CCM_CpuHigh	Monitors CPU usage for CallManager processes.
CCM_DeviceStatus	Monitors the status of up to 100 key phones within a cluster.
CCM_EventLog	Monitors event log entries from CallManager during the past *n* hours.
CCM_FXOPorts	Monitors active and in-service FXO ports for a CallManager.
CCM_FXSPorts	Monitors active and in-service FXS ports for a CallManager.
CCM_HealthCheck	Monitors the status of CallManager services.
CCM_HeartBeat	Monitors the CallManager heartbeat. A low heartbeat indicates the CallManager service was stopped and then restarted.

Knowledge Script	What It Does
CCM_MemByProcess	Monitors individual memory use for each specified process, and the total memory use for all specified processes.
CCM_MemoryHigh	Monitors memory usage and memory pool usage of specified CallManager processes.
CCM_MOHUnavailable	Monitors the number of times an attempt was made to allocate a Music On Hold resource when all MOH servers were active or when no MOH servers were registered.
CCM_PhoneCheck	Monitors your CallManager network for new and missing phones.
CCM_PhoneInventory	Takes an inventory of phones based on specified search criteria. You can choose to write the results to a file.
CCM_PRIChannels	Monitors active and in-service PRI channels for a CallManager.
CCM_Replication	Queries for failed actions in the history tables of the replication agents on the CallManager Publisher.
CCM_ResetDevice	Resets one or more devices in order for the devices to pick up new default firmware.
CCM_RestartService	Schedules a CallManager service to stop and then restart after a specified interval.
CCM_RoleStatus	Determines whether a CallManager's status is Primary or Backup. A Backup is defined as any CallManager with no registered phones (hardware or software).
CCM_SecureWebPageCheck	Monitors the ccmadmin and ccmuser Web pages for Cisco CallManager 4.1 and later.
CCM_SystemPerformance	Monitors call throttling, signals in queue, and severe and warning call-throttling states for a CallManager.
CCM_SystemUsage	Monitors average CPU and memory usage for all monitored CallManagers.
CCM_T1Channels	Monitors active and in-service T1-CAS channels for a CallManager.
CCM_WebPageCheck	Monitors up/down status and round-trip time for the ccmadmin and ccmuser Web pages. If you are monitoring CallManager 4.1 or later, use CCM_SecureWebPageCheck.
CDRQuery	Queries the CDR table on the CallManager Publisher.
CiscoBackupStatus	Monitors the status of the Cisco Backup Utility program (stiBack.exe) and the Cisco BARS program.
ConfBridgeActiveConf	Monitors active conferences for a Conference Bridge.
ConfBridgeActiveStreams	Monitors active streams for a Conference Bridge.
ConfBridgeAvailStreams	Monitors available streams for a Conference Bridge.
	Monitors completed conferences for a Conference Bridge.
ConfBridgeStreams	Monitors streams on completed conferences for a Conference Bridge.
CTI_Manager	Monitors CTI Manager connections, open devices, open lines, and active CallManager links.
DigitalOutboundBusy	Monitors the number of times during an interval that a call through a Digital Access was attempted when no ports were available.
DigitalPortsActive	Monitors active digital ports.

Knowledge Script	What It Does
DigitalPortsOutOfService	Monitors out-of-service digital ports.
H323CallActivity	Monitors call activity on an H.323 device.
H323CallsAttempted	Monitors attempted calls for an H.323 device.
H323CallsInProgress	Monitors in-progress calls for an H.323 device.
IIS_CpuHigh	Monitors CPU usage for IIS application processes.
IIS_HealthCheck	Monitors the queue length for blocked I/O requests and the up-and-down status of IIS services and Web sites.
IIS_KillTopCPUProcs	Monitors CPU usage of the dllhost and MTX processes.
IIS_MemoryHigh	Monitors memory usage and memory pool usage of specified IIS applications.
IIS_RestartServer	Restarts an IIS server.
IIS_ServiceUpTime	Monitors discovered Web sites and Web services uptime.
LineStatus	Monitors active calls for an individual line.
LocationBandwidth	Monitors the bandwidth statistics for a Location resource that has been defined in CallManager.
LocationOutOfBandwidth	Monitors the number of times calls through a Location failed due to lack of bandwidth.
LossOfHardwarePhones	Monitors registered hardware phones.
MGCP_FXO	Monitors call activity for MGCP FXO devices.
MGCP_FXS	Monitors call activity for MGCP FXS devices.
MGCP_Gateway_CCM30	Monitors station ports and voice channels for CallManager 3.0 MGCP gateway devices.
MGCP_Gateway_CCM31	Monitors station ports and voice channels for CallManager 3.1 (and higher) MGCP gateway devices.
MGCP_GatewayCheck	Monitors for new or missing MGCP gateways.
MGCP_PRI	Monitors call activity and data link availability for MGCP PRI devices.
MGCP_PRI_Channels	Monitors active and out-of-service channels for MGCP PRI devices.
MGCP_T1CAS	Monitors call activity and data link availability for MGCP T1-CAS devices.
MGCP_T1CAS_Channels	Monitors active and out-of-service channels for MGCP T1-CAS devices .
MLA_Logins	Scans the CallManager MLA log file for successful and failed logins during a specified interval.
MOHDevice	Monitors active and available resources for Music On Hold devices.
MOHServer	Monitors active and available streams for Music On Hold servers.
MOHServer_LostConnections	Monitors lost connections for Music On Hold servers.
MTP_Device	Monitors active and available resources for a Media Termination Point device.
MTPActiveConnections	Monitors active connections for a Media Termination Point.
MTPActiveStreams	Monitors active streams for a Media Termination Point.

Knowledge Script	What It Does
MTPAvailableStreams	Monitors available streams for a Media Termination Point.
MTPCompletedConnections	Monitors completed connections for a Media Termination Point.
MTPCompletedStreams	Monitors streams on completed connections for a Media Termination Point.
MTPsActive	Monitors active Media Termination Points.
MTPsAvailable	Monitors available Media Termination Points.
MTPsUnavailable	Monitors the number of times during an interval a Media Termination Point allocation was requested when none was available.
MulticastConfActive	Monitors active Multicast conferences.
MulticastConfAvailable	Monitors the number of new Multicast conferences that can be started.
MulticastConfCompleted	Monitors completed Multicast conferences.
MulticastConfPhones	Monitors active Multicast participants.
MulticastConfUnavailable	Monitors the number of times during an interval a Multicast conference was requested when none was available.
QRTEvent	Monitors the log files of the Quality Reporting Tool and starts a diagnostic action if a QRT request has been logged.
RegAnalogAccesses	Monitors registered analog accesses.
RegCtiPorts	Monitors CTI ports registered to the local CallManager.
RegDigitalAccesses	Monitors registered digital accesses.
RegHardwarePhones	Monitors registered hardware phones.
RegMGCPGateways	Monitors registered MGCP gateways.
RegOtherDevices	Monitors registered station devices using the SCCP protocol that are not hardware phones.
Report_CallActivity	Summarizes data relating to attempted and completed calls.
Report_CallQualityDailyAvg	Summarizes key call quality data: jitter, latency, and lost data.
Report_CallsByHour	Displays the number of active calls for all selected CallManagers.
Report_ClusterAvgValueByHr	Displays the average values by hour of the data stream(s) for all selected CallManager clusters.
Report_ClusterAvgValueByMin	Displays the average values by minute of the data stream(s) for the selected CallManager cluster.
Report_ClusterGenCounter	For a selected CallManager cluster, displays the average, maximum, and minimum values of each data stream, and the actual data values of each data stream over time.
Report_ClusterSystemUsage	For a selected CallManager cluster, displays the average CPU and memory usage per CallManager.
Report_MGCPChannelUsage	Displays the number of total active and out-of-service voice channels for a particular MGCP PRI Group.
Report_MGCPDeviceUtil	Displays outbound busy attempts and completed calls for a particular MGCP device.
Report_MGCPGatewayUsage	Displays the number of active MGCP PRI Voice Channels for a particular gateway.

Knowledge Script	What It Does
Report_ServicesAvailability	Summarizes the availability of the services most relevant to the selected CallManagers.
Report_SystemUsage	Displays the average CPU and memory usage for the selected CallManagers.
SQL_Accessibility	Monitors SQL Server and database accessibility.
SQL_BlockedProcesses	Monitors SQL processes that have been blocked for more than the specified period of time.
SQL_CPUUtil	Monitors CPU resources used by sqlservr and sqlagent processes.
SQL_DataGrowthRate	Monitors data growth and shrink rates for all SQL Server databases.
SQL_DataSpace	Monitors available data space and used data space in a SQL Server 7.0 database.
SQL_DBGrowthRate	Monitors database growth and shrink rates.
SQL_DbOption	Checks the database option.
SQL_DBSpace	Monitors available database space and used database space in a SQL Server 7.0 database.
SQL_Errorlog	Monitors the SQL Server error log.
SQL_LogGrowthRate	Monitors log growth and shrink rates for all SQL Server databases.
SQL_LogSpace	Monitors available log space and log data space in a SQL Server 7.0 database.
SQL_MemUtil	Monitors the percentage of memory used by `sqlservr` and `sqlagent` processes.
SQL_NearFileMaxSize	Monitors the size of all SQL Server database files.
SQL_NearMaxConnect	Monitors the percentage of used user connections.
SQL_NearMaxLocks	Monitors the lock usage of SQL Server.
SQL_NetError	Monitors SQL Server network packet errors.
SQL_RepTransactions	Monitors transactions in the transaction log of the publication database that are marked for replication but have not been replicated.
SQL_RepTranSec	Monitors transactions being replicated per second.
SQL_RestartServer	Restarts a down SQL Server.
SQL_ServerDown	Monitors the up-and-down status of SQL Server.
SQL_ServerThroughput	Monitors the throughput of SQL Server by measuring the number of T-SQL batch requests executed per second and the number of physical page reads per second.
SQL_TopIOUsers	Monitors I/O read-and-write operations used by SQL Server users and their connections.
SQL_TopLockUsers	Monitors locks held by all SQL Server users and their connections.
SQL_TopMemoryUsers	Monitors the memory that can be allocated to all SQL Server users and their connections in 2-KB pages.
SQL_UserConnections	Monitors SQL Server user connections.
StreamAppIOCTLErr	Monitors the number of times in an interval an IOCTL error was detected.

Knowledge Script	What It Does
StreamAppMissDDErr	Monitors the number of times in an interval a missing device driver error was detected.
TftpChangeNotify	Monitors handled TFTP change notifications.
TftpErrors	Monitors TFTP-related errors.
TftpHeartBeat	Monitors the Cisco TFTP heartbeat.
TftpRequests	Monitors handled TFTP requests.
TftpSegmentPctLost	Monitors lost TFTP segments.
TftpSegmentsSent	Monitors sent TFTP segments.
TraceArchive	Archives CallManager trace files to prevent losing files when tracing wraps.
TraceEvent	Scans CallManager trace files for entries that match a text string you specify.
Transcoder_Device	Monitors active and available resources for an individual transcoder device.
TranscoderResources	Monitors transcoder resources between the G.711, G.723, and G.729 codecs.
TranscoderUnavailable	Monitors the number of times during a specified period a transcoder resource was requested when none was available.
UnicastConfActive	Monitors active Unicast conferences.
UnicastConfAvailable	Monitors the number of new Unicast conferences that can be started.
UnicastConfBridge_Device	Monitors active and available resources for an individual software or hardware conference bridge device.
UnicastConfComplete	Monitors completed Unicast conferences.
UnicastConfParticipants	Monitors active Unicast participants.
UnicastConfUnavailable	Monitors the number of times in an interval a Unicast conference was requested when none was available.
VerifyPasswords	Verifies the sa, Administrator, and Directory Manager passwords on a CallManager computer.
Recommended Knowledge Script Groups	Run all recommended Knowledge Scripts at one time.

19.1 AnalogOutboundBusy

Use this Knowledge Script to monitor the number of times a call was attempted through an analog access when no ports were available. This script raises an event if the number of outbound busy attempts exceeds the threshold. In addition, this script generates a data stream for outbound busy attempts.

19.1.1 Resource Object

CCM Analog Access object

19.1.2 Default Schedule

By default, this script runs every 30 minutes.

19.1.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if threshold is exceeded?	Set to **y** to raise an event if the number of outbound busy attempts exceeds the threshold. The default is y.
Collect data?	Set to **y** to collect data about outbound busy attempts for reports and graphs. The default is n.
Threshold - Maximum outbound busy attempts	Specify the maximum number of outbound busy attempts can occur before an event is raised. The default is 100 calls.
Event severity when threshold is exceeded	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of outbound busy attempts exceeds the threshold. The default is 25.

19.2 AnalogPortsActive

Use this Knowledge Script to monitor the number of active ports. This script raises an event if the number of active ports exceeds the threshold. In addition, this script generates a data stream for the number of active ports.

19.2.1 Resource Object

CCM Analog Access object

19.2.2 Default Schedule

By default, this script runs every 30 minutes.

19.2.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if threshold is exceeded?	Set to **y** to raise an event if the number of active ports exceeds the threshold. The default is y.
Collect data?	Set to **y** to collect data about active ports for reports and graphs. The default is n.
Threshold - Maximum active ports	Specify the maximum number of ports that can be active before an event is raised. The default is 20 ports.
Event severity when threshold is exceeded	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of active ports exceeds the threshold. The default is 25.

19.3 AnalogPortsOutOfService

Use this Knowledge Script to monitor the number of ports that are out of service. This script raises an event if the number of out-of-service ports exceeds the threshold. In addition, this script generates a data stream for out-of-service ports.

19.3.1 Resource Object

CCM Analog Access object

19.3.2 Default Schedule

By default, this script runs every 30 minutes.

19.3.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if threshold is exceeded?	Set to **y** to raise an event if the number of out-of-service ports exceeds the threshold. The default is y.
Collect data?	Set to **y** to collect data about out-of-service ports for reports and graphs. The default is n.
Threshold - Maximum out-of-service ports	Specify the maximum number of ports that can be out of service before an event is raised. The default is 2 ports.
Event severity when threshold is exceeded	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of out-of-service ports exceeds the threshold. The default is 15.

19.4 CallActivity

Use this Knowledge Script to monitor call activity (attempted, completed, and incomplete) during a specified time range.

This script collects the data used by the Report_CallActivity Knowledge Script.

This script is a member of a Recommended Knowledge Script Group. For more information, see "Recommended Knowledge Script Groups" on page 1057.

19.4.1 Resource Object

CCM Call Processor

19.4.2 Default Schedule

By default, this script runs once each day.

19.4.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Collect data?	Set to **y** to collect data about call activity for reports and graphs. The default is y.
Monitor completed calls?	Set to **y** to monitor completed calls. The default is y.
Threshold - Maximum completed calls	Specify the maximum number of calls that can be completed before an event is raised. The default is 500 calls.
Event severity when completed calls exceed the threshold	Set the severity level, from 1 to 40, to indicate the importance of an event in which completed calls exceed the threshold. Enter **0** if you do not want to raise an event. The default is 25.
Monitor attempted calls?	Set to **y** to monitor attempted calls, such as calls that received a busy signal or in instances when users leave the handset off the phone. The default is y.
Threshold - Maximum attempted calls	Specify the maximum number of calls that can be attempted before an event is raised. The default is 500 calls.
Event severity when attempted calls exceed the threshold	Set the severity level, from 1 to 40, to indicate the importance of an event in which attempted calls exceed the threshold. Enter **0** if you do not want to raise an event. The default is 25.
Monitor incomplete calls?	Set to **y** to monitor incomplete calls, such as calls that were attempted but did not complete or are not currently in progress. The default is y.
Threshold - Maximum incomplete calls	Specify the maximum percentage of incomplete calls can occur before an event is raised. The default is 75%.
Event severity when incomplete calls exceed the threshold	Set the severity level, from 1 to 40, to indicate the importance of an event in which the percentage of incomplete calls exceeds the threshold. Enter **0** if you do not want to raise an event. The default is 25.

19.5 CallFailures

Use this Knowledge Script to monitor the Call Detail Records (CDR) in the CallManager Publisher database for calls that ended with an abnormal cause code.

If a Subscriber loses its connection to a Publisher, it will store its CDR data locally until the connection is restored. If the connection is not restored within the collection interval, this script may not monitor some calls.

NOTE: CallManager does not collect CDR records by default. You must enable the collection of CDRs for each CallManager is a cluster. From the Cisco CallManager Administration Web page, navigate to **Service > Service Parameters > CallManager**. Set the **CdrEnabled** parameter to **T**.

19.5.1 Resource Object

CCM Publisher

19.5.2 Default Schedule

By default, this script runs every five minutes.

19.5.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if failed calls exceed the threshold?	Set to **y** to raise an event if the number of failed calls exceeds the threshold. The default is y.
Collect data?	Set to **y** to collect data for graphs and reports. The default is n. This parameter collects the total number of failed calls found during the time period you specify in the *Start time*, *Start date*, *Stop time*, and *Stop date* parameters. **NOTE:** Some third-party billing applications remove CDR records from the CallManager database. If records are removed before the CallFailures script has a chance to run, the script will not collect any data.
CallManager database username	Provide the user login account required to access the CallManager SQL Server database. Leave this field blank to accept the default Cisco login account: `CiscoCCMCDR`. If you changed the default password for `CiscoCCMCDR`, or want to use a different login account, configure the login and password using AppManager Security Manager before running this script. On the SQL tab of Security Manager, provide the IP address or hostname of the CallManager **SQL Server** computer, as well as the **SQL Login Name** and **SQL Login password**.

Parameter	How to Set It
Use Windows authentication?	Set to **y** to use Windows authentication to access the Publisher database. If you enable this parameter, the SQL user name is ignored. The `NetIQmc` service must be running with the proper authentication to access the database. The default is Yes.
Threshold - Maximum failed calls	Specify the maximum number of calls that can fail before an event is raised. The default is 0 calls. **NOTE:** You can trigger NetIQ Vivinet Diagnostics to diagnose the problem indicated by an event in which this threshold is exceeded. For more information, see "Diagnosing VoIP Quality" on page 835.
Include call details?	Set to **y** to include call details in the event message. The default is y. If set to y, the event message includes details for up to 50 calls. The call details can include any or all of the following: • Originator termination cause • Destination termination cause • Originating Party Device Name (if running on CallManager 3.1 or later) • Originating Party Directory Number • Originating Party Partition • Originating Party CallManager Node ID • Originating Party IP address • Originating Party codec • Destination Party Device Name (if running on CallManager 3.1 or later) • Destination Party Directory Number • Destination Party Partition • Destination Party CallManager Node ID • Destination Party IP address • Destination Party codec • Time the call was connected • Time the call was disconnected • Call duration
Directory number to filter by	Provide a directory number by which to filter the calls that get monitored. The default is to monitor all calls. You can specify a group of directory numbers by using the % wildcard. For example, to monitor all the directory numbers that begin with 31, enter 31%. **NOTE:** This parameter returns results only if the directory number you enter is the originator's number. No results are returned if you enter the destination number.
Exclude these failure codes	Provide a comma-separated list of termination codes that are not to be considered failures. For more information, see "Termination Codes" on page 836. **NOTE:** Codes 0, 16, 31, and 127 are automatically excluded. They are normal termination codes. However, these codes may appear in events if the other side of the call has a failure code that has not been excluded.

Parameter	How to Set It
Minimum call duration	Specify the minimum number of seconds for which a call must be connected before the script checks whether the call has failed and includes it in the query. The default is 0 seconds.
Start date	Specify the date on which you want to start the query. This parameter is valid only when you select **Run Once** on the Schedule tab.
Start time	Specify the time at which you want to start the query. This parameter is valid only when you select **Run Once** on the Schedule tab.
Stop date	Specify the date on which you want to stop the query. This parameter is valid only when you select **Run Once** on the Schedule tab.
Stop time	Specify the time at which you want to stop the query. This parameter is valid only when you select **Run Once** on the Schedule tab.
Query timeout	Specify the maximum number of seconds it can take a query to run. The default is 10 seconds. **NOTE:** The script runs three queries in order to get data for each interval.
Monitoring offset	Because CallManager can have a delay when writing records to the database, a query may not return any call failures if the script is monitoring only the past few seconds. Use this parameter to have the script offset the monitoring period in order to capture those failures that occurred earlier. The default is 45 seconds. For example, if the delay for writing CDR data to the database is 10 minutes, enter 600 in this field. The script will then query for calls that ended 10 minutes ago, rather than for calls that ended at the current time.
Event severity when failed calls exceed the threshold	Set the severity level, from 1 to 40, to indicate the importance of the event. The default is 15.
Event severity when no records found	Set the severity level for an event in which the query finds no records. This is not the same event as finding no failed calls; this means there were no CDR records in the database for the given query. Accept the default of **0** if you do not want to raise an event. **NOTE:** Set this parameter only to verify CDRs are actually being collected in a timely manner.

19.5.4 Diagnosing VoIP Quality

You can trigger NetIQ Vivinet Diagnostics to run a diagnosis of VoIP quality between two phones or two endpoints. A diagnosis is performed when one of the following Knowledge Scripts determines VoIP quality or call quality is poorer than a specified threshold:

- CallQuality. Vivinet Diagnostics can diagnose the problem when jitter, latency, and percentage of lost data exceed their thresholds.
- CallFailures. Vivinet Diagnostics can diagnose the problem when the number of failed calls exceeds its threshold.

The Action script runs by default only if Vivinet Diagnostics version 1.1 or later is installed on the computer on which the script is running.

For more information about Vivinet Diagnostics and VoIP quality diagnoses, see the *User Guide for Vivinet Diagnostics* and the Help for the Action_DiagnoseVoIPQuality Knowledge Script.

To trigger Vivinet Diagnostics:

1. On the Actions tab, click **Properties**.
2. Enter values for all parameters. For more information about the parameter values, click **Help** on the Properties for Action_DiagnoseVoIPQuality dialog box.
3. Continue entering values on the other tabs of the Properties dialog box, or click **OK** to run the job.

19.5.5 Termination Codes

Termination Code	Description	Explanation
0	No error	No error.
1	Unallocated (unassigned) number	Indicates the called party cannot be reached because, although the called party number is in a valid format, it is not currently allocated (assigned).
2	No route to specified transit network (national use)	Indicates one of the following: • The equipment sending this code has received a request to route the call through a particular transit network it does not recognize. The equipment does not recognize the transit network either because the transit network does not exist or because the transit network exists but does not serve the equipment that is sending the code. • The prefix 0 is invalid for the entered number.
3	No route to destination	Indicates one of the following: • The called party cannot be reached because the network through which the call has been routed does not service the desired destination. This cause is supported on a network-dependent basis. • A 1 was dialed when not required. Redial without the 1.
4	Send special information tone	Indicates one of the following: • The prefix 1 is not required for this number. • The called party cannot be reached for reasons are of a long-term nature. The special information tone should be returned to the calling party.
5	Misdialed trunk prefix (national use)	Indicates the erroneous inclusion of a trunk prefix in the called party number.
6	Channel unacceptable	Indicates a called user cannot negotiate for a B-channel other than that specified in the SETUP message.
7	Call awarded and being delivered in an established channel	Indicates the user has been awarded the incoming call and Indicates the call is being connected to a channel (such as packet mode or X.25 virtual calls) already established to that user for similar calls.
8	Pre-emption	Indicates a call has been preempted.
9	Preemption - circuit reserved for reuse	Indicates a call has been preempted because the circuit is reserved for reuse.

Termination Code	Description	Explanation
16	Normal call clearing	Indicates normal call clearing has occurred.
17	User busy	Indicates the called party is unable to accept another call because the user busy condition has been encountered. Code 17 may be generated by the called user or by the network. In the case of user-determined user busy, it is noted the user equipment is compatible with the call.
18	No user responding	Indicates a called party does not respond to a call establishment message with either an alerting or connect indication within the allotted prescribed period of time (before timer T303 or T310 has expired).
19	No answer from user (user alerted)	Indicates the called user has provided an alerting indication, but not a connect indication within a prescribed period of time (before timer T301 has expired).
20	Subscriber absent	Indicates one of the following: • A mobile station has logged off. • Radio contact is not obtained with a mobile station. • A personal telecommunications user is temporarily not addressable at any user-network interface.
21	Call rejected	Indicates one of the following: • The equipment sending this cause does not wish to accept the call, although it could have accepted the call because it is neither busy nor incompatible. • May be generated by the network, indicated the call was cleared due to a supplementary service constraint.
22	Number changed	Indicates the called party number indicated by the calling party is no longer assigned. The new called party number may optionally be included in the diagnostic field. If a network does not support this cause, cause #1 shall be used.
26	Non-selected user clearing	Indicates the user has not been awarded the incoming call.
27	Destination out of order	Indicates the destination indicated by the user cannot be reached because the interface to the destination is not functioning correctly. The term "not functioning correctly" Indicates a signal message was unable to be delivered to the remote party, as in the following examples: • Physical layer or data link layer failure at the remote party • User equipment off-line
28	Invalid number format (address incomplete)	Indicates one of the following: • The called party cannot be reached because the called party number is not in a valid format or is not complete. • The user should be returned a Special Intercept Announcement.
29	Facility rejected	Indicates one of the following: • The network cannot provide the requested facility. • A user in a special business group, such as a Centrex, dialed an undefined code.

Termination Code	Description	Explanation
30	Response to STATUS ENQUIRY	Indicates one of the following: • This cause is included in the Status Message when the reason for sending the Status Message was the previous receipt of a Status Enquiry message. • A user from outside a basic business group, such as a Centrex, has violated an access restriction feature.
31	Normal, unspecified	Used to report a normal event only when no other cause in the normal class applies.
34	No circuit/channel available	Indicates no appropriate circuit or channel is available to handle the call.
38	Network out of order	Indicates the network is not functioning correctly and the condition is likely to last a relatively long time. Immediately re-attempting the call is not likely to be successful.
39	Permanent frame mode connection out of service	Indicates a permanent connection was terminated, probably due to equipment failure.
40	Permanent frame mode connection operational	Indicates a permanent connection is operational again. The connection was previously terminated, probably due to equipment failure.
41	Temporary failure	Indicates the network is not functioning correctly and the condition is not likely to last a long time. The user may wish to attempt another call almost immediately. May also indicate a data link layer malfunction locally or at the remote network interface, or a call was cleared due to protocol error(s) at the remote network interface.
42	Switching equipment congestion	Indicates the switching equipment generating this cause is experiencing a period of high traffic.
43	Access information discarded	Indicates the network is unable to deliver user information (such as user-to-user information, low-level compatibility, or sub-address) to the remote users as requested.
44	Requested circuit/channel not available	Indicates the other side of the interface cannot provide the circuit or channel indicated by the requesting entity.
46	Precedence call blocked	Indicates the remote device that was called is busy.
47	Resource unavailable, unspecified	Indicates one of the following: • No other cause in the resource unavailable class applies. • The original destination is unavailable. Invoke redirection to a new destination.
49	Quality of Service not available	Indicates the network cannot provide the requested Quality of Service. May be a subscription problem.
50	Requested facility not subscribed	Indicates this facility is unavailable because the user has not subscribed to it.
53	Service operation violated	Indicates the user has violated the service operation.

Termination Code	Description	Explanation
54	Incoming calls barred	Indicates the user will not accept the call delivered in the SETUP message.
55	Incoming calls barred within CUG (Closed User Group)	Indicates the network does not allow the user to receiver calls.
57	Bearer capability not authorized	Indicates the user has requested a bearer capability that is implemented by the equipment that generated this cause, however the user is not authorized to use it. This common problem is caused by incorrect Telco provisioning of the line at the time of installation.
58	Bearer capability not presently available	Indicates the user has requested a bearer capability that is implemented by the equipment that generated this cause, however the bearer capability is unavailable at the present time. This problem may be due to a temporary network problem or a subscription problem.
62	Inconsistency in designated outgoing access information and subscriber class	Indicates an inconsistency in the designated outgoing access information and subscriber class.
63	Service or option not available, unspecified	Indicates a service or option is not available. Used only when no other cause in this class applies.
65	Bearer capability not implemented	Indicates the equipment sending this cause does not support the requested bearer capability.
66	Channel type not implemented	Indicates the called party has reached an unsupported channel type.
69	Requested facility not implemented	Indicates the network (or node) does not support the requested bearer capability and therefore cannot be accessed at this time.
70	Only restricted digital information bearer capability is available (national use)	Indicates the calling party has requested an unrestricted bearer service, however the equipment sending this cause only supports the restricted version of the requested bearer capability.
79	Service or option not implemented, unspecified	Indicates a service or option was not implemented. Used only when no other cause in this class applies.
81	Invalid call reference value	Indicates the equipment sending this cause has received a message with a call reference that is not currently in use on the user-network interface. This value applies only if the call reference values 1 or 2 octets long and is not the global call reference.
82	Identified channel does not exist	Indicates the equipment sending this cause has received a request to use a channel that is not active on the interface for a call.
83	A suspended call exists, but this call identity does not	Indicates a suspended call exists but the call's identity does not.
84	Call identity in use	Indicates a call identity is in use.
85	No call suspended.	Indicates no call is suspended.

Termination Code	Description	Explanation
86	Call having the requested call identity has been cleared	Indicates the call having the requested call identity has cleared.
87	User not member of CUG (Closed User Group)	Indicates the call was not completed, probably due to one of the following reasons: • The dialed number is incorrect • The user is not authorized to use (or has not subscribed to) the requested service • User is using a service that the remote device is not authorized to use
88	Incompatible destination	Indicates the equipment sending this cause has received a request to establish a call that has low layer compatibility, high layer compatibility, or other compatibility attributes (such as data rate or DN subaddress), which cannot be accommodated. This call can be returned by a switch to a CPE when trying to route a call to an incompatible facility, or one without a data rate.
90	Destination number missing and DC not subscribed Nonexistent CUG (Closed User Group)	Indicates the call was not completed, probably due to one of the following reasons: • The dialed number is incorrect • The user is not authorized to use (or has not subscribed to) the requested service • User is using a service that the remote device is not authorized to use
91	Invalid transit network selection (national use)	Indicates an invalid transit network selection has been requested.
95	Invalid message, unspecified	Indicates the entity sending this cause has received an invalid message. Used when no other cause in this class applies.
96	Mandatory information element is missing	Indicates the equipment sending this cause has received a message that is missing an information element that must be present in the message before the message can be processed.
97	Message type non-existent or not implemented	Indicates one of the following: • The equipment sending this cause has received with a message type it does not recognize. Either the message is not defined, or it is defined and not implemented by the equipment sending this cause. • A problem with the remote configuration or with the local D-channel.
98	Message is not compatible with the call state, or the message type is non-existent or not implemented	Indicates one of the following: • Message received is not compatible with the call state • Message type is non-existent or not implemented

Termination Code	Description	Explanation
99	An information element or parameter does not exist or is not implemented	Indicates the equipment sending this cause has received a message that includes information elements not recognized because either the information element identifier is not defined, or it is defined but not implemented by the equipment sending the cause. However, the information element is not required for the equipment sending the cause to process the message.
100	Invalid information element contents	Indicates the equipment sending this cause has received an information element it has implemented. However, one or more fields of the information elements are coded in such a way (such as truncated, invalid extension bit, invalid field values) that the information element has not been implemented by the equipment that is sending this cause.
101	The message is not compatible with the call state	Indicates one of the following: • The equipment sending this cause has received a message the procedures indicate is not a permissible message to receive at this time. • The switch sending this cause is clearing the call because a threshold has been exceeded for multiple protocol errors during an active call.
102	The call was terminated when a timer expired and a recovery routine was executed to recover from the error	Indicates a procedure has been initiated by the expiration of a timer in associated with error-handling procedures.
103	Parameter non-existent or not implemented - passed on (national use)	Indicates the equipment sending this cause has received a message that includes parameters not recognized because the parameters are defined but not implemented by the equipment sending the cause. The parameters were ignored. In addition, if the equipment sending this cause is an intermediate point, this cause Indicates the parameters were passed on unchanged.
110	Message with unrecognized parameter discarded	Indicates the equipment sending this cause has discarded a received message that includes a parameter that is not recognized.
111	Protocol error, unspecified	Reports a protocol error event only when no other cause in this class applies.This cause may be displayed if the user failed to dial a 9 or an 8 for an outside line. In addition, this cause may be returned in the event of certain types of restrictions as to number of calls.
126	Call split	A Cisco-specific code. Indicates a call was terminated during a transfer operation because it was split off and terminated (not part of the final transferred call). This code can help determine which calls were terminated as part of a transfer operation.
127	Internetworking, unspecified	Indicates an internetworking call (usually a call to SW56 service) has ended. May also be seen in the event of a non-specific rejection by a long distance carrier.

19.6 CallQuality

Use this Knowledge Script to monitor Call Management Records (CMRs) for information about the amount of data that is sent and received, and for information about jitter, latency, lost data, and listening MOS.

This script raises an event if a monitored value exceeds or falls below the threshold you set. In addition, this script generates data streams for average jitter, latency, lost data (%), and average and minimum listening MOS.

Cisco CallManager defines lost data, jitter, latency, and listening MOS as follows:

- *Lost data* equals the total number of real-time transport protocol (RTP) data packets that have been lost since the beginning of reception. This number is defined as the number of packets that were expected minus the number of packets that were actually received. The number of packets received includes those that were late or duplicates. Packets that arrive late are not counted as lost; the presence of duplicate packets could result in a negative lost data amount. AppManager records any negative value as zero (0).
- *Jitter* is an estimate of the statistical variance of the RTP data packet interarrival time, measured in milliseconds and expressed as an unsigned integer. Interarrival jitter is the mean deviation (smoothed absolute value) of the difference in packet spacing at the receiver compared to the sender for a pair of packets.
- *Latency* is an estimate of network latency, expressed in milliseconds. Latency is the average value of the difference between the NTP time stamp indicated by the senders of the RTCP messages and the NTP timestamp of the receivers, measured when the messages are received. In a CMR, the average is obtained by adding all of the estimates, then dividing by the number of RTCP messages that have been received.
- *Listening MOS* (Mean Opinion Score) is an overall score representing the quality of a call. The MOS is a number between 1 and 5. A MOS of 5 is excellent; a MOS of 1 is unacceptably bad. In a CMR, the MOS is based on measured items plus jitter buffer size. The jitter buffer size is constant based on the codec. The term "listening" indicates the MOS value does not include "conversational" characteristics such as delay.

NOTE:

- When a Subscriber loses its connection to the Publisher, it stores its CMR data locally until the connection is restored. If the connection is not restored within the collection interval, this script may not monitor some calls.
- When a Subscriber is flooded with calls, it throttles the number of calls that get returned to the Publisher at one time; some calls may not get monitored.
- The clocks on the Subscriber must be synchronized with those of the Publisher.
- CallManager writes CMRs only for Cisco IP phones and for gateways that use the MGCP (Media Gateway Control Protocol) to interface with CallManager.

19.6.1 Resource Object

CCM Publisher. Although you can run this script on the parent CallManager object, it will actually run only on the Publisher.

19.6.2 Default Schedule

By default, this script runs every five minutes.

19.6.3 Troubleshooting Hint

You can use this script as a troubleshooting tool for checking problems with an individual extension. Set the Schedule to "Run Once," set *Maximum acceptable jitter* to "**0**," set *Include call details* to "**Yes**," set *Call disconnect time range* to cover the time when the poor quality calls occurred, and set *Directory number to filter by* to the extension that has the problems. The details that are returned will include the IP address of the phone extension displayed as a link. If the phone supports it, click on this link to reveal some lower-level details about the phone.

19.6.4 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Job Failure Notification	
Event severity when job fails	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the CallQuality job fails. The default is 5.
CallManager database user name	Provide the user login account required to access the CallManager SQL Server database. Leave this field blank to accept the default Cisco login account: `CiscoCCMCDR`. If you changed the default password for `CiscoCCMCDR`, or want to use a different login account, configure the login and password using AppManager Security Manager before running this script. On the SQL tab of Security Manager, provide the IP address or hostname of the CallManager **SQL Server** computer, as well as the **SQL Login Name** and **SQL Login password**.
Use Windows authentication?	Select **Yes** to use Windows authentication to access the Publisher database. If you enable this parameter, the SQL user name is ignored. The `NetIQmc` service must be running with the proper authentication to access the database. The default is Yes.

Parameter	How to Set It
Include call details?	Select **Yes** to include details for up to 50 calls in the Message tab of the Event Properties dialog box. The default is Yes. The call details can include any or all of the following: • Originating Party Device Name (If running on CallManager 3.1) • Originating Party Directory Number • Originating Party Partition • Originating Party CallManager Node ID • Time the call was completed • Jitter • Latency • Lost Data Percentage • Packets Sent • Packets Received • Packets Lost • Originating Party IP address • Originating Party codec • Destination Party Device Name (If running on CallManager 3.1) • Destination Party Directory Number • Destination Party Partition • Destination Party CallManager Node ID • Destination Party IP address • Destination Party codec • Call Duration
Monitor Jitter, Latency, and Percent Lost Data	
Event Notification	
Raise event if jitter, latency, or percent lost data exceeds threshold?	Select **Yes** to raise an event if the jitter, latency, or percent lost data values exceed the thresholds you set. The default is Yes.
Threshold - Maximum acceptable jitter	Specify the maximum amount of jitter that must occur before an event is raised. The default is 60 milliseconds. **NOTE:** You can trigger Vivinet Diagnostics to diagnose the problem indicated by an event in which the jitter threshold is exceeded. For more information, see “Diagnosing VoIP Quality” on page 835.
Threshold - Maximum acceptable latency	Specify the maximum amount of latency that must occur before an event is raised. The default is 400 milliseconds. **NOTE:** You can trigger Vivinet Diagnostics to diagnose the problem indicated by an event in which the latency threshold is exceeded. For more information, see “Diagnosing VoIP Quality” on page 835.
Threshold - Maximum acceptable percent lost data	Specify the maximum percentage of data that must be lost before an event is raised. The default is 1%. **NOTE:** You can trigger Vivinet Diagnostics to diagnose the problem indicated by an event in which the percentage lost data threshold is exceeded. For more information, see “Diagnosing VoIP Quality” on page 835.

Parameter	How to Set It
Threshold - Minimum lost packets, if lost data threshold is exceeded	Set this threshold *only* if you set a threshold for *Maximum acceptable percent lost data*. Use this parameter on occasions when lost data does exceed the threshold you set, but you do not want to raise an event unless a specific number of packets has also been lost. The default is 0 packets. For example, you have set *Maximum acceptable percent lost data* to 10%, and you have set this parameter to 5 packets. If the amount of lost data is 15%, but the number of lost packets is only 2, no event is raised. An event is raised only if the percentage of lost data AND the number of lost packets exceed the thresholds you set.
Event severity if jitter, latency, or percent lost data exceeds threshold	Set the severity level, from 1 to 40, to indicate the importance of an event in which one or more of the jitter, latency, and lost data thresholds have been exceeded. The default is 15.
Data Collection	
Collect data for jitter, latency, and percent lost data?	Select **Yes** to collect data for reports and graphs. If enabled, data collection generates data streams for average jitter, latency, and percent lost data for the monitoring interval. **NOTE:** Some third-party billing applications remove CDR records from the CallManager database. If records are removed before the CallQuality script has a chance to run, the script will not collect any data.
Monitor Listening MOS	
Monitor Average Listening MOS	
Event Notification	
Raise event if average listening MOS for any call falls below threshold?	Select **Yes** to raise an event if the average listening MOS for any call falls below the threshold you set. The default is Yes.
Threshold - Average listening MOS	Specify the minimum value for average listening MOS that must occur for *any* call to prevent an event from being raised. The default is 3.60. Average listening MOS is defined as the running average of MOS scores (recorded at 8-second intervals) observed since the beginning of the call.
Event severity if average listening MOS for any call falls below threshold	Set the severity level, from 1 to 40, to indicate the importance of an event in which the average listening MOS for any call falls below the threshold. The default is 15.
Data Collection	
Collect data for average listening MOS?	Select **Yes** to collect data for reports and graphs. If enabled, data collection generates a data stream for average listening MOS for the monitoring interval.
Monitor Minimum Listening MOS	
Event Notification	
Raise event if minimum listening MOS for any call falls below threshold?	Select **Yes** to raise an event if the lowest listening MOS for any call falls below the threshold you set. The default is unselected.

Parameter	How to Set It
Threshold - Minimum listening MOS	Specify the lowest listening MOS value that must occur for *any* call to prevent an event from being raised. The default is 3.60. Minimum listening MOS is defined as the worst of the MOS scores (recorded at 8-second intervals) observed since the beginning of the call.
Event severity if minimum listening MOS for any call falls below threshold	Set the severity level, from 1 to 40, to indicate the importance of an event in which the lowest listening MOS for any call falls below the threshold. The default is 15.
Data Collection	
Collect data for lowest listening MOS?	Select **Yes** to collect data for reports and graphs. If enabled, data collection generates a data stream for lowest listening MOS for the monitoring interval.
Query Filters	
Directory number to filter by	Specify a directory number to filter the calls that get monitored. The default is to monitor all calls. You can specify a group of directory numbers by using a '%' as a wildcard. For example, to monitor all the directory numbers that begin with 31, enter 31%. **NOTE:** This parameter returns results only if the directory number you enter is the originating number. No results are returned if you enter the destination number.
Minimum call duration filter	Use this parameter to filter out calls whose duration is less than the specified value. The default is 0 seconds.
No Records Found Notifications	
Event severity when no records found	Set the severity level, from 1 to 40, to indicate the importance of an event in which no jitter, latency, or percent lost data records are found. Accept the default of **0** if you do not want to raise an event for this incident.
Event severity when no MOS records found	Set the severity level, from 1 to 40, to indicate the importance of an event in which no MOS records are found. Accept the default of **0** if you do not want to raise an event for this incident.
Troubleshooting	
Select call disconnect time range	Select a **Specific** (fixed) or **Sliding** date/time range in which to search for call failures. The default is Specific.
Query timeout	Specify the maximum number of seconds it can take a query to run. The default is 10 seconds. **NOTE:** This script runs three queries in order to get data for each interval.

Parameter	How to Set It
Monitoring offset	Because CallManager can have a delay when writing records to the database, a query may not return any call failures if the script is monitoring only the past few seconds. You can choose to have the script offset the monitoring period in order to capture those failures that occurred earlier. The default is 45 seconds. For example, if the delay for writing CDR data to the database is 10 minutes, enter 600 in this field. The script will then query for calls that ended 10 minutes ago, rather than for calls that ended at the current time.

19.7 CallsActive

Use this Knowledge Script to monitor the number of active calls. This script raises an event if the number of active calls exceeds the threshold you set.

19.7.1 Resource Object

CCM Call Processor

19.7.2 Default Schedule

By default, this script runs once each day.

19.7.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if threshold is exceeded?	Set to **y** to raise an event if the threshold is exceeded. The default is y.
Collect data?	Set to **y** to collect data about active calls for reports and graphs. The default is n.
Threshold - Maximum active calls	Specify the maximum number of calls that can be active before an event is raised. The default is 500 calls.
Event severity when threshold is exceeded	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.

19.8 CallsAttemptedByPhone

Use this Knowledge Script to monitor the number of calls attempted by an individual phone during an interval. This script raises an event if the number of attempted calls exceeds the threshold you set.

19.8.1 Resource Object

CCM Phone folder

19.8.2 Default Schedule

By default, this script runs every 30 minutes.

19.8.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if threshold is exceeded?	Set to **y** to raise an event if the threshold is exceeded. The default is y.
Collect data?	Set to **y** to collect data about attempted calls for reports and graphs. The default is n.
Phones, separated by comma w/no space	Provide a comma-separated list of the names of the phones you want to monitor for attempted calls.
Threshold - Maximum attempted calls	Specify the maximum number of calls that can be attempted before an event is raised. The default is 100 calls.
Event severity when threshold is exceeded	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the threshold is exceeded. The default is 25.

19.9 CallsInProgress

Use this Knowledge Script to monitor the number of calls in progress and the percentage of in-progress calls that are active. A call is considered "in-progress" as soon as the receiver is lifted. A call is considered "active" once a connection is made.

This script raises an event if the number of in-progress calls exceeds the threshold or if the percentage of active in-progress calls falls below the threshold.

This script is a member of a Recommended Knowledge Script Group. For more information, see "Recommended Knowledge Script Groups" on page 1057.

19.9.1 Resource Object

CCM Call Processor

19.9.2 Default Schedule

By default, this script runs once each day.

19.9.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if threshold is breached?	Set to **y** to raise an event if a monitored value exceeds or falls below the threshold you set. The default is y.
Collect data for calls in progress?	Set to **y** to collect data about in-progress calls for reports and graphs. The default is n.
Threshold - Maximum calls in progress	Specify the maximum number of calls that can be in progress before an event is raised. The default is 100 calls.
Event severity when in-progress calls exceed the threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of in-progress calls exceeds the threshold. The default is 25.
Collect data for active calls?	Set to **y** to collect data about active in-progress calls for reports and graphs. The default is n.
Threshold - Minimum active calls	Specify the minimum percentage of calls that can be active before an event is raised. The default is 10%. **NOTE:** By seeing how many in-progress calls are active, you can determine whether any in-progress calls are simply stuck off-hook.
Event severity when active calls fall below the threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the percentage of active in-progress calls falls below the threshold. Accept the default of **0** if you do not want to raise an event.

19.10 CCM_CheckFirmware

Use this Knowledge Script to detect any device that has been configured with a non-default firmware load. This script returns the number of devices of each device type — the same information you would retrieve when accessing the Cisco CallManager Administration Web page.

This script does not determine which firmware load a device is running.

Only AppManager administrators should run this script.

19.10.1 Resource Object

CCM Publisher

19.10.2 Default Schedule

By default, this script runs once each day.

19.10.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Threshold - Maximum devices with non-default firmware load	Specify the maximum number of devices, from all selected device types, that can be configured for a non-default firmware load before an event is raised. The default is 0 devices.
Raise event when threshold is not exceeded?	Set to **y** to raise an event when the threshold is *not* exceeded. The default is y.
Event severity when threshold is not exceeded	Set the event severity level to indicate the importance of an event in which the threshold is *not* exceeded. Enter **0** if you do not want to raise an event for this situation. The default is 25. For more information, see "Event Messages for CCM_CheckFirmware" on page 852.
Event severity when threshold is exceeded	Set the event severity level to indicate the importance of an event in which the threshold is exceeded. Enter **0** if you do not want to raise an event for this situation. The default is 15.

Parameter	How to Set It
Check · · · types?	Set to n if you do not want to check any of the following types of devices. The default is y. • Analog Access • Analog Access WS-X6624 • Cisco 12 S • Cisco 12 SP • Cisco 12 SP+ • Cisco 30 SP+ • Cisco 30 VIP • Cisco IP Phone 7905 • Cisco IP Phone 7910 • Cisco IP Phone 7935 • Cisco IP Phone 7940 • Cisco IP Phone 7960 • Cisco ATA 186 • Cisco Conference Bridge WS-X6608 • Digital Access WS-X6608 • Digital Access+ • Media Termination Point WS-X6608 • VGC Gateway • 14-Button Line Expansion Module

19.10.4 Event Messages for CCM_CheckFirmware

Following are two common error messages, accompanied by an explanation, a likely cause, and any operator action that may be needed.

Devices using non-default firmware load exceed the threshold.

Explanation: The number of devices that are configured with a non-default firmware load is greater than the specified threshold. See the detailed event message for details of the devices not configured with a default firmware load.

Likely cause: Normal message when the threshold has been crossed.

Operator action: Notify your Cisco CallManager administrator that there are devices that are not configured for the default firmware load.

Internal error encountered.

Explanation: Errors were encountered while checking one or more of the selected devices. See the detailed event message for details about the error.

Likely cause: In most cases this message Indicates a COM interface was not available, either because the COM object has not been installed or is not registered.

Operator action: Verify the `dblx.dll` is installed and registered on the CallManager computer.

19.11 CCM_CpuHigh

Use this Knowledge Script to monitor the CPU resources that application processes are consuming. If application CPU utilization exceeds the thresholds you set, an event is raised. The script monitors CPU usage for each process individually and the total CPU usage for all processes. If a process is not found, the script assumes the process is not running, and reports zero as the CPU result.

19.11.1 Resource Object

CCM parent object

19.11.2 Default Schedule

By default, this script runs every 15 minutes.

19.11.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if threshold is exceeded?	Set to **y** to raise an event if any threshold is exceeded. The default is y.
Collect data?	Set to **y** to collect data about CPU usage for graphs and reports. The default is n.
Event severity when threshold is exceeded	Set the severity level, from 1 to 40, to indicate the importance of an event in which the threshold is exceeded. The default is 8.
Monitor the Cisco CallManager process?	Set to **y** to monitor the status of the Cisco CallManager process. The default is y.
Threshold - Maximum CPU for CallManager	Specify the maximum amount of CPU usage for the Cisco CallManager process that can occur before an event is raised. The default is 80%.
Monitor other Cisco processes?	Set to **y** to monitor the status of other Cisco processes. The default is n.
Threshold - Maximum CPU for other processes?	Specify the maximum amount CPU usage for other Cisco processes that can occur before an event is raised. The default is 20%.

19.12 CCM_DeviceStatus

Use this Knowledge Script to monitor the status of key devices within a cluster. The possible statuses are:

- **Registered**. This status indicates the device is available
- **Unregistered**. This status indicates a device that was previously registered with CallManager has become unregistered. This status may be generated as part of a normal unregistration event, or can be due to another reason such as loss of keepalives.
- **Rejected**. This status indicates CallManager has rejected the registration for the device. This script detects this status only if the device was at one time registered to the CallManager but a subsequent registration attempt was rejected.
- **Unknown**. This status indicates the device has not been registered to any CallManagers in the cluster for a long time, or the device was added to a CallManager but never registered, or the CallManager RIS service is not operational.

NOTE: Phones that are added while this script is running will not be monitored.

The first time you run this script, it builds a device list from the criteria you have selected. At each subsequent interval, the script checks the status of these devices. If the number or percentage of these devices that are registered does not meet the threshold you define, an event is raised. The device list is not rebuilt each time you run this script. Therefore, if you add a new device, delete a device, or change device details, the changes will *not* be picked up by this script unless you stop it and then restart it. If you delete a device, the status will change to "Unknown," but the device will remain in the list until you stop and restart the script.

If you enter multiple selection criteria and the selections find the same device or devices, there will be duplicate entries in the list of devices to be monitored. This is working as designed — if you select by directory numbers, and a device has more than one directory number, you will get duplicate entries for that device.

Different *Select By* choices will build different lists of devices to be monitored even if you select the same *Device Type*. For example, if you select *DeviceName*, the list will contain all of the directory numbers for each device with that device type. If you select *DirectoryNumber*, each row in the list will contain only a single directory number. If a device has multiple directory numbers, that device will be listed multiple times.

TIP: This script uses several COM modules. There is a one-time cost of about 7-10M of memory and CPU usage of around 30-40% the first time the script is run.

19.12.1 Prerequisite

This script relies on the CallManager RIS (Real-Time Information Server) function to be working properly. If this function is not working on all the CallManagers in a cluster, this script may not generate accurate results. Verify the Cisco Database Layer Monitor and the Cisco RIS Data Collector services are running on all the CallManagers in the clusters.

Cisco has documented the following for CallManager:

The Real-Time Information Server (RIS) collects, distributes, and maintains real-time Cisco CallManager information and provides an interface through which the Cisco RIS Data Collector service and the SNMP Agent retrieve that information. One RIS exists on each node that contains the Cisco CallManager service. The Cisco RIS Data Collector service provides an interface for applications, such as Cisco CallManager Serviceability and the Cisco CallManager Administration, to retrieve information that is stored in all RIS nodes in the cluster.

- Cisco recommends the Cisco RIS Data Collector service reside on every server in the Cisco CallManager cluster.
- Cisco RIS Data Collector service requires the Cisco Database Layer Monitor service.

19.12.2 Examples of Using CCM_DeviceStatus

If you use centralized processing, you would benefit from using this script. You could monitor a group of devices at the remote site and then raise an event if a certain number of those devices were not registered.

In a second scenario, you could verify the phones in public places (such as conference rooms) have not been taken off the network. Many times, employees will use a public port for their laptops and forget to put the phone back online.

You can also use this script for troubleshooting. For example, you could retrieve the IP address of all the devices with a certain directory number.

19.12.3 Resource Object

CCM Publisher

19.12.4 Default Schedule

By default, this script runs every one minute.

19.12.5 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if threshold not met?	Set to **y** to raise an event if the threshold is not met. The default is y. The detailed message for the event will contain the following information about each device that is not registered: • Device Name • Description • Directory number(s) • IP address (if available) • Status • CallManager node where device was registered (if available) • Model • Device Pool (if available) • Calling Search Space (if available) For more information, see "Examples of Using CCM_DeviceStatus" on page 855.

Parameter	How to Set It
Collect data?	Set to **y** to collect data for graphs and charts. The default is n. The data collected is the number of devices that are being monitored and the number of those devices that are registered.
Event severity when threshold is not met	Set the severity level, from 1 to 40, to indicate the importance of an event in which a threshold is not met. The default is 10.
Device to monitor	Select the type of devices to monitor. Valid values are: • Phone (the default) • MGCP_GatewayDevice • CtiRoutePoint • VoiceMailPort • ConferenceBridge • MusicOnHoldDevice • MediaTerminationPoint
Select by	Choose the type of the selection criteria to be used to get the list of devices to monitor. Note that some criteria may not make sense for every device type. For example, you would not want to select by Directory Numbers if the Device Type is Conference Bridges. Valid values are: • DeviceName (the default) • DirectoryNumber • Description • DevicePool • CallingSearchSpace
Selection criteria	Enter the selection criteria for the devices to be monitored. You can specify the actual item or you can specify a pattern by using the * wildcard. For example, to monitor all the devices with device names that begin with SEP, enter `SEP*`. The default is *, which Indicates you want to monitor all devices. You can enter multiple items by separating each item with a comma. For example: `SEP0009A*,SEP0009B*` The items must be the same type as the *Select By* parameter. So if *Select By* is **Device Name**, the items must be device names or patterns. If *Select By* is **Directory Number**, the items must be directory numbers or patterns. **NOTE:** If you enter a file path in *Full path to file with list of selection criteria*, ignore this parameter.

Parameter	How to Set It
Full path to file with list of selection criteria	Enter the full path to a file on the agent computer containing a list of the selection criteria. The file should contain the selection criteria on one or more lines. Each line can have multiple items, separated by commas. For example: • `SEP0009A*,SEP0009B*` • `SEP999999994000,SEP999999994001` • `SEP00044*` The items must be the same type as the *Select By* parameter. So if *Select By* is **Device Name**, the items must be device names or patterns. If *Select By* is **Directory Number**, the items must be directory numbers or patterns. **NOTE:** If you enter a file path, ignore the *Selection Criteria* parameter.
Maximum number of devices to monitor	Enter the maximum number of devices to be monitored. Only this number of devices will be monitored even if the selection criterion returns more than this number. Enter a number between 1 and 250. The default is 100 devices. **NOTE:** If the selection criterion does return more devices than the maximum number of devices to monitor, this script generates an event issued warning that this situation has occurred.
Raise event with current status?	Enter **y** to generate an informational event containing the current status of the devices selected the first time this script runs. The default is y. The following details will be returned about each device: • Device Name • Description • Directory number(s) • IP address (if available) • Status • CallManager node where device is\was registered (if available) • Model • Special firmware load • Device Pool (if available) • Calling Search Space (if available) If you set this parameter to y, the first time the script is run an informational event will be generated containing the current status and details of all the monitored devices. The details of this informational event can be formatted in either XML or csv.
Format status event in XML?	Set to **y** to format the informational event containing the current status in XML. The default is y. If you use XML for the event, it will not be sent to any Actions that are defined for the script. If you want this information sent to an Action, set this parameter to n. The detailed message will then be formatted in .csv.
Threshold type	Select whether you want to monitor for a **Percentage** threshold or a **Number** threshold. The default is Percentage.
Threshold - Minimum % registered key devices	Specify the minimum percentage of devices that must have a status of "Registered" before an event is raised. The default is 75%.

Parameter	How to Set It
Threshold - Minimum # registered key devices	Specify the minimum number of devices that must have a status of "Registered" before an event is raised. The default is 0 devices.
Event severity when key devices cross threshold and then return	Set the severity, from 1 to 40, of an event that is raised when the number or percent of key devices registered was previously below the threshold but now is within acceptable limits. Enter **0** if you do not want to raise an event. The default is 20.

19.12.6 Event Messages for CCM_DeviceStatus

Following are common error messages, accompanied by an explanation, a likely cause, and any operator action that may be needed.

Internal error encountered.

Explanation: An unrecoverable error was encountered. See the detailed event message for details about the error.

Likely cause: In most cases this message Indicates a COM interface was not available, either because the COM object has not been installed or is not registered.

Operator action: Verify the `dblx.dll` and `risx.dll` are installed and registered on the CallManager computer.

Initial device status.

Explanation: "y" was entered for the *Generate an event with the initial status* parameter. See the detailed event message for the status.

Likely Cause: See explanation.

Operator Action: No action is required.

 # key devices registered low.

Explanation: The number of devices you have selected to be monitored that have a status of "Registered" does not meet the threshold. See the detailed event message for a list of the devices that are not "Registered."

Likely Cause: If one or two devices are unavailable, it probably means someone has unplugged them from the network. If a large number of devices is unavailable, either there is a network problem or a failover may be in progress.

Operator Action: Verify the devices are plugged into the network and are operational. In the case of a large number of devices becoming unavailable, check to see whether a failover has occurred. In the case of a failover, the devices should get re-registered to the backup CallManager and should become available again. If there is a network problem, contact the network administrator.

% key devices registered low.

Explanation: The percentage of devices you have selected to be monitored that have a status of "Registered" does not meet the threshold. See the detailed event message for a list of the devices that are not registered.

Likely Causes: If one or two devices are unavailable, it probably means someone has unplugged them from the network. If a large number of devices are unavailable, either there is a network problem or a failover may be in progress.

Operator Action: Verify the devices are plugged into the network and are operational. In the case of a large number of devices becoming unavailable, check to see whether a failover has occurred. In the

case of a failover, the devices should get re-registered to the backup CallManager and should become available again. If there is a network problem, contact the network administrator.

Syntax error: nothing selected.

Explanation: You must enter input into either the *Selection Criteria* or *File path containing selection criteria* parameter

Likely Cause: All selection parameters are empty.

Operator Action: Enter input into at least one of the selection parameters.

Unable to access device file.

Explanation: The file name entered could not be read. Either the path is inaccessible from the AppManager agent or the file does not exist.

Likely Cause: In most cases this message Indicates the file does not exist.

Operator Action: Verify the file exists and the path is accessible from the AppManager agent.

No devices to monitor.

Explanation: There were no devices found that match the selection criteria entered.

Likely Cause: See explanation.

Operator Action: Change the selection criteria.

Not all devices monitored.

Explanation: The number of devices found that match the selection criteria entered is greater than the maximum number of devices to be monitored. Only the maximum number of devices will be monitored.

Likely Cause: See explanation.

Operator Action: None, if the actual devices that are being monitored meet your objective. If not, change the selection criteria if possible so that a smaller list is returned from the selection.

Some devices not found.

Explanation: Multiple selection criteria were entered and one of the selection criteria did not find any devices.

Likely Cause: Most likely, the selection criteria are being read from a file, which contains one or more selection items or patterns that did not find a match. For example, if the file contains

```
SEP000ABD123,SEP000ABD124
SEP000ADD125,SEP000ABD126
```

and `SEP000ADD125` does not exist, you will get this warning message and only three devices will be monitored.

Operator Action: None, if the actual devices that are being monitored meet your objective. If not, change or remove the selection criterion that is not returning any devices.

19.13 CCM_EventLog

Use this Knowledge Script to monitor event log entries from Cisco CallManager during the past *n* hours. This script raises an event if the log contains the entries you identify.

19.13.1 Example of Using this Script

Cisco CallManager records events to the Windows Application Log under the source of the CallManager process that created the event. For example, a TFTP error is recorded under "Cisco Tftp." However, monitoring the Application Log is a time-consuming process, rendering the Application Log a diagnostic tool used only long after a problem occurs.

Using the CCM_EventLog Knowledge Script to periodically filter the Application Log, you can easily search for events that meet the criteria you specify, such as *Event Source=Cisco CallManager service name* or *Event Category=Error*. AppManager then raises an event with a description of the CallManager-related event.

Searching too many records can be CPU and memory intensive.

19.13.2 Resource Object

CCM parent object

19.13.3 Default Schedule

By default, this script runs every 10 minutes.

19.13.4 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event for log entries?	Set to **y** to raise an event when the log contains entries for which you have filtered. The default is y.
Collect data?	Set to **y** to collect data about log entries for charts and graphs. The default is n.
Separate data?	Set to **y** to separate events entries from different log files into different data streams. If set to n, all event entries matching your filtering criteria are placed in the same data stream and the data detail message may include event entries from multiple log sources. The default is n. For example, if you are monitoring both the System and Application logs, you may want to set this parameter to **y** so that events in the System log are tracked separately from events in the Application log.
Log source	Specify the event log you want to monitor. You can specify multiple event logs, separated by commas. For example: `System,Application`. The default is Application.

Parameter	How to Set It
Type: Error	Set to **y** to monitor for error events. If you set to n, this entry does not raise an event, is not returned in an event detail message, and is not collected as data if you specified **y** for *Collect data*. The default is y.
Type: Warning	Set to **y** to monitor for warning events. If you set to n, this entry does not raise an event, is not returned in an event detail message, and is not collected as data if you specified **y** for *Collect data*. The default is y.
Type: Information	Set to **y** to monitor for information events. If you set to n, this entry does not raise an event, is not returned in an event detail message, and is not collected as data if you specified **y** for *Collect data*. The default is n.
Type: Success Audit	Set to **y** to monitor for success audit events. If you set to n, this entry does not raise an event, is not returned in an event detail message, and is not collected as data if you specified **y** for *Collect data*. The default is n.
Type: Failure Audit	Set to **y** to monitor for failure audit events. If you set to n, this entry does not raise an event, is not returned in an event detail message, and is not collected as data if you specified **y** for *Collect data*. The default is n.
Instructions for filters: To limit the types of entries that raise events and the type of data that is collected, enter a search string that filters the following fields in the event log. The search string can contain criteria used to include entries, exclude entries, or both. • Separate include and exclude criteria with a colon (:). For example, `net:logon`. • Separate multiple include or exclude entries with commas. For example, `finance,sales:corp00,HQ`. • If you are specifying only include criteria, the colon is not necessary. For example, `SQL`. • If you are specifying only exclude criteria, start the search string with a colon. For example, `:defragmentation,cleanup`.	
Event source filter	Specify one or more text strings to look for; separate multiple strings with commas. For example: `NTDS KCC,NTDS General`
Event category filter	Specify one or more text strings to look for; separate multiple strings with commas.
Event ID filter	Specify a single event ID or a range of event IDs; separate multiple entries by commas. For example: `1094,1404-1463`
Event user filter	Specify a single or multiple user names to look for; separate multiple entries by commas. For example: `Pat,Chris,Alex`
Computer filter	Specify a single or multiple computer names to look for; separate multiple entries by commas. For example: `SHASTA,MARS`
Event description filter	Specify a detail description or keywords in the description. The string can contain spaces, underscores, and periods; separate multiple entries with commas. For example: `data loss during system failures,corrupt indices,Inter-Site Transport objects failed`

Parameter	How to Set It
Maximum number of entries per event report	Specify the maximum number of Application log events that can be returned in each event report. For example, if this value is set to 30 and 67 Application log events are found, three event reports are raised: two reports containing 30 events and one report containing seven events. The default is 30. The Message column on the Events tab displays the number of events in each event report, the type of log the events are from, and the event report batch number. The batch number is the sequential number of the event report. Batch numbers start at 1 for each Knowledge Script iteration.
Event severity for log entries	Set the event severity level, from 1 to 40, to indicate the importance of an event. You may want to adjust the severity depending on the types of events for which you are checking. The default is 8.

19.14 CCM_FXOPorts

Use this Knowledge Script to monitor the number of active and in-service FXO (foreign exchange office) ports for this CallManager. This script raises an event if a monitored value exceeds or falls below the threshold you set.

The ports or channels you monitor can be on one or more MGCP gateways.

19.14.1 Resource Object

CCM Call Processor

19.14.2 Default Schedule

By default, this script runs every 10 minutes.

19.14.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if threshold is breached?	Set to **y** to raise an event if either threshold is breached. The default is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default is n.
Suppress event when Role is set to Backup?	Set to **y** to suppress event generation on CallManager resources whose role is set to "backup." The default is y. By suppressing event generation, you can run a script on all CallManager resources without raising an event on a resource that is not actively handling calls.
Event severity when threshold is breached	Set the severity level, from 1 to 40, to indicate the importance of a breached threshold. The default is 15.
Threshold - Maximum active FXO ports	Specify the maximum number of FXO ports that can be active before an event is generated. The default is 10 ports.
Threshold - Minimum in-service FXO ports	Specify the minimum number of FXO ports that can be in service before an event is generated. The default is 0 ports.

19.15 CCM_FXSPorts

Use this Knowledge Script to monitor the number of active and in-service FXS (foreign exchange station) ports for this CallManager. This script raises an event a monitored value exceeds or falls below the threshold you set.

The ports or channels you monitor can be on one or more MGCP gateways.

19.15.1 Resource Object

CCM Call Processor

19.15.2 Default Schedule

By default, this script runs every 10 minutes.

19.15.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if threshold is breached?	Set to **y** to raise an event if either threshold is breached. The default is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default is n.
Suppress event when Role is set to Backup?	Set to **y** to suppress event generation on CallManager resources whose role is set to "backup." The default is y. By suppressing event generation, you can run a script on all CallManager resources without raising an event on a resource that is not actively handling calls.
Event severity when threshold is breached	Set the severity level, from 1 to 40, to indicate the importance of a breached threshold. The default is 15.
Threshold - Maximum active FXS ports	Specify the maximum number of FXS ports that can be active before an event is generated. The default is 10 ports.
Threshold - Minimum in-service FXS ports	Specify the minimum number of FXS ports that can be in service before an event is generated. The default is 0 ports.

19.16 CCM_HealthCheck

Use this Knowledge Script to monitor the status of Cisco CallManager services. This script automatically starts any down service when *Auto-start monitored services* is set to **y**.

This script collects the data used by the Report_ServicesAvailability Knowledge Script.

This script is a member of a Recommended Knowledge Script Group. For more information, see "Recommended Knowledge Script Groups" on page 1057.

19.16.1 Resource Object

CCM parent object

19.16.2 Default Schedule

By default, this script runs every one minute.

19.16.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Collect data?	Set to **y** to enable this script to collect data for reports and graphs. The default is y.
Auto-start monitored service(s)?	Set to **y** to automatically start any of the services you choose to monitor. The default is y.
Event severity when auto-start fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the service is down and AppManager cannot restart it. The default is 5.
Event severity when auto-start succeeds	Set the severity level, from 1 to 40, to indicate the importance of an event in which the service was down and AppManager successfully restarted it. The default is 25.
Event severity when auto-start is set to "n"	Set the severity level, from 1 to 40, to indicate the importance of an event in which the service is down and AppManager has not been set to restart the service. The default is 18.
Event severity when service does not exist	Set the severity level, from 1 to 40, to indicate the importance of an event in which the service does not exist. The default is 15.
Event severity when service is paused	Set the severity level, from 1 to 40, to indicate the importance of an event in which the service is in a paused state. The default is 20. Some services enter a paused state when the system is low on CPU or memory resources. Enter **0** when you do not want to raise an event for this situation.
Monitor Cisco CallManager service?	Set to **y** to monitor the status of Cisco CallManager. The default is y.
Monitor Cisco Database Layer Monitor service?	Set to **y** to monitor the status of Cisco Database Layer Monitor. The default is y.

Parameter	How to Set It
Monitor Cisco TFTP service?	Set to **y** to monitor the status of Cisco TFTP. The default is y.
Monitor Cisco IP Voice Media Streaming App service?	Set to **y** to monitor the status of Cisco IP Voice Media Streaming App. The default is n.
Monitor Cisco Messaging Interface service?	Set to **y** to monitor the status of Cisco Messaging Interface. The default is n.
Monitor Cisco Telephony Call Dispatcher service?	Set to **y** to monitor the status of Cisco Telephony Call Dispatcher. The default is y.
Monitor DC Directory Server service?	Set to **y** to monitor the status of the DC Directory Server service. The default is y.
Monitor Cisco SNMP Data Collector service? (for CallManager 3.0 only services)	Set to **y** to monitor the status of Cisco SNMP Data Collector. The default is n.
Monitor Cisco CTI Manager service?	Set to **y** to monitor the status of Cisco CTI Manager (for CallManager 3.1 and later). The default is n.
Monitor Cisco Extension Mobility Logout service?	Set to **y** to monitor the status of Cisco Extension Mobility Logout (for CallManager 3.1 and later). The default is n.
Monitor Cisco MOH Audio Translator service?	Set to **y** to monitor the status of Cisco MOH Audio Translator (for CallManager 3.1 and later). The default is n.
Monitor Cisco RIS Data Collector service?	Set to **y** to monitor the status of Cisco RIS Data Collector (for CallManager 3.1 and later). The default is n.

19.17 CCM_HeartBeat

Use this Knowledge Script to monitor the CallManager heartbeat. This script raises an event if the heartbeat stops or falls below the specified threshold. A low heartbeat Indicates the CallManager service was stopped and then restarted.

This script is a member of a Recommended Knowledge Script Group. For more information, see "Recommended Knowledge Script Groups" on page 1057.

19.17.1 Resource Object

CCM parent object

19.17.2 Default Schedule

By default, this script runs every one minute.

19.17.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if heartbeat stops or falls below the threshold?	Set to **y** to raise an event when the heartbeat stops or falls below the threshold. The default is y.
Collect data?	Set to **y** to collect data about the heartbeat for reports and graphs. The default is n.
Threshold - Minimum heartbeat	Specify the minimum heartbeat count that can be detected before an event is raised. The default is 500.
Event severity when heartbeat falls below the threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the heartbeat fell below the threshold. The default is 20.
Event severity when heartbeat stops	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the heartbeat stopped. The default is 10.

19.18 CCM_MemByProcess

Use this Knowledge Script to monitor working set memory use for individual CallManager processes, and the total working set memory use for all monitored CallManager processes. This script raises an event if working set memory use exceeds the threshold. If a process cannot be found, no events are generated.

19.18.1 Resource Object

CCM parent object

19.18.2 Default Schedule

By default, this script runs every five minutes.

19.18.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Collect data for memory use by all monitored processes?	Set to **y** to collect data for the total amount of memory being used by all the monitored processes. The default is y.
Threshold - Maximum memory use for all monitored processes	Specify the maximum amount of memory that can be used by all the monitored processes before an event is raised. The default is 512000 KB.
Event severity when total memory use exceeds the threshold	Set the severity level, from 1 to 40, to indicate the importance of an event in which memory use for all monitored processes exceeds the threshold. Enter **0** if you do not want to raise an event. The default is 15.
Collect data for memory use by individual processes?	Set to **y** to collect data for the amount of memory being used by each monitored process.
Event severity when individual memory use exceeds the threshold	Set the severity level, from 1 to 40, to indicate the importance of an event in which memory use for individual processes exceeds the threshold. Enter **0** if you do not want to raise an event. The default is 15.
Monitor the CallManager process?	Set to **y** to monitor memory usage of the Cisco CallManager process. The default is y.
Threshold - Maximum memory use for the CallManager process	Specify the maximum amount of memory that can be used by the Cisco CallManager process before an event is raised. The default is 200000 KB.
Monitor the DC Directory process?	Set to **y** to monitor memory usage of the DC Directory process. The default is y.
Threshold - Maximum memory use for the DC Directory process	Specify the maximum amount of memory that can be used by the DC Directory processes before an event is raised. The default is 100000 KB.
Monitor the CTI Manager process?	Set to **y** to monitor memory usage of the CTI Manager process. The default is y.

Parameter	How to Set It
Threshold - Maximum memory use for the CTI Manager process	Specify the maximum amount of memory that can be used by the CTI Manager process before an event is raised. The default is 50000 KB.
Monitor the Cisco TFTP process?	Set to **y** to monitor memory usage of the Cisco TFTP process. The default is y.
Threshold - Maximum memory use for the Cisco TFTP process	Specify the maximum amount of memory that can be used by the Cisco TFTP process before an event is raised. The default is 50000 KB.
Monitor the Database Layer process?	Set to **y** to monitor memory usage of the Database Layer process (Aupair). The default is y.
Threshold - Maximum memory use for the Database Layer process	Specify the maximum amount of memory that can be used by the Database Layer process before an event is raised. The default is 50000 KB.
Monitor the Telephony Call Dispatcher process?	Set to **y** to monitor memory usage of the Telephony Call Dispatcher process. The default is y.
Threshold - Maximum memory use for the Telephony Call Dispatcher process	Specify the maximum amount of memory that can be used by the Telephony Call Dispatcher process before an event is raised. The default is 50000 KB.
Monitor the CDR Insert process?	Set to **y** to monitor memory usage of the CDR Insert process. The default is n.
Threshold - Maximum memory use for the CDR Insert process	Specify the maximum amount of memory that can be used by the CDR Insert process before an event is raised. The default is 75000 KB.
Monitor the Messaging Interface process?	Set to **y** to monitor memory usage of the Messaging Interface process. The default is n.
Threshold - Maximum memory use for the Messaging Interface process	Specify the maximum amount of memory that can be used by the Messaging Interface process before an event is raised. The default is 50000 KB.
Monitor the Extension Mobility process?	Set to **y** to monitor memory usage of the Extension Mobility process. The default is n.
Threshold - Maximum memory use for the Extension Mobility process	Specify the maximum amount of memory that can be used by the Extension Mobility process before an event is raised. The default is 50000 KB.
Monitor the MOH Audio Translator process?	Set to **y** to monitor memory usage of the MOH (Music On Hold) Audio Translator process. The default is n.
Threshold - Maximum memory use for the MOH Audio Translator process	Specify the maximum amount of memory that can be used by the MOH Audio Translator process before an event is raised. The default is 50000 KB.
Monitor the RIS Data Collector process?	Set to **y** to monitor memory usage of the RIS (Real-Time Information Server) Data Collector process. The default is n.
Threshold - Maximum memory use for the RIS Data Collector process	Specify the maximum amount of memory that can be used by the RIS Data Collector process before an event is raised. The default is 50000 KB.
Monitor the IP Voice Streaming Media process?	Set to **y** to monitor memory usage of the IP Voice Streaming Media process. The default is n.
Threshold - Maximum memory use for the IP Voice Streaming Media process	Specify the maximum amount of memory that can be used by the IP Voice Streaming Media process before an event is raised. The default is 50000 KB.

19.19 CCM_MemoryHigh

Use this Knowledge Script to monitor the memory that application processes are consuming. This script checks the memory used by each process individually, and the total memory used by all processes. If a process is not found, the script assumes that the process is not running, and reports zero as the memory result.

19.19.1 Resource Object

CCM parent object

19.19.2 Default Schedule

By default, this script runs every five minutes.

19.19.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if threshold is exceeded?	Set to **y** to raise an event if one of the thresholds is exceeded. The default is y.
Collect data?	Set to **y** to collect data about memory usage for graphs and reports. The default is n.
Event severity when threshold is exceeded	Set the severity level, from 1 to 40, to indicate the importance of an event in which a threshold is exceeded. The default is 8.
Monitor the Cisco CallManager process?	Set to **y** to monitor the Cisco CallManager process. The default is y.
Threshold - Maximum memory usage for CallManager process	Specify the maximum memory usage by the CallManager process that can occur before an event is raised. The default is 200000 KB.
Threshold - Maximum memory pool usage for CallManager process	Specify the maximum memory pool usage by the CallManager process that can occur before an event is raised. The default is 5000 KB.
Monitor other Cisco processes?	Set to **y** to monitor other Cisco processes. The default is n.
Threshold - Maximum memory usage for other Cisco processes	Specify the maximum memory usage by other Cisco processes that can occur before an event is raised. The default is 25000 KB.
Threshold - Maximum memory pool use for other Cisco processes	Specify the maximum memory pool usage by other Cisco processes that can occur before an event is raised. The default is 5000 KB.

19.20 CCM_MOHUnavailable

Music on Hold (MOH) resources are provided by software-based MOH servers that register with CallManager. MOH servers are configured through CallManager Administration. Each MOH server is capable of supplying up to 500 Unicast output streams and 204 Multicast streams simultaneously, and can be configured for up to 51 different audio sources.

Use this Knowledge Script to monitor the number of times that an attempt was made to allocate an MOH resource when either every available connection on all MOH servers was active, or when no MOH servers were registered.

19.20.1 Resource Object

CCM parent object

19.20.2 Default Schedule

By default, this script runs every 10 minutes.

19.20.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if threshold is exceeded?	Set to **y** to raise an event if the number of out-of-resource instances exceeds the threshold. The default is y.
Collect data?	Set to **y** to collect data about out-of-resource instances for graphs and reports. The default is n.
Event severity when threshold is exceeded	Set the severity level, from 1 to 40, to indicate the importance of an event in which the number of out-of-resource instances exceeds the threshold. The default is 10.
Threshold - Maximum out-of-resource instances	Specify the maximum number of out-of-resource instances that can occur before an event is raised. The default is 0.

19.21 CCM_PhoneCheck

Use this Knowledge Script to monitor your CallManager for new and missing phones. With each iteration of the job, this script creates a list of the phones registered to the CallManager, and then compares the latest list information with the information from the previous list. You can determine the frequency with which this script runs from the Schedule tab.

NOTE:

- This script does not return information about H.323 devices.
- The list is sorted by the Description, not the Device Name, of the phone that you configured in CallManager.

19.21.1 Resource Object

CCM Call Processor

19.21.2 Default Schedule

By default, this script runs every 15 minutes.

19.21.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Script Options	
Name for current phone list	Provide a name for the current list of new or missing phones. The default is `NQCurrentPhoneList`.
Name for global phone list	Provide a name for the global list of new or missing phones. The default is `NQGlobalPhoneList`.
Monitor New and Missing Phones	
Event Notification	
Raise event if new phones are found?	Select **Yes** to raise an event if new phones are found since the last time you ran the script. The default is Yes.
Event severity when new phones are found	Set the severity level, from 1 to 40, to indicate the importance of an event in which new phones are found. The default is 30.
Raise event if phones are missing?	Select **Yes** to raise an event if any phones are missing since the last time you ran the script. The default is Yes.
Event severity when phones are missing	Set the severity level, from 1 to 40, to indicate the importance of an event in which phones are missing. The default is 15.

19.22 CCM_PhoneInventory

Use this Knowledge Script to take an inventory of phones based on specified search criteria and to write the inventory results to a file. Unless you specify a UNC path, `\\servername\sharename\directoryname\filename`, the results file is written on the CallManager Publisher computer where the NetIQ agent is running.

19.22.1 Monitoring Phone Status

You can determine the status (registered or deregistered) of CallManager phones for active CallManager 4.x clusters and for CallManager 4.x clusters on which failover has occurred. Failover occurs when CallManager status changes from Primary to Backup.

For active CallManager clusters

In this scenario, use the phone deregistration support provided by the CiscoCM_4x_PhoneDeregistrations Knowledge Script from the AppManager for Cisco Unified CallManager module. By using this script, you can determine which phones have deregistered and maintain a history of phone deregistrations in the Cisco CM supplemental database.

AppManager for Cisco Unified CallManager provides limited support for monitoring phone deregistrations on CallManager 4.x clusters. For more information, see the *AppManager for Cisco Unified CallManager Management Guide*.

For CallManagers that have failed over

CallManagers that fail over contain only a list of phones that have registered since failover occurred. They do not provide a list of phones that deregistered as a result of failover. Use the CCM_PhoneInventory Knowledge Script to determine which phones have deregistered. Use the *Monitor for new/missing phone registrations?* parameter to monitor for phone registrations that are missing since the last time this script was run.

To determine whether failover has occurred, use the CCM_RoleStatus or LossOfHardwarePhones Knowledge Script.

19.22.2 Resource Object

CCM Publisher

19.22.3 Default Schedule

By default, this script runs once.

19.22.4 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Script Options	

Parameter	How to Set It
Collect data?	Select **Yes** to collect data about the number of configured and registered phones for reports and graphs. The default is unselected.
CallManager database username	Provide the user login account required to access the CallManager SQL Server database. Leave this field blank to accept the default Cisco login account: `CiscoCCMCDR`. If you changed the default password for `CiscoCCMCDR`, or want to use a different login account, configure the login and password using AppManager Security Manager before running this script. On the SQL tab of Security Manager, provide the IP address or hostname of the CallManager **SQL Server** computer, as well as the **SQL Login Name** and **SQL Login password**.
Monitor for new/missing phone registrations?	Select **Yes** to monitor for phone registrations that are new or missing since the last time this script was run. The default is unselected.
Search Options	
Select by	Choose the type of the selection criteria that you want to use to create the list of phones. • Name (the default) • DirectoryNumber • Description • DevicePool • CallingSearchSpace • Partition • Subnet. If you select this option, you must enter the subnet address in the *Selection criteria* parameter. Use the following syntax: `172.16.10.0/20`. • SubnetFilepath. If you select this option, in the *Selection criteria* parameter, enter the UNC or full path to a file on the agent computer that contains a list of subnet specifications.
Selection criteria	Provide the selection criteria for the phones to be listed. You can specify the actual item or you can specify a pattern by using the * wildcard. For example, to monitor all the phones with device names that begin with SEP, enter `SEP*`. You can enter multiple items by separating each item with a comma. For example: `SEP0009A*,SEP0009B*` The items you enter must be of the same type as the *Select by* parameter. So if *Select by* is **Name**, the items you enter must be device names or patterns. If *Select by* is **Directory Number**, the items you enter must be directory numbers or patterns.
Result File Options	

Parameter	How to Set It
Write details to result file?	Select **Yes** to write the details about each phone to the result file specified in the *Result file name* parameter. The default is Yes. The following details about each phone will be returned in a `.csv` file: • Name • Description • Directory number • Partition (if available) • Model • Device Pool (if available) • Calling Search Space (if available) • Location • IP address (if available) • CallManager node where device is\was registered (if available) • Status • Status Time
Result file name	Provide the full path or a UNC path to a location on the agent computer where the inventory `.csv` file should be written. The default path is `c:\Program Files\NetIQ\Temp\NetIQ_Debug\PhoneInventory.csv`
Write phone registration change details to a second result file?	Select **Yes** to write the details about new or missing registrations to the result file specified in the *Phone registration changes file name* parameter. The default is Yes.
Phone registration changes file name	Provide the full path or a UNC path to a location on the agent computer where the registration changes `.csv` file should be written. The default path is `c:\Program Files\NetIQ\Temp\NetIQ_Debug\PhoneInventoryComparison.csv`
List only phone with status of	Use this parameter to limit the phones listed in the results file to only those whose status is one of the following: • Any (the default) • Not Registered • Registered • Unregistered • Rejected • Unknown **NOTE:** Setting this parameter to a value of **Not Registered** will list those phones with a status of **Unregistered**, **Rejected**, and **Unknown**.
Order by	Select **Name** to display the contents of the results file in order by the phone name. The default is Name. Select **DirectoryNumber** to display the contents of the results file in order by directory numbers.
Threshold	
Threshold type	Select whether you want to monitor for **Percentage** or **Number** thresholds. The default is Percentage.

Parameter	How to Set It
Threshold - Minimum % phones registered	Specify the minimum percentage of phones that must have a status of Registered before an event is raised. The default is 75%.
Threshold - Minimum # phones registered	Specify the minimum number of phones that must have a status of Registered before an event is raised. The default is 0 phones.
Events	
Raise event if threshold is exceeded?	Select **Yes** to raise an event when a threshold is exceeded. The default is Yes.
Raise informational event when inventory completes?	Select **Yes** to raise an informational event when the inventory has completed. The default is Yes.
Event severity when threshold is exceeded	Set the event severity level, from 1 to 40, to indicate the importance of an event in which a threshold is exceeded. The default is 15.
Event severity when failures occur	Set the event severity level, from 1 to 40, to indicate the importance of an event in which a failure occurred, such as an inability to write to the file or access the database. The default is 15.
Event severity when no records found	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the results file returns no data. The default is 30.

19.22.5 Event Messages for CCM_PhoneInventory

The following are common event messages, accompanied by an explanation, a likely cause, and any operator action that may be needed.

PhoneInventory: x Configured and y Registered

Explanation: This message is returned when the inventory completes.

Likely causes: The script ran successfully.

Operator action: No action required.

 # registered phones is low

Explanation: The number of phones in the inventory that have a status of Registered does not meet the threshold.

Likely causes: If one or two phones are unavailable, it probably means that someone has unplugged them from the network. If many phones are unavailable, either there is a network problem or a failover may be in progress.

Operator action: Verify that the phones are plugged into the network and are operational. If many phones are unavailable, check to see whether a failover has occurred. If a failover has occurred, the phones should get re-registered to the backup CallManager and should become available again. If there is a network problem, contact the network administrator.

% registered phones is low

Explanation: The percentage of phones in the inventory that have a status of Registered does not meet the threshold.

Likely causes: If one or two phones are unavailable, it probably means that someone has unplugged them from the network. If many phones are unavailable, either there is a network problem or a failover may be in progress.

Operator action: Verify that the phones are plugged into the network and are operational. If many phones are unavailable, check to see whether a failover has occurred. If a failover has occurred, the

phones should get re-registered to the backup CallManager and should become available again. If there is a network problem, contact the network administrator.

Syntax error: <reason>

Explanation: One or more parameters entered are invalid. See the detailed event message for details about the error.

Likely causes: An invalid parameter or combination of parameters were entered.

Operator action: Fix the invalid parameter and run the script again.

Unable to access result file.

Explanation: The file name entered could not be accessed.

Likely causes: The path is inaccessible from the NetIQ agent, *or* the NetIQ agent does not have the proper permissions to access the file, *or* the file is in use by another process.

Operator action: Verify that the file is not use by another process and the path is accessible from the NetIQ agent. If you are trying to write to a network share, you may need to change the netiqmc service to not run as the LocalSystem account. In most cases, this account does not have the necessary permissions to write to a network drive.

Error encountered getting password.

Explanation: A database user name was entered and errors were encountered while trying to retrieve the password for this user name from the NetIQ AppManager Security Manager.

Likely causes: In most cases, this message Indicates the user name has not been properly entered in AppManager Security Manager.

Operator action: Verify that the user name has been properly entered in AppManager Security Manager.

Incorrect managed object version.

Explanation: The NetIQ CallManager managed object (`qccma4.dll`) is not at the correct level to run this script.

Likely causes: The NetIQ agent on the CallManager server being monitored is not at the latest level.

Operator action: Upgrade the NetIQ agent to the latest level.

Database operation failed.

Explanation: An error was encountered executing a SQL query.

Likely causes: In most cases this message Indicates the NetIQ agent does not have the proper authority to execute the query. Another reason could be that the SQL query timed out because the SQL server was too busy. The detailed message should contain the reason that the SQL query failed.

Operator action: If a timeout occurred, try the query at a time when the SQL server is not so busy. If using a user name and password, verify that the user name has access to the CallManager configuration database. If using Windows authentication (blank user name), verify that the `netiqmc` process is running with the correct permissions to access the database.

Internal error encountered.

Explanation: An unrecoverable error was encountered. See the detailed event message for details about the error.

Likely causes: In most cases this message Indicates a COM interface was not available, either because the COM object has not been installed or is not registered.

Operator action: Verify that the NetIQ CallManager managed object (`qccma4.dll`) is installed and registered on the CallManager server.

19.23 CCM_PRIChannels

Use this Knowledge Script to monitor the number of active and in-service PRI (primary rate interface) channels for this CallManager. This script raises an event if a monitored value exceeds or falls below the threshold you set.

The ports or channels you monitor can be on one or more MGCP gateways.

19.23.1 Resource Object

CCM Call Processor

19.23.2 Default Schedule

By default, this script runs every five minutes.

19.23.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if threshold is breached?	Set to **y** to raise an event if either threshold is breached. The default is y.
Collect data?	Set to **y** to collect data about PRI channels for reports and graphs. The default is n.
Suppress event when Role is set to Backup?	Set to **y** to suppress event generation on CallManager resources whose role is set to "backup." By suppressing event generation, you can run a script on all CallManager resources without raising an event on a resource that is not actively handling calls. The default is y.
Event severity when threshold is breached	Set the event severity level, from 1 to 40, to indicate the importance of an event in which a threshold is breached. The default is 15.
Threshold - Maximum active PRI channels	Specify the maximum number of PRI channels that can be active before an event is raised. The default is 10 channels.
Threshold - Minimum PRI spans in service	Specify the minimum number of PRI spans that can be in service before an event is raised. The default is 0 channels.

19.24 CCM_Replication

Use this Knowledge Script to query for failed actions in the distribution, snapshot, and logreader history tables of the replication agents on the CallManager Publisher.

Replication allows you to keep copies of the same data on multiple sites. The Publisher is the source of the replication. The Publisher defines an article for each table or other database object to be used as a replication source. One or more related articles from the same database are organized into a *publication*. A publication is a convenient way to group together related data that you want to replicate.

The Subscriber receives the replication data from the Publisher. The Subscriber defines a *subscription* to a particular publication. The subscription specifies when the Subscriber receives the publication from the Publisher, and maps the articles to tables and other database objects in the Subscriber.

Cisco CallManager uses two types of replication:

19.24.1 Snapshot Replication

Snapshot replication copies data or database objects exactly as they exist at the time of replication. Snapshot publications are typically defined to occur on a scheduled basis, however, the publication is sent to the Subscriber only if the latest publication reflects a difference from the previous publication. The Subscriber contains copies of the published articles, as they existed at the time of the last snapshot. Snapshot replication is typically used when the source data is relatively static, or when the Subscribers can be slightly out of date, or if the amount of data to replicate is small.

19.24.2 Transactional Replication

In a transactional replication, Subscribers are first synchronized with the Publisher (typically by using a snapshot), and then, as the publication data is modified, the transactions are captured and sent to the Subscribers. Transactional integrity is maintained across the Subscribers by having all modifications made at the Publisher and then replicated to the Subscribers. Transactional replication is typically used when data must be replicated as it is modified, you must preserve the transactions, and the Publishers and Subscribers are reliably and frequently connected through the network.

Database replication is accomplished through the use of several replication agents, processes that perform specific replication tasks. CallManager uses three replication agents: snapshot agent, log reader agent, and distribution agent.

To begin transactional replication, the Subscriber needs an initial snapshot of the entire database. The *snapshot agent* on the Publisher collects the information for database snapshots. The snapshot agents takes a snapshot only if a Subscriber becomes out of sync with the Publisher, or if the subscription was re-initialized. If the Subscriber does not need a snapshot, the snapshot agent does nothing when it runs on its schedule.

The *log reader agent* is responsible for moving any changes made to the Publisher database to the distribution database. For each Subscriber, a *distribution agent* is responsible for taking information from the distribution database and moving it to the appropriate Subscriber.

NOTE: This script assumes that the distribution database on the CallManager Publisher has not been renamed to something other than "distribution," which is the name assigned when CallManager installed the database.

19.24.3 Resource Object

CCM Publisher

19.24.4 Default Schedule

By default, this script runs every hour.

19.24.5 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
On first run, hours to go back	Specify the number of hours of previous replication agent history to check the first time you run this script. For instance, if you enter 24, the first time you run this script it will check actions made by the agents in the last 24 hours. On subsequent runs, it will check only agent actions that have occurred during the interval. The default is 1 hour. **NOTE:** Using a high "hours to go back" time may cause this script to be CPU-intensive on its first run, depending on the number of database entries being retrieved from the server.
Distribution database username	Provide the user login account required to access the CallManager SQL Server database. Leave this field blank to accept the default Cisco login account: `CiscoCCMCDR`. If you changed the default password for `CiscoCCMCDR`, or want to use a different login account, configure the login and password using AppManager Security Manager before running this script. On the SQL tab of Security Manager, provide the IP address or hostname of the CallManager **SQL Server** computer, as well as the **SQL Login Name** and **SQL Login password**.
Threshold - Maximum failed actions by any agent	Specify the maximum number of failed actions that can have occurred during the interval for any of the agents. If the number of failed actions is greater than the threshold that you set, an event is raised. The default is 0.
Raise informational event with agent history?	Set to **y** to raise an informational event containing the last 10 actions that occurred during the interval for each replication agent. The default is y.
Raise informational event if snapshot generated?	Set to **y** to raise an informational event if, during the interval, the snapshot agent on the CallManager Publisher has generated any replication snapshots. The default is y.
Event severity when threshold is exceeded	Set the severity level, from 1 to 40, to indicate the importance of an event in which the threshold has been exceeded. The default is 5.
Event severity for informational messages	Set the severity level, from 1 to 40, to indicate the importance of an informational event message. The default is 30.

Parameter	How to Set It
Event format	Select the format in which you want to receive the informational event: CSV, XML, or both. If you select **Both**, the CSV (comma separated value) event is collapsed under the XML event. To access the CSV event, turn off **Collapse duplicate events into a single event** on the Advanced tab before running this script. **Notes** • Events formatted in XML are not forwarded to an Action script (if you selected to initiate an Action script if this script generates an event). If you select **Both**, two events are generated: one in CSV format, which is forwarded to an Action script, and one in XML format. • Error messages are formatted in plain text — this parameter does not apply to error messages.

19.24.6 Event Messages for CCM_Replication

Following are common event messages, accompanied by an explanation, a likely cause, and any operator action that may be needed.

 # failed replications actions high.

Explanation: The number of failed actions in one or more of the replication agent history tables exceeded the threshold.

Likely cause: One or more replication actions have failed.

Operator action: Check the detailed message, which will contain a list of the last 25 failed actions, as well as the name of the replication agent that has the failures. Forward the information to your database administrator.

Replication history.

Explanation: This is an informational message containing the last 25 actions for all the replication agents. See the detailed event message for the data.

Likely cause: This is a normal event message when *Generate informational event with agent history?* is set to "y."

Operator action: No action is required.

Replication snapshot(s) generated.

Explanation: This is an informational message created when a replication snapshot has been generated on the CallManager Publisher during the interval. See the detailed event message for information about the snapshot.

Likely cause: This is a normal event message when *Generate informational event if a replication snapshot was generated?* is set to "y."

Operator action: No action is required.

Error encountered getting password.

Explanation: A database user name was entered and errors were encountered while trying to retrieve the password for this user name from the AppManager Security Manager.

Likely cause: In most cases, this message Indicates the user name was not properly entered in the AppManager Security Manager.

Operator action: Verify that the user name has been properly entered in the AppManager Security Manager.

Incorrect managed object version.

Explanation: The AppManager CallManager managed object (`qccma4.dll`) is not at the correct level to run this script.

Likely cause: The AppManager agent on the CallManager server being monitored is not version 6.0.

Operator action: Upgrade the AppManager agent to Version 6.0 or later.

No CallManager replication agents found.

Explanation: No CallManager replication agents (snapshot, log reader, or distribution) were found when querying the distribution database on the Publisher.

Likely cause: In most cases, this message occurs when the distribution database has been renamed to something other than "distribution."

Operator action: Verify that the distribution database has not been renamed.

Database operation failed.

Explanation: An error was encountered while executing a SQL query.

Likely cause: In most cases, this message Indicates the AppManager agent does not have the proper authority to execute the query. The detailed message should contain the reason for the failure of the SQL query.

Operator action: If using a user name and password, verify that the user name has access to the distribution database. If using Windows authentication (blank user name), verify that the netiqmc process is running with the correct permissions to access the distribution database.

Internal error encountered.

Explanation: An unrecoverable error was encountered. See the detailed event message for details about the error.

Likely cause: In most cases, this message Indicates a COM interface was not available, because either the COM object is not installed or is not registered.

Operator action: Verify that the AppManager CallManager managed object (`qccma4.dll`) is installed and registered on the CallManager server.

19.25 CCM_ResetDevice

Use this Knowledge Script to reset one or more devices in order for the devices to pick up new default firmware. For example, if a new firmware load is placed on the TFTP servers, all devices using this firmware need to be reset.

To avoid resetting all the devices during peak times, schedule this script to run when the system is not busy.

This script initiates only the Reset or Restart command. It does *not* check on the success or failure of the command.

If a device is not registered with Cisco CallManager, you cannot reset or restart it. Resetting a gateway/trunk drops any in-progress calls that are using the gateway/trunk. Restarting a gateway tries to preserve the in-progress calls that are using the gateway. Other devices wait until calls are complete before restarting or resetting. Resetting or restarting an H.323 device does not physically reset or restart the device, but only re-initializes the configuration loaded by Cisco CallManager.

NOTE: Only an AppManager administrator should run this script.

19.25.1 Resource Object

CCM Publisher

19.25.2 Default Schedule

By default, this script runs once.

19.25.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Select reset type	Select the type of reset that you want to initiate: **Reset** or **Restart**. This parameter is valid only for the Directory Number, Device Name, and Device Description patterns. The reset type is *always* Reset for the Device Type and Device Pool parameters. A Restart resets the device without shutting it down. A Reset shuts down the device and then restarts it. The default is Reset.
Directory Number pattern	Specify the directory number pattern of the devices that you want to reset. You can specify a group of directory numbers by using the % wildcard. For example, to reset all the devices with directory numbers that begin with "31," enter `31%`. The reset/restart is performed only if the pattern results in 100 or fewer devices being selected.

Parameter	How to Set It
Device Name pattern	Specify the device name pattern of the devices that you want to reset. You can specify a group of device names by using the % wildcard. For example, to reset all the devices with device names that begin with "SEP," enter `SEP%`. The reset/restart is performed only if the pattern results in 100 or fewer devices being selected.
Device Description pattern	Specify the device description pattern of the devices that you want to reset. You can specify a group of device descriptions by using the % wildcard. For example, to reset all the devices with device descriptions that begin with "Auto," enter `Auto%`. The reset/restart is performed only if the pattern results in 100 or fewer devices being selected.
Select device type	Select the type of the device that you want to reset. All devices of that type will be reset. The default is None. Valid device types are indicated as follows: • AllPhones, which resets devices of the following types: Cisco 12 S, Cisco 12 SP, Cisco 12 SP+, Cisco 30 SP+, Cisco 30 VIP, Cisco IP Phone 7905, Cisco IP Phone 7910, Cisco IP Phone 7935, Cisco IP Phone 7940, Cisco IP Phone 7960, Cisco ATA 186, Cisco VGC Phone, Cisco VGC Virtual Phone, and H.323 Phone. • All79xxPhones, which resets devices of the following types: Cisco IP Phone 7905, Cisco IP Phone 7910, Cisco IP Phone 7935, Cisco IP Phone 7940, and Cisco IP Phone 7960. • Analog Access • Analog Access WS-X6624 • Cisco 12 S, 12 SP, and 12 SP+ • Cisco 30 SP+ and 30 VIP • Cisco IP Phone 7905, 7910, 7935, 7940, and 7960 • Cisco ATA 186 • Cisco VGC Phone and VGC Virtual Phone • Conference Bridge and Conference Bridge WS-X6608 • Digital Access, Digital Access WS-X6608, and Digital Access+ • H.323 Phone • Load Simulator • MTP and MTP WS-X6608 • MGCP Station and MGCP Trunk • VGC Gateway • 14-Button Line Expansion Module
Device pool name	Specify the name of the device pool that you want to reset. All devices in the pool will be reset.
Event severity when reset succeeds	Set the severity level of the event, from 1 to 40, to indicate the importance of an event in which the reset succeeds. The default is 25. For more information, see "Event Messages for CCM_ResetDevice" on page 884.
Event severity when warnings occur	Set the severity level of the event, from 1 to 40, to indicate the importance of the event in which warnings occurred. The default is 15.
Event severity when errors occur	Set the severity level of the event, from 1 to 40, to indicate the importance of the event in which errors occurred. The default is 5.

19.25.4 Event Messages for CCM_ResetDevice

Following are three common event messages, accompanied by an explanation, a likely cause, and any operator action that may be needed.

Reset issued successfully.

Explanation: The reset command was issued successfully for all selected devices. See the detailed event message for the number of devices for which the reset was issued.

Likely cause: Normal message.

Operator action: None.

Reset issued with warnings.

Explanation: Warnings were encountered while issuing the reset command for one or more of the selected devices. See the detailed event message for more information.

Likely causes: In most cases, this message Indicates one or more of the selections resulted in no devices being found to reset. Another likely cause is that too many devices were selected for reset.

Operator action: No action is required if there are no devices associated with the command. If too many devices were selected, then, if possible, use the device type or device pool parameter.

Reset issued with errors.

Explanation: Errors were encountered while issuing the reset command for one or more of the selected devices. See the detailed event message for details about the error.

Likely cause: In most cases, this message Indicates a COM interface was not available, either because the COM object has not been installed or because the COM object is not registered.

Operator action: Verify that the `dblx.dll` is installed and registered on the CallManager computer.

19.26 CCM_RestartService

Use this Knowledge Script to schedule a CallManager service to stop and then restart after a specified interval. This script raises an event when stop fails or succeeds, when restart fails or succeeds, and when the status of a service is unavailable. In addition, this script generates data streams for service availability.

19.26.1 Resource Object

CCM Service folder

19.26.2 Default Schedule

By default, this script runs every hour.

19.26.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Collect data?	Set to **y** to collect data about CallManager services for graphs and reports. The default is n.
Wait N seconds before restarting	Set the number of seconds that you want to wait before restarting a stopped CallManager service. The default is 5 seconds.
Event severity when stop fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the stop failed. The default is 5.
Event severity when restart fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the restart failed. The default is 5.
Event severity when status of service is unavailable	Set the severity level, from 1 to 40, to indicate the importance of an event in which the status of the service is unavailable. The default is 15.
Event severity when stop succeeds	Set the severity level, from 1 to 40, to indicate the importance of an event in which the stop succeeds. The default is 25.
Event severity when restart succeeds	Set the severity level, from 1 to 40, to indicate the importance of an event in which the restart succeeds. The default is 25.
Event severity when service is paused	Set the severity level, from 1 to 40, to indicate the importance of an event in which the service is paused. The default is 20. Some services enter a paused state when the system is low on CPU or memory resources. Enter **0** when you do not want to raise an event for this situation.
Restart Cisco CallManager service?	Set to **y** to restart Cisco CallManager. The default is y.
Restart Cisco Database Layer Monitor service?	Set to **y** to restart Cisco Database Layer Monitor. The default is y.
Restart Cisco IP Voice Media Streaming App service?	Set to **y** to restart Cisco IP Voice Media Streaming App. The default is n.

Parameter	How to Set It
Restart Cisco Messaging Interface service?	Set to **y** to restart Cisco Messaging Interface. The default is n.
Restart Cisco SNMP Data Collector service?	Set to **y** to restart Cisco SNMP Data Collector. The default is n.
Restart Cisco Telephony Call Dispatcher service?	Set to **y** to restart Cisco Telephony Call Dispatcher. The default is n.
Restart Cisco TFTP service?	Set to **y** to restart Cisco TFTP. The default is n.
Restart Cisco SNMP Data Collector service? (For CallManager 3.0 only)	Set to **y** to restart Cisco SNMP Data Collector service. The default is n.
Restart Cisco CTI Manager service? (for CallManager 3.1 only)	Set to **y** to restart Cisco CTI Manager. The default is n.
Restart Cisco Extension Mobility Logout service? (for CallManager 3.1 only)	Set to **y** to restart Cisco Extension Mobility Logout. The default is n.
Restart Cisco MOH Audio Translator service? (for CallManager 3.1 only)	Set to **y** to restart Cisco MOH Audio Translator. The default is n.
Restart Cisco RIS Data Collector service?	Set to **y** to restart Cisco RIS Data Collector. The default is n.

19.27 CCM_RoleStatus

Use this Knowledge Script to determine whether a CallManager's status is Primary or Backup. You can choose to raise an event for status transitions. A Backup is defined as any CallManager with no registered hardware or software phones.

In the event of a failover from a Primary CallManager to a Backup CallManager, you can set the **Actions** tab of this script to run Action_RunDiscoveryCiscoCallMgr. The Action script will discover CallManager resources on the backup device and, if you have configured a monitoring policy to do so, any jobs that are running on the Primary device will be transferred to the Backup CallManager.

This script is a member of a Recommended Knowledge Script Group. For more information, see "Recommended Knowledge Script Groups" on page 1057.

You can also use this script to monitor phone status. For more information, see CCM_PhoneInventory.

19.27.1 Resource Object

CCM Call Processor

19.27.2 Default Schedule

By default, this script runs every five minutes.

19.27.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event when Backup changes to Primary?	Set to **y** to raise an event when the CallManager status changes from Backup to Primary. The default is y.
Event severity when Backup changes to Primary	Set the event severity level, from 1 to 40,to indicate the importance of an event in which the status changes from Backup to Primary. The default is 15.
Raise event when Primary changes to Backup?	Set to **y** to raise an event when the CallManager status changes from Primary to Backup. The default is y.
Event severity when Primary changes to Backup	Set the event severity level, from 1 to 40,to indicate the importance of an event in which the status changes from Primary to Backup. The default is 15.
Collect data?	Set to **y** to collect data for reports and graphs. A Primary returns a value of 100; a Backup returns a value of 0. The default is n.

19.28 CCM_SecureWebPageCheck

Use this Knowledge Script to monitor accessibility to the `ccmadmin` and `ccmuser` secure Web pages, and raise an event if the Web pages cannot be accessed. This script can collect data about the availability of the Web pages and round-trip connection time. If a URL is not reachable, the detail message records the reason, such as the format of the request was invalid or the server name was not found. If the Web pages cannot be accessed, you can arrange for this script to restart the IIS server and sites that are down.

NOTE: This script is supported for Cisco CallManager version 4.1 or later. If you are running an earlier version, use CCM_WebPageCheck.

19.28.1 Resource Objects

CCM IIS Server

CCM IIS W3 SRV

CCM IIS Web Inst

19.28.2 Default Schedule

By default, this script runs every 30 minutes.

19.28.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if Web page is inaccessible?	Set to **y** to raise an event if the Web page cannot be accessed. The default is y.
Collect data for up/down URL?	Set to **y** to collect data about the up and down status of the URL. If set to y, the script returns a value of 100 if the connection is up and a value of 0 if the connection is down. The default is y.
Collect data for round-trip time?	Set to **y** to collect data for charts and reports. If enabled, data collection returns information about the round-trip connection time (in milliseconds). The default is n.
Monitor ccmadmin?	Set to **y** to monitor the ccmadmin Web page. The default is y.
Monitor ccmuser?	Set to **y** to monitor the ccmuser Web page. The default is y.
Username for ccmadmin	Enter the user name to use when logging on to ccmadmin. If a user name is not required, you can leave this field blank. For more information about the user name, see "CCMAdmin User Name and Password Configuration" on page 890.

Parameter	How to Set It
Treat Access Denied errors as "Up"?	When no password or user name is specified for ccmadmin, the URL check for ccmadmin will produce an "access denied" error. However, because the script determines whether the Web page is available, you may want the user name/password prompt to appear (to avoid exposing the admin password). Therefore, if a user name/password is specified (i.e., the user name and password are *not* blank), set this parameter to n. If no user name/password is specified (i.e., if the user name or password is blank), set this parameter to y. The default is y.
Number of times to retry after a fail	Specify the number of times to retry the connection. The default is 3 times.
Amount of time to wait between retries	Specify the number of seconds to wait for a connection before timing out and returning an error. The default is 0 seconds.
Event severity when Web page is inaccessible	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 8.
Monitor IIS server and site(s)?	Set to **y** to monitor the IIS server and associated sites. The default is y.
Auto-start monitored server and site(s)?	Set to **y** to automatically restart down IIS servers and sites. The default is y.
Event severity when auto-start fails	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the server is down and AppManager cannot restart it. The default is 5.
Event severity when auto-start succeeds	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the server was down and AppManager successfully restarted it. The default is 25.
Event severity when auto-start is set to "n"	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the server is down and AppManager has been set not to restart the service. The default is 18.

19.28.4 CCMAdmin User Name and Password Configuration

If you require a user name and password for access to your `ccmadmin` Web page, configure that information into AppManager Security Manager. Then, when you run CCM_SecureWebPageCheck or CCM_WebPageCheck, the script will have authority to access the Web page.

On the Custom tab in AppManager Security Manager, complete the following fields:

Field	Description
Label	CCMADMIN
Sub-label	User name required for accessing the ccmadmin Web page
Value 1	Password required for accessing the ccmadmin Web page
Extended application support	Encrypts the user name and password in Security Manager. Do not leave this option unselected.

19.29 CCM_SystemPerformance

Use this Knowledge Script to monitor Cisco CallManager for call throttling, signals in queue, and severe and warning call-throttling states. Call throttling allows administrators to define CallManager performance parameters to limit the number of incoming calls from phones, IOS gateways, MGCP gateways, and MGCP PRI gateways. The CallManager code red and code yellow call-throttling states map to AppManager severe and warning level states, respectively.

NOTE: This script is supported only for CallManager versions 3.3(4) and later.

19.29.1 Resource Object

CCM parent object

19.29.2 Default Schedule

By default, this script runs every five minutes.

19.29.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Monitor Call Throttling	
Event Notification	
Raised event if threshold is exceeded?	Select **Yes** to raise an event if either or both of the call throttling thresholds are exceeded. The default is Yes.
Threshold - Maximum rejected calls	Specify the maximum number of calls that can be rejected due to call throttling before an event is raised. The default is 10 calls.
Threshold - Maximum throttled skinny devices	Specify the maximum number of skinny devices that can be throttled before an event is raised. The default is 10 devices.
Event severity when rejected calls exceed the threshold	Set the severity level, from 1 to 40, to reflect the importance of an event in which the number of rejected calls exceeds the threshold that you set. The default is 5.
Event severity when throttled skinny devices exceed the threshold	Set the severity level, from 1 to 40, to reflect the importance of an event in which the number of throttled skinny devices exceeds the threshold that you set. The default is 5.
Raise event if severe call-throttling state entered?	Select **Yes** to raise an event if call throttling enters a severe (Code Red) state. The default is Yes.
Event severity when severe state entered	Set the severity level, from 1 to 40, to reflect the importance of an event in which call throttling has entered a severe state. The default is 5.
Raise event if warning call-throttling state entered?	Select **Yes** to raise an event if call throttling enters a warning (Code Yellow) state. The default is unselected.

Parameter	How to Set It
Event severity when warning state entered	Set the severity level, from 1 to 40, to reflect the importance of an event in which call throttling has entered a warning state. The default is 15.
Data Collection	
Collect data for call throttling?	Select **Yes** to collect data about calls rejected due to call throttling and about throttled skinny devices. The default is unselected.
Monitor Signals in Queue	
Event Notification	
Raise event if threshold is exceeded?	Select **Yes** to raise an event if either or both of the signal thresholds are exceeded. The default is Yes.
Threshold - Maximum high-priority signals in queue	Specify the maximum number of high-priority signals that can be in queue before an event is raised. The default is 500.
Threshold - Maximum normal-priority signals in queue	Specify the maximum number of normal-priority signals that can be in queue before an event is raised. The default is 1000.
Event severity when high-priority signals exceed the threshold	Set the severity level, from 1 to 40, to reflect the importance of an event in which the number of high-priority signals in queue exceeds the threshold that you set. The default is 5.
Event severity when normal-priority signals exceed the threshold	Set the severity level, from 1 to 40, to reflect the importance of an event in which the number of normal-priority signals in queue exceeds the threshold that you set. The default is 5.
Data Collection	
Collect data for signals in queue?	Select **Yes** to collect data about high and normal priority queue signals. The default is unselected.

19.30 CCM_SystemUsage

Use this Knowledge Script to monitor CPU and physical memory usage for the Cisco CallManager process, and total CPU and physical memory usage for the CallManager. If any threshold is exceeded, an event is raised. This script collects data about percentage of CPU and physical memory used by CallManager and percentage of CPU and physical memory used by the entire device. When monitoring a device without the CallManager process (such as a standalone Publisher) only the percentage of CPU and physical memory used by the device are collected. To make the most of the data collected by this script, run Report_SystemUsage.

This script is a member of a Recommended Knowledge Script Group. For more information, see "Recommended Knowledge Script Groups" on page 1057.

TIP: On the Advanced tab, set the *Raise event if event condition occurs* parameter to **3** times within **3** job iterations to prevent the raising of events during peak usage.

19.30.1 Resource Object

CCM parent object

19.30.2 Default Schedule

By default, this script runs every five minutes.

19.30.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if threshold is exceeded?	Set to **y** to raise an event if a threshold is exceeded. The default is y.
Collect data?	Set to **y** to collect data about CPU and memory usage or reports and graphs. The default is y.
Event severity when threshold is exceeded	Set the event severity level, from 1 to 40,to indicate the importance of an event in which a threshold is exceeded. The default is 10.
Threshold - Maximum CallManager CPU usage	Specify the maximum percentage of CallManager CPU resources that can be used before an event is raised. The default is 65%.
Threshold - Maximum total CPU usage	Specify the maximum percentage of system CPU resources that can be used before an event is raised. The default is 80%.
Threshold - Maximum CallManager memory usage	Specify the maximum amount of CallManager memory resources that can be used before an event is raised. The default is 65%.
Threshold - Maximum total memory usage	Specify the maximum percentage of system memory resources that can be used before an event is raised. The default is 80%.

19.31 CCM_T1Channels

Use this Knowledge Script to monitor the number of active and in-service T1-CAS (channel associated signaling) channels for this CallManager. This script raises an event if a monitored value exceeds or falls below the threshold you set.

The ports or channels you monitor can be on one or more MGCP gateways.

19.31.1 Resource Object

CCM Call Processor

19.31.2 Default Schedule

By default, this script runs every five minutes.

19.31.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if threshold is breached?	Set to **y** to raise an event if either threshold is breached. The default is y.
Collect data?	Set to **y** to collect data about T1-CAS channels for reports and graphs. The default is n.
Suppress event when Role is set to Backup?	Set to **y** to suppress event generation on CallManager resources whose role is set to "backup." By suppressing event generation, you can run a script on all CallManager resources without raising an event on a resource that is not actively handling calls. The default is y.
Event severity when threshold is breached	Set the event severity level, from 1 to 40, to indicate the importance of an event in which a threshold is exceeded. The default is 15.
Threshold - Maximum active T1-CAS channels	Specify the maximum number of T1-CAS channels that can be active before an event is raised. The default is 10 channels.
Threshold - Minimum T1-CAS spans in service	Specify the minimum number of T1-CAS spans that can be in service before an event is raised. The default is 0 channels.

19.32 CCM_WebPageCheck

Use this Knowledge Script to monitor accessibility to the `ccmadmin` and `ccmuser` Web pages and raise an event if the Web pages cannot be accessed. This script can collect data about the availability of the Web pages and round-trip connection time. If a URL is not reachable, the detail message records the reason (for example, because the format of the request was invalid or the server name was not found). If the Web pages cannot be accessed, you can arrange for this script to restart the IIS server and sites that are down.

This script is a member of a Recommended Knowledge Script Group. For more information, see "Recommended Knowledge Script Groups" on page 1057.

NOTE: This script is not supported for Cisco CallManager versions 4.1 and later. If you are running 4.1 or later, use CCM_SecureWebPageCheck.

19.32.1 Resource Objects

CCM IIS Server

CCM IIS W3SRV

CCM IIS WebInst

19.32.2 Default Schedule

By default, this script runs every 30 minutes.

19.32.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if Web page is inaccessible?	Set to **y** to raise an event if either Web page is inaccessible. The default is y.
Collect data for up/down URL?	Set to **y** to collect data about the up and down status of the URL. If set to y, the script returns a value of 100 if the connection is up and a value of 0 if the connection is down. The default is y.
Collect data for round-trip time?	Set to **y** to collect information about the round-trip connection time (in seconds). The default is n.
Monitor ccmadmin?	Set to **y** to monitor ccmadmin. The default is y.
Monitor ccmuser?	Set to **y** to monitor ccmuser. The default is y.
Username for ccmadmin	Enter the user name to use when logging on to ccmadmin. If a user name is not required, you can leave this field blank. For more information about the user name, see "CCMAdmin User Name and Password Configuration" on page 890. **NOTE:** If you installed Cisco CallManager MLA (multi-level administration), this script will only verify that the ccmadmin Web page is present. It will not log in. Therefore, if you have MLA, there is no need to enter the user name.

Parameter	How to Set It
Treat Access Denied errors as "Up"?	When no password or user name is specified for ccmadmin, the URL check for ccmadmin will produce an "access denied" error. However, because the script determines whether the Web page is available, you may want the user name/password prompt to appear, to avoid exposing the admin password. Therefore, if the user name and password are not blank, set this parameter to n. If the user name or password is blank, set this parameter to y. The default is y.
Number of times to retry after a fail	Specify the number of times to retry the connection. The default is 3 times.
Amount of time to wait between retries	Specify the number of seconds to wait for a connection before timing out and returning an error. The default is 0 seconds.
Event severity when Web page is inaccessible	Set the event severity level, from 1 to 40,to indicate the importance of an event in which a Web page is inaccessible. The default is 8.
Monitor IIS server and site(s)?	Set to **y** to monitor the IIS server and associated sites. The default is y.
Auto-start monitored server and site(s)?	Set to **y** to automatically restart down IIS servers and sites. The default is y.
Event severity when auto-start fails	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the server is down and AppManager cannot restart it. The default is 5.
Event severity when auto-start succeeds	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the server was down and AppManager successfully restarted it. The default is 25.
Event severity when auto-start is set to "n"	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the server is down and AppManager has not been set to restart the service. The default is 18.

19.33 CDRQuery

Use this Knowledge Script to query the CDR (Call Detail Records) table on the CallManager Publisher. The purpose of this script is twofold:

- Monitoring. In monitoring mode, this script checks the CDR tables at each specified interval for new records that match your query. In the first iteration of the job, this script finds the last record in the CDR table and checks back one interval from there. In subsequent iterations, this script checks for new records that match the query in each interval.
- Diagnostic. In diagnostic mode, this script runs once, and checks the CDR tables for calls whose disconnect time is within the range you select in the *Select call disconnect time range* parameter. To run this script in diagnostic mode, select Run once on the Schedule tab.

19.33.1 Resource Object

CCM Publisher

19.33.2 Default Schedule

By default, this script runs once.

19.33.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Options	
CDR database username	Provide the user login account required to access the CallManager SQL Server database. Leave this field blank to accept the default Cisco login account: `CiscoCCMCDR`. If you changed the default password for `CiscoCCMCDR`, or want to use a different login account, configure the login and password using AppManager Security Manager before running this script. On the SQL tab of Security Manager, provide the IP address or hostname of the CallManager **SQL Server** computer, as well as the **SQL Login Name** and **SQL Login password**.

Parameter	How to Set It
Select event format	Select the format in which you want to receive the informational event: CSV, XML, or Both. The default is XML. • Select **CSV** (comma-separated value) to format an event message that can be forwarded to an Action script that is triggered by the event (if you have selected to initiate an Action script when an event is raised). • Select **XML** to format an event message that is not forwarded to an Action script. • Select **Both** to generate two event messages: one in CSV format, which is forwarded to an Action script, and one in XML format. If you select **Both**, the CSV event is collapsed under the XML event; it is not displayed in the Operator Console. To access the CSV event, turn off "Collapse duplicate events into a single event" on the Advanced tab before running this script. **NOTE:** Error messages are formatted in plain text — this parameter does not apply to error messages.

Parameter	How to Set It
Columns to return	Select the columns that you want returned from the query: All, Basic, or Minimal. The default is Basic. Choose All to return all columns in the CDR table. Different versions of CallManager contain different columns in the CDR tables; you should check your CallManager documentation to see which columns you have. Choose Basic to return the following columns: • origDeviceName • origIpAddr • callingPartyNumber • origMediaCap_payloadCapability • destDeviceName • destIpAddr • originalCalledPartyNumber • finalCalledPartyNumber • destMediaCap_payloadCapability • dateTimeOrigination • dateTimeConnect • dateTimeDisconnect • duration • originalCalledPartyNumberPartition • callingPartyNumberPartition • finalCalledPartyNumberPartition • origCause_value • destCause_value Choose Minimal to return the following columns: • origDeviceName • origIpAddr • callingPartyNumber • destDeviceName • destIpAddr • originalCalledPartyNumber • finalCalledPartyNumber • dataTimeConnect • dataTimeDisconnect • duration
Collect data?	Set to **y** to collect data for graphs and charts. This script collects one data stream for the number of records found. The default is n.
Threshold	
Threshold - Maximum matching records	Specify how many records must match the specified query before an event is raised. The default is 0, which means that an event is raised if at least one record matches the query.
Query Filters	

Parameter	How to Set It
Minimum duration	Set this parameter to filter out records whose call duration is less than the specified value. Accept the default of **0** if you do not want to filter for minimum call duration.
Maximum duration	Set this parameter to filter out records whose call duration is less than or equal to the specified value. Accept the default of **0** if you do not want to filter for maximum call duration.
Calling directory number	Set this parameter to the number of the calling directory that you want to find in the CDRs. Wildcard characters are acceptable. Leave this parameter blank to search for any calling directory number.
Directory number connector	Set this parameter ONLY if you specify both a *Calling directory number* and a *Called directory number*. Your selection indicates how the script will connect the two parameters: AND or OR. The default is AND.
Called directory number	Set this parameter to the number of the called directory that you want to find in the CDRs. Wildcard characters are acceptable. Leave this parameter blank to search for any called directory number.
Originating device name	Set this parameter to query for those calls whose originating device name matches the specified value. Wildcard characters are acceptable. Leave this parameter blank to search for any originating device name.
Device name connector	Set this parameter ONLY if you specify both an *Originating device name* and a *Destination device name*. Your selection indicates how the script will connect the two parameters: AND or OR. The default is AND.
Destination device name	Set this parameter to query for those calls whose destination device name matches the specified value. Wildcard characters are acceptable. Leave this parameter blank to search for any destination device name.
Events	
Raise event if threshold is exceeded?	Set to **y** to raise an event if the matching records threshold is exceeded. The default is y.
Event severity when threshold is exceeded	Set the severity level, from 1 to 40, to indicate the importance of an event in which the threshold is exceeded. The default is 25.
Event severity when no records are found	Set the severity level, from 1 to 40, to indicate the importance of an event in which the script finds no records in the CDR. Accept the default of **0** if you do not want to raise an event for this situation.
Custom event message	Provide a custom message for the event, such as "Calls to 911" or "Calls exceeding 30 minutes." The default message is "# of records exceeded the threshold."
Diagnostics	
Select call disconnect time range	Select a Specific or Sliding date/time range for which the query should search for data. The default time range is fixed at 24 hours. Note This parameter is valid only when you select Run once on the Schedule tab.

19.34 CiscoBackupStatus

Use this Knowledge Script to monitor the Cisco IP Telephony Applications Backup Utility (`stiBack.exe`) program or the Cisco BARS (Backup and Restore System) program. This script verifies that the corresponding backup service is running and restarts the service if you choose. It reads the backup log to check the status of the previous backup. This script raises an event if the previous backup failed and can raise an event for successful backups.

This script is a member of a Recommended Knowledge Script Group. For more information, see "Recommended Knowledge Script Groups" on page 1057.

19.34.1 Resource Object

CCM Backup Utility

19.34.2 Default Schedule

By default, this script runs every two hours.

19.34.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Auto-start backup service?	Select **Yes** to automatically restart stiBack.exe or BARS if it is down. The default is Yes.
Event severity when auto-start fails	Set the event severity level, from 1 to 40, to reflect the importance of an event in which the service is down and AppManager cannot restart it. The default is 5.
Event severity when auto-start succeeds	Set the event severity level, from 1 to 40, to reflect the importance of an event in which the service was down but AppManager successfully restarted it. The default is 25.
Event severity when auto-start is set to "No"	Set the event severity level, from 1 to 40, to reflect the importance of an event in which the service is down and that AppManager has been set to not restart it. The default is 18.
Event Notification	
Raise event if backup succeeds?	This script always raises an event when it determines that the backup has failed. In addition, you can set this parameter to **Yes** to raise an event when the script determines that the backup has succeeded. The default is Yes.
Event severity when backup succeeds	Set the event severity level, from 1 to 40, to reflect the importance of an event in which backup succeeds. The default is 25.
Event severity when backup fails	Set the event severity level, from 1 to 40, to reflect the importance an event in which backup fails. The default is 5.
Ignore DC Directory service errors?	Select **Yes** to ignore errors related to the DC Directory service, such as failures to restore, stop, and restart. The default is unselected.

19.35 ConfBridgeActiveConf

Use this Knowledge Script to monitor the number of active conferences for a Conference Bridge. If the number of active conferences exceeds the threshold, an event is raised.

19.35.1 Resource Object

CCM Conference Bridge object

19.35.2 Default Schedule

By default, this script runs every 30 minutes.

19.35.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if threshold is exceeded?	Set to **y** to raise an event if the threshold is exceeded. The default is y.
Collect data?	Set to **y** to collect data about active conferences for graphs and reports. The default is n.
Threshold - Maximum active conferences	Specify the maximum number of conferences that can be active before an event is raised. The default is 20.
Event severity when threshold is exceeded	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the threshold is exceeded. The default is 25.

19.36 ConfBridgeActiveStreams

Use this Knowledge Script to monitor the number of active streams for a Conference Bridge. This script raises an event if the number of active streams exceeds the threshold.

19.36.1 Resource Object

CCM Conference Bridge object

19.36.2 Default Schedule

By default, this script runs every 30 minutes.

19.36.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if threshold is exceeded?	Set to **y** to raise an event if the threshold is exceeded. The default is y.
Collect data?	Set to **y** to collect data about active streams for graphs and reports. The default is n.
Threshold - Maximum active streams	Specify the maximum number of streams that can be active before an event is raised. The default is 20.
Event severity when threshold is exceeded	Set the severity level, from 1 to 40, to indicate the importance of an event in which the threshold is exceeded. The default is 25.

19.37 ConfBridgeAvailStreams

Use this Knowledge Script to monitor the number of available streams for a Conference Bridge. This script raises an event if the number of available streams falls below the threshold.

19.37.1 Resource Object

CCM Conference Bridge object

19.37.2 Default Schedule

By default, this script runs every 30 minutes.

19.37.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if threshold is not met?	Set to **y** to raise an event if the number of available streams falls below the threshold. The default is y.
Collect data?	Set to **y** to collect data about available streams for graphs and reports. The default is n.
Suppress event when Role is set to Backup?	Set to **y** to suppress event generation on CallManager resources whose role is set to “backup." By suppressing event generation, you can run a script on all CallManager resources without raising an event on a resource that is not actively handling calls. The default is y.
Threshold - Minimum available streams	Specify the minimum number of streams that can be available before an event is raised. The default is 20.
Event severity when threshold is not met	Set the severity level, from 1 to 40, to indicate the importance of an event in which the threshold is not met. The default is 25.

19.38 ConfBridgeConferences

Use this Knowledge Script to monitor the number of conferences completed during an interval. This script raises an event if the number of completed conferences exceeds the threshold.

19.38.1 Resource Object

CCM Conference Bridge object

19.38.2 Default Schedule

By default, this script runs every 30 minutes.

19.38.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if threshold is exceeded?	Set to **y** to raise an event if the threshold is exceeded. The default is y.
Collect data?	Set to **y** to collect data about completed conferences for graphs and reports. The default is n.
Threshold - Maximum completed conferences	Specify the maximum number of conferences that can be completed before an event is raised. The default is 20.
Event severity when threshold is exceeded	Set the severity level, from 1 to 40, to indicate the importance of an event in which the threshold is exceeded. The default is 25.

19.39 ConfBridgeStreams

Use this Knowledge Script to monitor the number of streams on conferences that were completed during an interval. This script raises an event if the number of streams exceeds the threshold.

19.39.1 Resource Object

CCM Conference Bridge object

19.39.2 Default Schedule

By default, this script runs every 30 minutes.

19.39.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if threshold is exceeded?	Set to **y** to raise an event if the threshold is exceeded. The default is y.
Collect data?	Set to **y** to collect data about conference bridge streams for graphs and reports. The default is n.
Threshold - Maximum streams	Set the threshold for the number of streams. If the number exceeds this amount, an event is raised. The default is 20.
Event severity when threshold is exceeded	Set the severity level, from 1 to 40, to indicate the importance of an event in which the threshold is exceeded. The default is 25.

19.40 CTI_Manager

Use this Knowledge Script to monitor the number of CTI (Computer Telephony Interface) manager connections, open devices, open lines, and active CallManager links. This script raises an event if a value exceeds or falls below a threshold you set.

19.40.1 Resource Object

CCM CTI object

19.40.2 Default Schedule

By default, this script runs every 10 minutes.

19.40.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if threshold is breached?	Set to **y** to raise an event if a threshold is breached. The default is y.
Collect data?	Set to **y** to collect data about connections, devices, lines, and links for reports and graphs. The default is n.
Suppress event when Role is set to Backup?	Set to **y** to suppress event generation on CallManager resources whose role is set to "backup." By suppressing event generation, you can run a script on all CallManager resources without raising an event on a resource that is not actively handling calls. The default is y.
Event severity when threshold is breached	Set the event severity level, from 1 to 40, to indicate the importance of an event in which a threshold is exceeded. The default is 15.
Threshold - Maximum active CallManager links	Specify the maximum number of CallManager links that can be active before an event is raised. Enter -1 to ignore this parameter. The default is 10.
Threshold - Minimum active CallManager links	Specify the minimum number of CallManager links that can be active before an event is raised. Enter -1 to ignore this parameter. The default is 0.
Threshold - Maximum CTI connections	Specify the maximum number of CTI connections that can occur before an event is raised. Enter -1 to ignore this parameter. The default is 100.
Threshold - Minimum CTI connections	Specify the minimum number of CTI connections that can occur before an event is raised. Accept the default of -1 to ignore this parameter.
Threshold - Maximum open CTI devices	Specify the maximum number of CTI devices that can be open before an event is raised. Enter -1 to ignore this parameter. The default is 100.
Threshold - Minimum open CTI devices	Specify the minimum number of CTI devices that can be open before an event is raised. Accept the default of -1 to ignore this parameter.
Threshold - Maximum open CTI lines	Specify the maximum number of CTI lines that can be open before an event is raised. Enter -1 to ignore this parameter. The default is 100.

Parameter	How to Set It
Threshold - Minimum open CTI lines	Specify the minimum number of CTI lines that can be open before an event is raised. Accept the default of -1 to ignore this parameter.

19.41 DigitalOutboundBusy

Use this Knowledge Script to monitor the number of times during an interval that a call through this digital access was attempted when no ports were available. This script raises an event if the number of outbound busy attempts exceeds the threshold.

19.41.1 Resource Object

CCM Digital Access object

19.41.2 Default Schedule

By default, this script runs every 30 minutes.

19.41.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if threshold is exceeded?	Set to **y** to raise an event if the threshold is exceeded. The default is y.
Collect data?	Set to **y** to collect data about outbound busy attempts for graphs and reports. The default is n.
Threshold - Maximum outbound busy attempts	Specify the maximum number of outbound busy attempts that can occur before an event is raised. The default is 100.
Event severity when threshold is exceeded	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the template is exceeded. The default is 25.

19.42 DigitalPortsActive

Use this Knowledge Script to monitor the number of active digital ports. This script raises an event if the number of active digital ports exceeds the threshold.

19.42.1 Resource Object

CCM Digital Access object

19.42.2 Default Schedule

By default, this script runs every 30 minutes.

19.42.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if threshold is exceeded?	Set to **y** to raise an event if the threshold is exceeded. The default is y.
Collect data?	Set to **y** to collect data about active ports for graphs and reports. The default is n.
Threshold - Maximum active ports	Specify the maximum number of ports that can be active before an event is raised. The default is 20.
Event severity when threshold is exceeded	Set the severity level, from 1 to 40, to indicate the importance of the event. The default is 25.

19.43 DigitalPortsOutOfService

Use this Knowledge Script to monitor the number of digital ports that are out of service. This script raises an event if the number of out-of-service digital ports exceeds the threshold.

19.43.1 Resource Object

CCM Digital Access object

19.43.2 Default Schedule

By default, this script runs every 30 minutes.

19.43.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if threshold is exceeded?	Set to **y** to raise an event if the threshold is exceeded. The default is y.
Collect data?	Set to **y** to collect data about out-of-service ports for graphs and reports. The default is n.
Threshold - Maximum active ports	Specify the maximum number of ports that can be active before an event is raised. The default is 2.
Event severity when threshold is exceeded	Set the severity level, from 1 to 40, to indicate the importance of an event in which the number of active ports exceeds the threshold. The default is 15.

19.44 H323CallActivity

Use this Knowledge Script to monitor completed calls, attempted calls, and incomplete calls on H.323 devices for CallManager 4.2. This script raises an event if a threshold is exceeded. In addition, this script can generate the following data streams:

- Completed calls per device
- Completed calls for all devices
- Attempted calls per device
- Attempted calls for all devices
- Incomplete calls (%) per device
- Incomplete calls (%) for all devices

TIP: Use the Objects tab to limit the devices you want to monitor. Then use the parameters on the Values tab to monitor the devices individually or as a group.

19.44.1 Resource Object

CCM H.323 Device object

19.44.2 Default Schedule

By default, this script runs every five minutes.

19.44.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Job Failure Notification	
Event severity when job fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the H323CallActivity job fails. The default is 5.
Monitor Devices Individually	
Event Notification	
Raise event if completed calls exceed threshold?	Select **Yes** to raise an event if the number of completed calls exceeds the threshold that you set. The default is Yes.
Threshold - Maximum completed calls	Specify the maximum number of calls that can be completed before an event is raised. The default is 200 calls.
Event severity when completed calls exceed threshold	Set the severity level, from 1 to 40, to indicate the importance of an event in which the number of completed calls exceeds the threshold. The default is 15.

Parameter	How to Set It
Raise event if attempted calls exceed threshold?	Select **Yes** to raise an event if the number of attempted calls exceeds the threshold that you set. The default is Yes.
Threshold - Maximum attempted calls	Specify the maximum number of calls that can be attempted before an event is raised. The default is 0 attempts.
Event severity when attempted calls exceed threshold	Set the severity level, from 1 to 40, to indicate the importance of an event in which the number of attempted calls exceeds the threshold. The default is 15.
Raise event if percentage of incomplete calls exceeds threshold?	Select **Yes** to raise an event if the percentage of incomplete calls exceeds the threshold that you set. The default is Yes.
Threshold - Maximum percentage of incomplete calls	Specify the maximum percentage of incomplete calls that can occur before an event is raised. The default is 10%.
Event severity when percentage of incomplete calls exceeds threshold	Set the severity level, from 1 to 40, to indicate the importance of an event in which the percentage of incomplete calls exceeds the threshold. The default is 15.
Data Collection	
Collect data for completed calls?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the number of completed calls per monitored device. The default is unselected.
Collect data for attempted calls?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the number of attempted calls per monitored device. The default is unselected.
Collect data for percentage of incomplete calls?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the percentage of incomplete calls per monitored device. The default is unselected.
Monitor Devices as a Group	
Name for this group of devices	Specify a name by which to identify the devices you selected on the **Objects** tab. Leave this field blank to accept the default group name: `H323_Group_JobID`.
Event Notification	
Raise event if completed calls exceed threshold?	Select **Yes** to raise an event if the number of completed calls exceeds the threshold that you set. The default is Yes.
Threshold - Maximum completed calls	Specify the maximum number of calls that can be completed before an event is raised. The default is 200 calls.
Event severity when completed calls exceed threshold	Set the severity level, from 1 to 40, to indicate the importance of an event in which the number of completed calls exceeds the threshold. The default is 15.
Raise event if attempted calls exceed threshold?	Select **Yes** to raise an event if the number of attempted calls exceeds the threshold that you set. The default is Yes.
Threshold - Maximum attempted calls	Specify the maximum number of calls that can be attempted before an event is raised. The default is 0 attempts.
Event severity when attempted calls exceed threshold	Set the severity level, from 1 to 40, to indicate the importance of an event in which the number of attempted calls exceeds the threshold. The default is 15.
Raise event if percentage of incomplete calls exceeds threshold?	Select **Yes** to raise an event if the percentage of incomplete calls exceeds the threshold that you set. The default is Yes.

Parameter	How to Set It
Threshold - Maximum percentage of incomplete calls	Specify the maximum percentage of incomplete calls that can occur before an event is raised. The default is 10%.
Event severity when percentage of incomplete calls exceeds threshold	Set the severity level, from 1 to 40, to indicate the importance of an event in which the percentage of incomplete calls exceeds the threshold. The default is 15.
Data Collection	
Collect data for completed calls?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the number of completed calls per group. The default is unselected.
Collect data for attempted calls?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the number of attempted calls per group. The default is unselected.
Collect data for percentage of incomplete calls?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the percentage of incomplete calls per group. The default is unselected.

19.45 H323CallsAttempted

Use this Knowledge Script to monitor the number of calls attempted by an H.323 device during an interval. This script raises an event if a threshold is exceeded.

19.45.1 Resource Object

CCM H.323 Device object

19.45.2 Default Schedule

By default, this script runs every 30 minutes.

19.45.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if threshold is exceeded?	Set to **y** to raise an event if the threshold is exceeded. The default is y.
Collect data?	Set to **y** to collect data about attempted H.323 calls for graphs and reports. The default is n.
Threshold - Maximum attempted calls	Specify the maximum number of H.323 calls that can be attempted before an event is raised. The default is 100.
Event severity when threshold is exceeded	Set the severity level, from 1 to 40, to indicate the importance of an event in which the threshold is exceeded. The default is 25.

19.46 H323CallsInProgress

Use this Knowledge Script to monitor the number of calls in progress for an H.323 device. This script raises an event if a threshold is exceeded.

19.46.1 Resource Object

CCM H.323 Device object

19.46.2 Default Schedule

By default, this script runs every 30 minutes.

19.46.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if threshold is exceeded?	Set to **y** to raise an event if the threshold is exceeded. The default is y.
Collect data?	Set to **y** to collect data about in-progress H.323 calls for graphs and reports. The default is n.
Threshold - Maximum in-progress calls	Specify the maximum number of calls that can be in progress before an event is raised. The default is 20.
Event severity when threshold is exceeded	Set the severity level, from 1 to 40, to indicate the importance of an event in which the threshold is exceeded. The default is 25.

19.47 IIS_CpuHigh

Use this Knowledge Script to monitor CPU usage for IIS application processes. This script raises an event if CPU usage exceeds the threshold that you set.

19.47.1 Resource Object

CCM IIS Server

19.47.2 Default Schedule

By default, this script runs every five minutes.

19.47.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if CPU usage exceeds the threshold?	Set to **y** to raise an event if CPU usage exceeds the threshold. The default is y.
Collect data for CPU usage?	Set to **y** to collect data about CPU usage for reports and graphs. The default is n.
Process names	Specify the name of the application processes you want to monitor. The default is `inetinfo`. Separate multiple entries with commas. For example: `inetinfo,dllhost` **NOTE:** Do not append .exe to the process names.
Threshold - Maximum CPU usage	Specify the maximum percentage of CPU resources the selected process can use before an event is raised. The default is 60%.
Event severity when CPU usage exceeds the threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which CPU usage exceeds the threshold. The default is 8.

19.48 IIS_HealthCheck

Use this Knowledge Script to check IIS servers, Web site status, and the queue length for blocked I/O requests. If any server or Web site is not running, an event is raised. In addition, you can choose to automatically restart the IIS server or Web site. If the blocked I/O queue length is longer than the specified threshold, an event is raised.

This script monitors only Web sites (servers), not FTP sites, NNTP sites, or SMTP sites.

19.48.1 Resource Objects

CCM IIS server

CCM IIS FTP server

CCM IIS W3SRV

CCM IIS WebInst

19.48.2 Default Schedule

By default, this script runs every five minutes.

19.48.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Auto-start monitored server(s)?	Set to **y** to automatically restart down servers. The default is y.
Event severity when auto-start fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the server is down and AppManager cannot restart it. The default is 5.
Event severity when auto-start succeeds	Set the severity level, from 1 to 40, to indicate the importance of an event in which the server was down and AppManager successfully restarted it. The default is 25.
Event severity when auto-start is set to "n"	Set the severity level, from 1 to 40, to indicate the importance of an event in which the server is down and AppManager has been set not to restart the service. The default is 18.
Event severity for blocked I/O requests	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of blocked requests exceeds the threshold. The default is 5.
Threshold - Maximum blocked I/O requests	Specify the maximum number of I/O requests that can be in queue before an event is raised. The default is 0 requests.
Monitor IIS server?	Set to **y** to monitor the IIS server. The default is y.
Monitor FTP server?	Set to **y** to monitor the FTP server. The default is n.

19.49 IIS_KillTopCPUProcs

Use this Knowledge Script to monitor the CPU usage for the IIS `dllhost` and `mtx` processes. If one or both processes exceed the CPU usage threshold you set, an event is raised. You can set this script to automatically stop a process that exceeds the CPU usage threshold.

19.49.1 Resource Object

CCM IIS server

19.49.2 Default Schedule

By default, this script runs every three minutes.

19.49.3 Setting Parameters Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if kill is successful or unsuccessful?	Set to **y** to raise an event if an attempt to stop a process is successful or unsuccessful. The default is y.
Kill CPU-intensive processes?	Set to **y** to automatically stop any process that exceeds the threshold. The default is n.
Threshold - Maximum CPU usage	Specify the maximum percentage of CPU usage allowed by the dllhost and mtx processes before an event is raised. The default is 90%.
Event severity when CPU usage exceeds threshold	Set the severity level, from 1 to 40, to indicate the importance of an event in which the threshold is exceeded. The default is 10.
Event severity when kill fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which a process is exceeding the threshold and AppManager cannot stop the process. The default is 10.
Event severity when kill succeeds	Set the severity level, from 1 to 40, to indicate the importance of an event in which a process is exceeding the threshold and AppManager has successfully stopped the process. The default is 20.

19.50 IIS_MemoryHigh

Use this Knowledge Script to detect whether an IIS application process has exceeded the memory usage threshold you set. This script monitors the number of bytes of memory being used by the specified process. This script raises an event if an application process exceeds the memory usage threshold you set.

19.50.1 Resource Object

CCM IIS server

19.50.2 Default Schedule

By default, this script runs every five minutes.

19.50.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if threshold is exceeded?	Set to **y** to raise an event if a threshold is exceeded. The default is y.
Collect data?	Set to **y** to collect data about memory usage for reports and graphs. The default is n.
Process names	Specify the name of the application process you want to monitor. The default is `inetinfo`. Use a comma to separate multiple entries — do not use spaces. For example: `inetinfo,dllhost` **NOTE:** Do not append .exe to the process names.
Threshold - Maximum memory usage	Specify the maximum amount of memory the selected process can use before an event is raised. The default is 10000000 bytes.
Threshold - Maximum memory pool usage	Specify the maximum amount of memory pool the selected process can use before an event is raised. The default is 5000000 bytes.
Event severity when threshold is exceeded	Set the severity level, from 1 to 40, to indicate the importance of an event in which a threshold is exceeded. The default is 8.

19.51 IIS_RestartServer

Use this Knowledge Script to restart an IIS server. This script raises an event if the server either successfully restarts or fails to restart.

19.51.1 Resource Object

CCM IIS server

19.51.2 Default Schedule

By default, this script runs once.

19.51.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Wait N seconds before restarting	Specify the number of seconds to wait after the server is stopped before attempting to automatically restart the server. The default is five seconds.
Event severity when stop fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which AppManager cannot stop the server. The default is 5.
Event severity when restart fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which AppManager cannot restart the server. The default if 5.
Event severity when status of service is unavailable	Set the severity level, from 1 to 40, to indicate the importance of an event in which AppManager cannot determine the status of the server. The default is 10.
Event severity when stop succeeds	Set the severity level, from 1 to 40, to indicate the importance of an event in which AppManager successfully stops the server. The default is 25.
Event severity when restart succeeds	Set the severity level, from 1 to 40, to indicate the importance of an event in which AppManager successfully restarts the server. The default is 25.

19.52 IIS_ServiceUpTime

Use this Knowledge Script to monitor the uptime for Web sites and services. This script raises an event if the amount of time the sites and services are running is less than the threshold you set.

NOTE: This script supports IIS versions 5 and later.

19.52.1 Resource Objects

IIS Web server and FTP server

19.52.2 Default Schedule

By default, this script runs every one hour.

19.52.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if uptime falls below threshold?	Set to **y** to raise an event in uptime falls below the threshold. The default is y.
Collect data?	Set to **y** to collect data about service uptime for reports and graphs. The default is n.
Threshold - Minimum uptime	Specify the minimum amount of uptime that is required for Web/FTP sites and services to prevent an event from being raised. The default is 10000 seconds.
Event severity when uptime falls below threshold	Set the severity level, from 1 to 40, to indicate the importance of an event in which uptime falls below the threshold. The default is 5.

19.53 LineStatus

Use this Knowledge Script to monitor the status (number of active calls) of an individual phone line. This script raises an event if the number of calls exceeds the threshold.

19.53.1 Resource Objects

CCM Lines folder

19.53.2 Default Schedule

By default, this script runs every 30 minutes.

19.53.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if threshold is exceeded?	Set to **y** to raise an event if the threshold is exceeded. The default is y.
Collect data?	Set to **y** to collect data about line status for graphs and reports. The default is n.
Phone lines	Enter a comma-separated list of phone names to which you want to test communication.
Threshold - Maximum calls	Specify the most calls a phone line can have before an event is raised. The default is 1 call.
Event severity when threshold is exceeded	Set the severity level, from 1 to 40, to indicate the importance of an event in which the threshold is exceeded. The default is 25.

19.54 LocationBandwidth

Use this Knowledge Script to monitor bandwidth statistics for a Location resource, if that resource has been defined in CallManager.

The Locations feature in Cisco CallManager provides call admission control for centralized call processing systems. Call admission control enables you to control the audio quality of calls over a wide area (IP WAN) link by limiting the number of calls allowed on the link at the same time. A centralized system uses a single Cisco CallManager cluster to control all of the locations.

In a centralized call processing system, the Cisco CallManager cluster resides at the main location along with other devices such as phones and gateways. Remote locations, such as branch offices of your company, house additional phones and other devices, but do not contain any call processing capability. The remote locations connect to the main location and to each other by means of IP WAN links.

Calls between devices at the same location do not need call admission control because those devices reside on the same LAN, which has unlimited available bandwidth. However, calls between devices at different locations must travel over an IP WAN link, which has limited available bandwidth. The Locations feature lets you specify the maximum amount of bandwidth available for calls to and from each location, thereby limiting the number of active calls and preventing oversubscription of the bandwidth on the IP WAN links.

For bandwidth calculations, CallManager assumes that each call consumes the following amount of bandwidth:

- G.711 calls use 80 kbps
- G.723 calls use 24 kbps
- G.729 calls use 24 kbps
- GSM calls use 29 kbps
- Wideband calls use 272 kbps

19.54.1 Resource Objects

CCM Location object

19.54.2 Default Schedule

By default, this script runs every 10 minutes.

19.54.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if threshold is breached?	Set to **y** to raise an event if a threshold is breached. The default is y.
Collect data?	Set to **y** to collect data about bandwidth for reports and graphs. The default is n.

Parameter	How to Set It
Suppress event when Role is set to Backup?	Set to **y** to suppress event generation on CallManager resources whose role is set to "backup." The default is y. By suppressing event generation, you can run a script on all CallManager resources without raising an event on a resource that is not actively handling calls.
Event severity when threshold is breached	Set the severity level, from 1 to 40, to indicate the importance of the event. The default is 10.
Threshold - Minimum available bandwidth	Specify the minimum amount of bandwidth that can be available before an event is raised. The default is 500 kbps.
Threshold - Maximum bandwidth in use	Specify the maximum amount of bandwidth that can be in use before an event is raised. The default is 75%.

19.55 LocationOutOfBandwidth

Use this Knowledge Script to monitor the number of times that calls through a particular Location failed due to lack of bandwidth. This script raises an event if the number of failures exceeds the threshold that you set. In addition, this script generates a data stream for the number of bandwidth failures.

19.55.1 Resource Object

CCM Location object

19.55.2 Default Schedule

By default, this script runs every 10 minutes.

19.55.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Job Failure Notification	
Event severity when job fails	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the LocationOutOfBandwidth job fails. The default is 5.
Monitor Out of Bandwidth Failures	
Event Notification	
Raise event if bandwidth failures exceed threshold?	Select **Yes** to raise an event if the number of calls that fail due to lack of bandwidth exceeds the threshold that you set. The default is 3 calls
Event severity when bandwidth failures exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of bandwidth failures exceeds the threshold that you set. The default is 15.
Data Collection	
Collect data for bandwidth failures?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the number of calls that failed due to lack of bandwidth.

19.56 LossOfHardwarePhones

Use this Knowledge Script to monitor the number of registered hardware phones. This script raises an event if the number of lost phones exceeds a specified number or percentage during the monitored interval.

This script is a member of a Recommended Knowledge Script Group. For more information, see "Recommended Knowledge Script Groups" on page 1057.

You can also use this script to help you monitor phone status. For more information, see CCM_PhoneInventory.

19.56.1 Comparing Results of LossOfHardwarePhones and CCM_PhoneInventory

You can use the LossOfHardwarePhones script to launch an Action script that, in turn, launches the CCM_PhoneInventory script. By doing so, you can improve upon the results you get from LossOfHardwarePhones.

For example, say LossOfHardwarePhones indicates you have lost five phones since the last time it ran. But you configured the script to launch Action_RunPhoneInventory when the lost-phone event was raised, so CCM_PhoneInventory further refined the results. Based on criteria you selected, CCM_PhoneInventory identified the five phones by Directory Number, or Device Pool, or Subnet, or several other filtering options.

For several reasons, however, it is possible your results were inconsistent between LossOfHardwarePhones and CCM_PhoneInventory. Although you cannot fix the consistency problem, you can understand why it occurred:

- The scripts obtain phone data from two different sources. LossOfHardwarePhones uses the Performance Monitor counters on the Subscriber; CCM_PhoneInventory makes an API call to query phone information from the Publisher.
- The Subscriber and the Publisher can be out of sync because of the difference between timing windows or a lack of connectivity between the two devices. The information that is available from the two devices can change between the time LossOfHardwarePhones checks the counters and CCM_PhoneInventory makes its API call.
- Even if the Subscriber and the Publisher are in sync, differences in filtering can produce inconsistent results. The data from LossOfHardwarePhones is unfiltered — it includes everything; the data from CCM_PhoneInventory can be filtered by subnet, Directory Number, or several other filtering options.

19.56.2 Resource Object

CCM Subscriber

19.56.3 Default Schedule

By default, this script runs every five minutes.

19.56.4 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Monitor Loss of Hardware Phones	
Event Notification	
Raise event if threshold is exceeded?	Select **Yes** to raise an event if a threshold is crossed. The default is Yes.
Threshold type	Select whether you want to set a threshold for the **Number** of lost phones or a **Percent** of hardware phones. The default is Percent.
Threshold - Maximum # lost hardware phones	Specify the maximum number of hardware phones that can be lost before an event is raised. The default is 24.
Threshold - Maximum % lost hardware phones	Specify the maximum percentage of hardware phones that can be lost before an event is raised. The default is 10%.
Event severity when threshold is exceeded	Set the severity level, from 1 to 40, to indicate the importance of an event in which a threshold is exceeded. The default is 10.
Data Collection	
Collect data for lost hardware phones?	Select **Yes** to collect data about lost phones for graphs and reports. The default is unselected.

19.57 MGCP_FXO

Use this Knowledge Script to monitor completed calls, outbound busy attempts, and blocked calls for Media Gateway Control Protocol (MGCP) Foreign Exchange Office (FXO) devices in CallManager 3.1 and 4.2.

This script raises an event if a threshold is exceeded. In addition, this script can generate the following data streams:

- Completed calls per device
- Completed calls for all devices
- Busy attempts per device
- Busy attempts for all devices
- Blocked calls (%) per device
- Blocked calls (%) for all devices

This script collects the data used by Report_MGCPDeviceUtil.

TIP: Use the Objects tab to limit the devices you want to monitor. Then use the parameters on the Values tab to monitor the devices individually or as a group.

19.57.1 Resource Object

CCM MGCP FXO object

19.57.2 Default Schedule

By default, this script runs every 10 minutes.

19.57.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Job Failure Notification	
Event severity when job fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the MGCP_FXO job fails. The default is 5.
Additional event information	Provide any additional message text that you want to append to the Detailed Event Message of an event. You can enter up to 128 characters.
Monitor Devices Individually	
Event Notification	

Parameter	How to Set It
Raise event if completed calls exceed threshold?	Select **Yes** to raise an event if the number of completed calls exceeds the threshold that you set. The default is Yes.
Threshold - Maximum completed calls	Specify the maximum number of calls that can be completed before an event is raised. The default is 200 calls.
Event severity when completed calls exceed threshold	Set the severity level, from 1 to 40, to indicate the importance of an event in which the number of completed calls exceeds the threshold. The default is 15.
Raise event if busy attempts exceed threshold?	Select **Yes** to raise an event if the number of busy attempts exceeds the threshold that you set. The default is Yes.
Threshold - Maximum busy attempts	Specify the maximum number of busy attempts that can occur before an event is raised. The default is 0 attempts.
Event severity when busy attempts exceed threshold	Set the severity level, from 1 to 40, to indicate the importance of an event in which the number of busy attempts exceeds the threshold. The default is 15.
Raise event if percentage of blocked calls exceeds threshold?	Select **Yes** to raise an event if the percentage of blocked calls exceeds the threshold that you set. The default is Yes.
Threshold - Maximum percentage of blocked calls	Specify the maximum percentage of blocked calls that can occur before an event is raised. The default is 10%.
Event severity when percentage of blocked calls exceeds threshold	Set the severity level, from 1 to 40, to indicate the importance of an event in which the percentage of blocked calls exceeds the threshold. The default is 15.
Data Collection	
Collect data for completed calls?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the number of completed calls per monitored device. The default is unselected.
Collect data for busy attempts?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the number of busy attempts per monitored device. The default is unselected.
Collect data for percentage of blocked calls?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the percentage of blocked calls per monitored device. The default is unselected.
Monitor Devices as a Group	
Name for this group of devices	Specify a name by which to identify the devices you selected on the Objects tab. Leave this field blank to accept the default group name: `FXO_Group_JobID`.
Event Notification	
Raise event if completed calls exceed threshold?	Select **Yes** to raise an event if the number of completed calls exceeds the threshold that you set. The default is Yes.
Threshold - Maximum completed calls	Specify the maximum number of calls that can be completed before an event is raised. The default is 200 calls.
Event severity when completed calls exceed threshold	Set the severity level, from 1 to 40, to indicate the importance of an event in which the number of completed calls exceeds the threshold. The default is 15.
Raise event if busy attempts exceed threshold?	Select **Yes** to raise an event if the number of busy attempts exceeds the threshold that you set. The default is Yes.

Parameter	How to Set It
Threshold - Maximum busy attempts	Specify the maximum number of busy attempts that can occur before an event is raised. The default is 0 attempts.
Event severity when busy attempts exceed threshold	Set the severity level, from 1 to 40, to indicate the importance of an event in which the number of busy attempts exceeds the threshold. The default is 15.
Raise event if percentage of blocked calls exceeds threshold?	Select **Yes** to raise an event if the percentage of blocked calls exceeds the threshold that you set. The default is Yes.
Threshold - Maximum percentage of blocked calls	Specify the maximum percentage of blocked calls that can occur before an event is raised. The default is 10%.
Event severity when percentage of blocked calls exceeds threshold	Set the severity level, from 1 to 40, to indicate the importance of an event in which the percentage of blocked calls exceeds the threshold. The default is 15.
Data Collection	
Collect data for completed calls?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the number of completed calls per group. The default is unselected.
Collect data for busy attempts?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the number of busy attempts per group. The default is unselected.
Collect data for percentage of blocked calls?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the percentage of blocked calls per group. The default is unselected.

19.58 MGCP_FXS

Use this Knowledge Script to monitor completed calls, outbound busy attempts, and blocked calls for Media Gateway Control Protocol (MGCP) Foreign Exchange Station (FXS) devices in CallManager 3.1 and 4.2.

This script raises an event if a threshold is exceeded. In addition, this script can generate the following data streams:

- Completed calls per device
- Completed calls for all devices
- Busy attempts per device
- Busy attempts for all devices
- Blocked calls (%) per device
- Blocked calls (%) for all devices

This script collects the data used by Report_MGCPDeviceUtil.

TIP: Use the Objects tab to limit the devices you want to monitor. Then use the parameters on the Values tab to monitor the devices individually or as a group.

19.58.1 Resource Object

CCM MGCP FXS object

19.58.2 Default Schedule

By default, this script runs every 10 minutes.

19.58.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Job Failure Notification	
Event severity when job fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the MGCP_FXS job fails. The default is 5.
Additional event information	Provide any additional message text that you want to append to the Detailed Event Message of an event. You can enter up to 128 characters.
Monitor Devices Individually	
Event Notification	

Parameter	How to Set It
Raise event if completed calls exceed threshold?	Select **Yes** to raise an event if the number of completed calls exceeds the threshold that you set. The default is Yes.
Threshold - Maximum completed calls	Specify the maximum number of calls that can be completed before an event is raised. The default is 200 calls.
Event severity when completed calls exceed threshold	Set the severity level, from 1 to 40, to indicate the importance of an event in which the number of completed calls exceeds the threshold. The default is 15.
Raise event if busy attempts exceed threshold?	Select **Yes** to raise an event if the number of busy attempts exceeds the threshold that you set. The default is Yes.
Threshold - Maximum busy attempts	Specify the maximum number of busy attempts that can occur before an event is raised. The default is 0 attempts.
Event severity when busy attempts exceed threshold	Set the severity level, from 1 to 40, to indicate the importance of an event in which the number of busy attempts exceeds the threshold. The default is 15.
Raise event if percentage of blocked calls exceeds threshold?	Select **Yes** to raise an event if the percentage of blocked calls exceeds the threshold that you set. The default is Yes.
Threshold - Maximum percentage of blocked calls	Specify the maximum percentage of blocked calls that can occur before an event is raised. The default is 10%.
Event severity when percentage of blocked calls exceeds threshold	Set the severity level, from 1 to 40, to indicate the importance of an event in which the percentage of blocked calls exceeds the threshold. The default is 15.
Data Collection	
Collect data for completed calls?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the number of completed calls per monitored device. The default is unselected.
Collect data for busy attempts?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the number of busy attempts per monitored device. The default is unselected.
Collect data for percentage of blocked calls?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the percentage of blocked calls per monitored device. The default is unselected.
Monitor Devices as a Group	
Name for this group of devices	Specify a name by which to identify the devices you selected on the Objects tab. Leave this field blank to accept the default group name: `FXS_Group_JobID`.
Event Notification	
Raise event if completed calls exceed threshold?	Select **Yes** to raise an event if the number of completed calls exceeds the threshold that you set. The default is Yes.
Threshold - Maximum completed calls	Specify the maximum number of calls that can be completed before an event is raised. The default is 200 calls.
Event severity when completed calls exceed threshold	Set the severity level, from 1 to 40, to indicate the importance of an event in which the number of completed calls exceeds the threshold. The default is 15.
Raise event if busy attempts exceed threshold?	Select **Yes** to raise an event if the number of busy attempts exceeds the threshold that you set. The default is Yes.

Parameter	How to Set It
Threshold - Maximum busy attempts	Specify the maximum number of busy attempts that can occur before an event is raised. The default is 0 attempts.
Event severity when busy attempts exceed threshold	Set the severity level, from 1 to 40, to indicate the importance of an event in which the number of busy attempts exceeds the threshold. The default is 15.
Raise event if percentage of blocked calls exceeds threshold?	Select **Yes** to raise an event if the percentage of blocked calls exceeds the threshold that you set. The default is Yes.
Threshold - Maximum percentage of blocked calls	Specify the maximum percentage of blocked calls that can occur before an event is raised. The default is 10%.
Event severity when percentage of blocked calls exceeds threshold	Set the severity level, from 1 to 40, to indicate the importance of an event in which the percentage of blocked calls exceeds the threshold. The default is 15.
Data Collection	
Collect data for completed calls?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the number of completed calls per group. The default is unselected.
Collect data for busy attempts?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the number of busy attempts per group. The default is unselected.
Collect data for percentage of blocked calls?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the percentage of blocked calls per group. The default is unselected.

19.59 MGCP_Gateway_CCM30

Use this Knowledge Script to monitor the station ports and voice channels for Media Gateway Control Protocol (MGCP) devices in CallManager 3.0. This script raises an event if a threshold is exceeded.

19.59.1 Resource Object

CCM MGCP Gateway object

19.59.2 Default Schedule

By default, this script runs every 10 minutes.

19.59.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if threshold is exceeded?	Set to **y** to raise an event if a threshold is exceeded. The default is y.
Collect data?	Set to **y** to collect data about station ports and voice channels for graphs and reports. The default is n.
Event severity when threshold is exceeded	Set the severity level, from 1 to 40, to indicate the importance of an event in which a threshold is exceeded. The default is 15.
Monitor station ports?	Set to **y** to monitor station ports. The default is y.
Threshold - Maximum active station ports	Specify the maximum number of station ports that can be active before an event is raised. The default is 10 ports.
Monitor voice channels?	Set to **y** to monitor voice channels. The default is n.
Threshold - Maximum active voice channels	Specify the maximum number of voice channels that can be active before an event is raised. The default is 10 channels.

19.60 MGCP_Gateway_CCM31

Use this Knowledge Script to monitor the number of active MGCP Gateway station ports or voice channels for Media Gateway Control Protocol (MGCP) devices in CallManager 3.1 and later.

This script collects the data used by the Report_MGCPGatewayUsage Knowledge Script.

19.60.1 Resource Object

CCM MGCP Gateway object

19.60.2 Default Schedule

By default, this script runs every 10 minutes.

19.60.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if threshold is breached?	Set to **y** to raise an event if a threshold is breached. The default is y.
Collect data?	Set to **y** to collect data about station ports and voice channels for reports and graphs. The default is n.
Event severity when threshold is breached	Set the severity level, from 1 to 40, to indicate the importance of the event. The default is 15.
Suppress event when Role is set to Backup?	Set to **y** to suppress event generation on CallManager resources whose role is set to "backup." The default is y. By suppressing event generation, you can run a script on all CallManager resources without raising an event on a resource that is not actively handling calls.
Monitor FXO ports?	Set to **y** to monitor FXO (foreign exchange office) ports. The default is n.
Threshold - Maximum active FXO ports	Specify the maximum number of FXO ports that can be active before an event is raised. The default is 10 ports.
Threshold - Minimum FXO ports in service	Specify the minimum number of FXO ports that must be in service to prevent an event from being raised. Accept the default of **0** to ignore this event.
Monitor FXS ports?	Set to **y** to monitor FXS (foreign exchange station) ports. The default is n.
Threshold - Maximum active FXS ports	Specify the maximum number of FXS ports that can be active before an event is raised. The default is 10 ports.
Threshold - Minimum FXS ports in service	Specify the minimum number of FXS ports that must be in service to prevent an event from being raised. Accept the default of **0** to ignore this event.

Parameter	How to Set It
Monitor PRI voice channels?	Set to **y** to monitor PRI (primary rate interface) channels. The default is y.
Threshold - Maximum active PRI voice channels	Specify the maximum number of PRI voice channels that can be active before an event is raised. The default is 10 channels.
Threshold - Minimum PRI channels in service	Specify the minimum number of PRI voice channels that must be in service to prevent an event from being raised. Accept the default of **0** to ignore this event.
Monitor T1_CAS voice channels?	Set to **y** to monitor T1-CAS (channel associated signaling) channels. The default is n.
Threshold - Maximum active T1-CAS voice channels	Specify the maximum number of T1 CAS voice channels that can be active before an event is raised The default is 10 channels.
Threshold - Minimum T1-CAS channels in service	Specify the minimum number of T1-CAS voice channels that must be in service to prevent an event from being raised. Accept the default of **0** to ignore this event.

19.61 MGCP_GatewayCheck

Use this Knowledge Script to monitor your CallManager for new and missing MGCP gateways. With each iteration of the job, this script creates a list of the MGCP gateways that are registered to the CallManager, and then compares the latest list information with the information from the previous list.

The list created by this script is sorted by the description of the MGCP gateway that you entered into CallManager.

19.61.1 Resource Object

CCM MGCP Gateway folder

19.61.2 Default Schedule

By default, this script runs every 15 minutes.

19.61.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if new or missing gateways are found?	Set to **y** to raise an event if new MGCP gateways are found or if any gateway is missing within an interval that you specify. The default is y.
File name for saving list	Provide a name for the list of new or missing MGCP gateways. The default is `NQMGCPList`.
Raise event for the initial list?	Set to **y** to raise an event for the first time that this script creates a list. The default is n.
Event severity when MGCP gateways are missing	Set the severity level, from 1 to 40, to reflect the importance of an event in which MGCP gateways are missing. The default is 15.
Event severity when new MGCP gateways are found	Set the severity level, from 1 to 40, to reflect the importance of an event in which new MGCP gateways are found. Enter **0** if you do not want to raise an event. The default is 30.

19.62 MGCP_PRI

Use this Knowledge Script to monitor completed calls, outbound busy attempts, blocked calls, and data link availability for Media Gateway Control Protocol (MGCP) Primary Rate Interface (PRI) devices in CallManager 3.1 and 4.2.

This script raises an event if a threshold is exceeded. In addition, this script can generate the following data streams:

- Completed calls per device
- Completed calls for all devices
- Busy attempts per device
- Busy attempts for all devices
- Blocked calls (%) per device
- Blocked calls (%) for all devices

This script collects the data used by Report_MGCPDeviceUtil.

TIP: Use the Objects tab to limit the devices you want to monitor. Then use the parameters on the Values tab to monitor the devices individually or as a group.

19.62.1 Resource Object

CCM MGCP PRI object

19.62.2 Default Schedule

By default, this script runs every 10 minutes.

19.62.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Job Failure Notification	
Event severity when job fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the MGCP_PRI job fails. The default is 5.
Additional event information	Provide any additional message text that you want to append to the Detailed Event Message of an event. You can enter up to 128 characters.
Monitor Devices Individually	
Event Notification	

Parameter	How to Set It
Raise event if completed calls exceed threshold?	Select **Yes** to raise an event if the number of completed calls exceeds the threshold that you set. The default is Yes.
Threshold - Maximum completed calls	Specify the maximum number of calls that can be completed before an event is raised. The default is 200 calls.
Event severity when completed calls exceed threshold	Set the severity level, from 1 to 40, to indicate the importance of an event in which the number of completed calls exceeds the threshold. The default is 15.
Raise event if busy attempts exceed threshold?	Select **Yes** to raise an event if the number of busy attempts exceeds the threshold that you set. The default is Yes.
Threshold - Maximum busy attempts	Specify the maximum number of busy attempts that can occur before an event is raised. The default is 0 attempts.
Event severity when busy attempts exceed threshold	Set the severity level, from 1 to 40, to indicate the importance of an event in which the number of busy attempts exceeds the threshold. The default is 15.
Raise event if percentage of blocked calls exceeds threshold?	Select **Yes** to raise an event if the percentage of blocked calls exceeds the threshold that you set. The default is Yes.
Threshold - Maximum percentage of blocked calls	Specify the maximum percentage of blocked calls that can occur before an event is raised. The default is 10%.
Event severity when percentage of blocked calls exceeds threshold	Set the severity level, from 1 to 40, to indicate the importance of an event in which the percentage of blocked calls exceeds the threshold. The default is 15.
Raise event if data link out of service?	Select **Yes** to raise an event if the PRI data link is out of service. The default is Yes.
Event severity when data link out of service	Set the severity level, from 1 to 40, to indicate the importance of an event in which the PRI data link is out of service. The default is 15.
Data Collection	
Collect data for completed calls?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the number of completed calls per monitored device. The default is unselected.
Collect data for busy attempts?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the number of busy attempts per monitored device. The default is unselected.
Collect data for percentage of blocked calls?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the percentage of blocked calls per monitored device. The default is unselected.
Monitor Devices as a Group	
Name for this group of devices	Specify a name by which to identify the devices you selected on the Objects tab. Leave this field blank to accept the default group name: `PRI_Group_JobID`.
Event Notification	
Raise event if completed calls exceed threshold?	Select **Yes** to raise an event if the number of completed calls exceeds the threshold that you set. The default is Yes.
Threshold - Maximum completed calls	Specify the maximum number of calls that can be completed before an event is raised. The default is 200 calls.

Parameter	How to Set It
Event severity when completed calls exceed threshold	Set the severity level, from 1 to 40, to indicate the importance of an event in which the number of completed calls exceeds the threshold. The default is 15.
Raise event if busy attempts exceed threshold?	Select **Yes** to raise an event if the number of busy attempts exceeds the threshold that you set. The default is Yes.
Threshold - Maximum busy attempts	Specify the maximum number of busy attempts that can occur before an event is raised. The default is 0 attempts.
Event severity when busy attempts exceed threshold	Set the severity level, from 1 to 40, to indicate the importance of an event in which the number of busy attempts exceeds the threshold. The default is 15.
Raise event if percentage of blocked calls exceeds threshold?	Select **Yes** to raise an event if the percentage of blocked calls exceeds the threshold that you set. The default is Yes.
Threshold - Maximum percentage of blocked calls	Specify the maximum percentage of blocked calls that can occur before an event is raised. The default is 10%.
Event severity when percentage of blocked calls exceeds threshold	Set the severity level, from 1 to 40, to indicate the importance of an event in which the percentage of blocked calls exceeds the threshold. The default is 15.
Data Collection	
Collect data for completed calls?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the number of completed calls per group. The default is unselected.
Collect data for busy attempts?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the number of busy attempts per group. The default is unselected.
Collect data for percentage of blocked calls?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the percentage of blocked calls per group. The default is unselected.

19.63 MGCP_PRI_Channels

Use this Knowledge Script to monitor an individual MGCP PRI device for active and out-of-service channels. In addition, you can run this script to monitor the number of active channels for a group of MGCP PRI devices. To monitor a group, run the script on the MGCP PRI Devices folder in the TreeView pane (instead of running it on an individual PRI device) and then use the Objects tab to select the PRI devices that you want to include in the group.

The first time you run this script, you can raise an informational event whose event message will contain the current status of all the channels being monitored. The possible statuses are listed below:

- 0 (unknown) - Indicates this channel is not defined. For example, channels 25-31 on T1-PRI devices are not defined. These channels are used by E1-PRI devices.
- 1 (out of service) - Indicates this channel is not available for use.
- 2 (idle) - Indicates this channel has no active call and is ready for use.
- 3 (busy) - Indicates an active call on this channel.
- 4 (reserved) - Indicates this channel has been reserved for use as a D-Channel or as a Synch-Channel for E1.

The detailed event messages and detailed data stream messages will contain the number of channels that are active or out-of-service.

The detailed event message and detailed data stream messages for a group of devices will contain the number of active channels for each device in the group.

This script collects the data used by the Report_MGCPChannelUsage Knowledge Script.

NOTE: If you use this script to monitor a group of devices, NetIQ Corporation recommends that you make a copy of the script and then rename it to something more specific to your needs, such as "Headquarter_Gateway_Activity" or "PSTN_Gateway_Actvity."

19.63.1 Resource Object

CCM MGCP PRI object

19.63.2 Default Schedule

By default, this script runs every five minutes.

19.63.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if threshold is exceeded?	Set to **y** to raise an event if a threshold is exceeded. The default is y.

Parameter	How to Set It
Collect data?	Set to **y** to collect data for reports and graphs. The default is y. This script can collect data streams for the number of active channels and, optionally, the number of out-of-service channels.
Monitor these channels	Provide a range or a comma-separated list of the channel numbers that you want to monitor. You can enter a combination of range and list, such as 1-5,9,10,11,20-23. Separate each item by a comma. Valid channel numbers are 1-31. The default is 1-23.
Exclude these channels	Provide a range or a comma-separated list of the channel numbers that you want to exclude from monitoring. You can enter a combination of range and list, such as 1-5,9,10,11,20-23. Separate each item by a comma. Valid channel numbers are 1-31.
Threshold - Maximum active channels for any device	Specify the maximum number of monitored channels that can be active (status = 3) before an event is raised. The default is 20.
Event severity when active channels exceed the threshold	Set the severity level, from 1 to 40, to indicate the importance of an event in which the number of active channels exceeds the threshold. The default is 15.
Monitor out-of-service channels?	Set to **y** to monitor out-of-service channels. The default is y.
Threshold - Maximum out-of-service channels	Specify the maximum number of monitored channels that can be out-of-service (status = 1) for an individual device. If the number of out-of-service channels exceeds this amount, an event is raised. The default is 0 channels.
Event severity when out-of-service channels exceed the threshold	Set the severity level, from 1 to 40, to indicate the importance of an event in which the number of out-of-service channels exceeds the threshold. The default is 5.
Collect data for out-of-service channels?	Set to **y** to collect data about the number of out-of-service channels for reports and graphs. The default is n.
Raise event with current status?	Set to **y** to create an event that indicates the current status of the channels. The default is n.
Additional event information	Enter any additional message text that you want to append to the Detailed Event Message for any events that are raised. You can enter up to 128 characters.
Monitor totals for a group of devices	Set to **y** to monitor all the devices in the group for which you are running this script. The default is y.
Name this group of PRI devices	If you are monitoring a group of PRI devices, enter a name for the group. This name will be displayed on events and charts. If no name is entered, this script generates a default name based on the current time.
Threshold - Maximum active channels for group of devices	Specify the maximum number of monitored channels that can be active (status = 3) for all devices in the group. If the number of active channels exceeds this amount, an event is raised. The default is 1250 channels.
Event severity when active channels for group exceed the threshold	Set the severity level, from 1 to 40, to indicate that the number of active channels for the entire group of PRI devices being monitored has exceeded the threshold. The default is 15.

19.64 MGCP_T1CAS

Use this Knowledge Script to monitor completed calls, outbound busy attempts, blocked calls, and data link availability for Media Gateway Control Protocol (MGCP) T1-CAS devices in CallManager 3.1 and 4.2.

This script raises an event if a threshold is exceeded. In addition, this script can generate the following data streams:

- Completed calls per device
- Completed calls for all devices
- Busy attempts per device
- Busy attempts for all devices
- Blocked calls (%) per device
- Blocked calls (%) for all devices

This script collects the data used by Report_MGCPDeviceUtil.

TIP: Use the Objects tab to limit the devices you want to monitor. Then use the parameters on the Values tab to monitor the devices individually or as a group.

19.64.1 Resource Object

CCM MGCP T1-CAS object

19.64.2 Default Schedule

By default, this script runs every 10 minutes.

19.64.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Job Failure Notification	
Event severity when job fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the MGCP_T1CAS job fails. The default is 5.
Additional event information	Provide any additional message text that you want to append to the Detailed Event Message of an event. You can enter up to 128 characters.
Monitor Devices Individually	
Event Notification	

Parameter	How to Set It
Raise event if completed calls exceed threshold?	Select **Yes** to raise an event if the number of completed calls exceeds the threshold that you set. The default is Yes.
Threshold - Maximum completed calls	Specify the maximum number of calls that can be completed before an event is raised. The default is 200 calls.
Event severity when completed calls exceed threshold	Set the severity level, from 1 to 40, to indicate the importance of an event in which the number of completed calls exceeds the threshold. The default is 15.
Raise event if busy attempts exceed threshold?	Select **Yes** to raise an event if the number of busy attempts exceeds the threshold that you set. The default is Yes.
Threshold - Maximum busy attempts	Specify the maximum number of busy attempts that can occur before an event is raised. The default is 0 attempts.
Event severity when busy attempts exceed threshold	Set the severity level, from 1 to 40, to indicate the importance of an event in which the number of busy attempts exceeds the threshold. The default is 15.
Raise event if percentage of blocked calls exceeds threshold?	Select **Yes** to raise an event if the percentage of blocked calls exceeds the threshold that you set. The default is Yes.
Threshold - Maximum percentage of blocked calls	Specify the maximum percentage of blocked calls that can occur before an event is raised. The default is 10%.
Event severity when percentage of blocked calls exceeds threshold	Set the severity level, from 1 to 40, to indicate the importance of an event in which the percentage of blocked calls exceeds the threshold. The default is 15.
Raise event if data link out of service?	Select **Yes** to raise an event if the T1-CAS data link is out of service. The default is Yes.
Event severity when data link out of service	Set the severity level, from 1 to 40, to indicate the importance of an event in which the T1-CAS data link is out of service. The default is 15.
Data Collection	
Collect data for completed calls?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the number of completed calls per monitored device. The default is unselected.
Collect data for busy attempts?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the number of busy attempts per monitored device. The default is unselected.
Collect data for percentage of blocked calls?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the percentage of blocked calls per monitored device. The default is unselected.
Monitor Devices as a Group	
Name for this group of devices	Specify a name by which to identify the devices you selected on the Objects tab. Leave this field blank to accept the default group name: `T1CAS_Group_JobID`.
Event Notification	
Raise event if completed calls exceed threshold?	Select **Yes** to raise an event if the number of completed calls exceeds the threshold that you set. The default is Yes.
Threshold - Maximum completed calls	Specify the maximum number of calls that can be completed before an event is raised. The default is 200 calls.

Parameter	How to Set It
Event severity when completed calls exceed threshold	Set the severity level, from 1 to 40, to indicate the importance of an event in which the number of completed calls exceeds the threshold. The default is 15.
Raise event if busy attempts exceed threshold?	Select **Yes** to raise an event if the number of busy attempts exceeds the threshold that you set. The default is Yes.
Threshold - Maximum busy attempts	Specify the maximum number of busy attempts that can occur before an event is raised. The default is 0 attempts.
Event severity when busy attempts exceed threshold	Set the severity level, from 1 to 40, to indicate the importance of an event in which the number of busy attempts exceeds the threshold. The default is 15.
Raise event if percentage of blocked calls exceeds threshold?	Select **Yes** to raise an event if the percentage of blocked calls exceeds the threshold that you set. The default is Yes.
Threshold - Maximum percentage of blocked calls	Specify the maximum percentage of blocked calls that can occur before an event is raised. The default is 10%.
Event severity when percentage of blocked calls exceeds threshold	Set the severity level, from 1 to 40, to indicate the importance of an event in which the percentage of blocked calls exceeds the threshold. The default is 15.
Data Collection	
Collect data for completed calls?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the number of completed calls per group. The default is unselected.
Collect data for busy attempts?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the number of busy attempts per group. The default is unselected.
Collect data for percentage of blocked calls?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the percentage of blocked calls per group. The default is unselected.

19.65 MGCP_T1CAS_Channels

Use this Knowledge Script to monitor an individual MGCP T1-CAS device for active and out-of-service channels. In addition, you can run this script to monitor the number of active channels for a group of MGCP T1-CAS devices. To monitor a group, run the script on the MGCP T1-CAS Devices folder, instead of running it on an individual T1-CAS device. Then use the Objects tab to select the specific T1-CAS devices you want to include in the group.

The first time you run this script, you can choose to raise an informational event whose event message will contain the current status of all the channels being monitored. The possible statuses are listed below:

- 0 (unknown) - Indicates this channel is not defined.
- 1 (out of service) - Indicates this channel is not available for use.
- 2 (idle) - Indicates this channel has no active call and is ready for use.
- 3 (busy) - Indicates an active call on this channel.
- 4 (reserved) - Indicates this channel has been reserved for use as a D-Channel or as a Synch-Channel for E1.

This script collects the data used by the Report_MGCPChannelUsage Knowledge Script.

The detailed event messages and detailed data stream messages will contain the number of channels that are active or out-of-service.

The detailed event message and detailed data stream messages for a group of devices will contain the number of active channels for each device in the group.

NOTE: If you use this script to monitor a group of devices, NetIQ Corporation recommends making a copy of the script and renaming it to something more specific to your needs, such as "Headquarter_Gateway_Activity" or "PSTN_Gateway_Actvity."

19.65.1 Resource Object

CCM MGCP T1-CAS object

19.65.2 Default Schedule

By default, this script runs every five minutes.

19.65.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if threshold is exceeded?	Set to **y** to raise an event if a threshold is exceeded. The default is y.
Collect data?	Set to **y** to collect data for reports and graphs.The default is y. This script can collect data streams for the number of active channels and, optionally, the number of out-of-service channels.

Parameter	How to Set It
Monitor these channels	Specify a range or a comma-separated list of the channel numbers that you want to monitor. You can enter a combination of range and list, such as 1-5,9,10,11,20-23. Separate each item by a comma. Valid channel numbers are 1-31. The default is 1-23.
Exclude these channels	Specify a range or a comma-separated list of the channel numbers that you want to exclude from monitoring. You can enter a combination of range and list, such as 1-5,9,10,11,20-23. Separate each item by a comma. Valid channel numbers are 1-31.
Threshold - Maximum active channels for any device	Specify the maximum number of monitored channels that can be active (status = 3) before an event is raised. The default is 20 channels.
Event severity when active channels exceed the threshold	Set the severity level, from 1 to 40, to indicate the importance of the event. The default is 15.
Monitor out-of-service channels?	Set to **y** to monitor out-of-service channels. The default is y.
Threshold - Maximum out-of-service channels	Specify the maximum number of monitored channels that can be out-of-service (status = 1) for an individual device before an event is raised. The default is 0.
Event severity when out-of-service channels exceed the threshold	Set the severity level, from 1 to 40, to indicate the importance of an event in which out-of-service channels exceed the threshold. The default is 5.
Collect data for out-of-service channels?	Set to **y** to collect data about the number of out-of-service channels for reports and graphs. The default is n.
Raise event with current status?	Set to **y** to raise an event that indicates the current status of the channels. The default is n.
Additional event information	Provide any additional message text that you want to append to the Detailed Event Message of an event. You can enter up to 128 characters.
Monitor totals for a group of devices?	Set to **y** to monitor all the devices in the group for which you are running this script. The default is y.
Name this group of T1CAS devices	If you are monitoring a group of T1CAS devices, enter a name for the group. This name will be displayed on events and charts. If no name is entered, this script generates a default name based on the current time.
Threshold - Maximum active channels for all devices in group	Specify the maximum number of monitored channels that can be active (status = 3) for all devices in the group. If the number of active channels exceeds this amount, an event is raised. The default is 1250 channels.
Event severity when active channels for group exceed the threshold	Set the severity level, from 1 to 40, to indicate the importance of an event in which the group's active channels exceed the threshold. The default is 15.

19.66 MLA_Logins

Use this Knowledge Script to scan CallManager MLA (multi-level administration) log files for successful and failed logins. In addition to information about successful and failed logins, the log files contain the user name, group name, date, and time of the login session.

Multi-level administration allows users with full access to configure different levels of administration access for CallManager administrators. Users with full access configure functional groups, user groups, and access privileges for user groups. In general, full-access users configure the access of other users to Cisco CallManager Administration.

The first time you run this script, you can check for the number of logins during the past n hours. Subsequent runs will check for the number of logins within the specified interval.

19.66.1 Resource Object

CCM MLA object

19.66.2 Default Schedule

By default, this script runs every one hour.

19.66.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if threshold is exceeded?	Set to **y** to raise an event if a threshold is exceeded. The default is y.
Collect data?	Set to **y** to collect data about successful and failed logins for reports and graphs. The default is n.
Log file directory	Enter the directory path to the log file. The default is `c:\ciscoWebs\MLA\logs`
On first run, scan for logins in the past N hours	Enter the number of hours of log file entries through which the script will search for trace files. For instance, if you enter 15, the script will search through the last 15 hours of log file entries. The default is 1 hour. Setting this parameter to a high value may result in high CPU usage.
Threshold - Maximum failed logins	Specify the maximum number of logins that can fail before an event is raised. The default is 3 logins.
Threshold - Maximum successful logins	Set the threshold for the number of logons that have succeeded during the specified interval. If the number of successful logons exceeds this amount, an event is raised. The default is 3 logins.
Event severity when failed logins exceed the threshold	Set the severity level, from 1 to 40, to indicate the importance of an event in which the number of failed logins exceeds the threshold. The default is 5.
Event severity when successful logins exceed the threshold	Set the severity level, from 1 to 40, to indicate the importance of an event in which the number of successful logins exceeds the threshold. The default is 25.

19.67 MOHDevice

Use this Knowledge Script to monitor the number of active and available resources for Music on Hold (MOH) devices.

MOH resources are provided by software-based MOH servers that register with CallManager. MOH servers are configured through CallManager Administration. Each MOH server is capable of supplying up to 500 Unicast output streams and 204 Multicast streams simultaneously, and can be configured for up to 51 different audio sources.

19.67.1 Resource Object

CCM MOH device object

19.67.2 Default Schedule

By default, this script runs every five minutes.

19.67.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if threshold is breached?	Set to **y** to raise an event if a value exceeds or falls below a threshold. The default is y.
Collect data?	Set to **y** to collect data about MOH resources for reports and graphs. The default is n.
Event severity when threshold is breached	Set the severity level, from 1 to 40, to indicate the importance of an event in which a value exceeded or fell below a threshold. The default is 15.
Suppress event when Role is set to Backup?	Set to **y** to suppress event generation on CallManager resources whose role is set to "backup." The default is y. By suppressing event generation, you can run a script on all CallManager resources without raising an event on a resource that is not actively handling calls.
Threshold - Maximum active Multicast connections	Specify the maximum number of Multicast connections that can be active before an event is raised. The default is 25 connections.
Threshold - Maximum active Unicast connections	Specify the maximum number of Unicast connections that can be active before an event is raised. The default is 250 connections.
Threshold - Minimum available Multicast connections	Specify the minimum number of Multicast connections that must be available to prevent an event from being raised. The default is five connections.
Threshold - Minimum available Unicast connections	Specify the minimum number of Unicast connections that must be available to prevent an event from being raised. The default is 50 connections.

19.68 MOHServer

Use this Knowledge Script to monitor active and available streams for Music on Hold (MOH) servers.

MOH resources are provided by software-based MOH servers that register with CallManager. MOH servers are configured through CallManager Administration. Each MOH server is capable of supplying up to 500 Unicast output streams and 204 Multicast streams simultaneously, and can be configured for up to 51 different audio sources.

19.68.1 Resource Object

CCM MOH server

19.68.2 Default Schedule

By default, this script runs every five minutes.

19.68.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if threshold is breached?	Set to **y** to raise an event if a value exceeds or falls below a threshold. The default is y.
Collect data?	Set to **y** to collect data about MOH devices for reports and graphs. The default is n.
Event severity when threshold is breached	Set the severity level, from 1 to 40, to indicate the importance of an event in which a value exceeded or fell below a threshold. The default is 15.
Threshold - Maximum active audio sources	Specify the maximum number of audio sources for the MOH server that can be active before an event is raised. The default is 25 sources.
Threshold - Maximum active Music On Hold streams	Specify the maximum number of MOH streams that can be active before an event is raised. The default is 200 streams.
Threshold - Minimum available Music On Hold streams	Specify the minimum number of MOH streams that must be available to prevent an event from being raised. The default is 50 streams.

19.69 MOHServer_LostConnections

Use this Knowledge Script to monitor the number of times that a Music on Hold (MOH) server lost connection with a CallManager.

MOH resources are provided by software-based MOH servers that register with CallManager. MOH servers are configured through CallManager Administration. Each MOH server is capable of supplying up to 500 Unicast output streams and 204 Multicast streams simultaneously, and can be configured for up to 51 different audio sources.

19.69.1 Resource Object

CCM MOH server

19.69.2 Default Schedule

By default, this script runs every five minutes.

19.69.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if lost connections exceed the threshold?	Set to **y** to raise an event if the number of lost connections exceeds the threshold. The default is y.
Collect data?	Set to **y** to collect data about lost connections for reports and graphs. The default is n.
Event severity when lost connections exceed the threshold	Set the severity level, from 1 to 40, to indicate the importance of the event. The default is 10.
Threshold - Maximum lost connections	Specify the maximum number of lost connections that can occur before an event is raised. The default is 0 connections.

19.70 MTP_Device

Use this Knowledge Script to monitor the number of active and available resources for an individual MTP (media termination point) device. This script also monitors whether the MTP device ran out of resources at any time during the specified interval.

19.70.1 Resource Object

CCM MTP device object

19.70.2 Default Schedule

By default, this script runs every 15 minutes.

19.70.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if threshold is breached?	Set to **y** to raise an event if a value exceeds or falls below a threshold. The default is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default is n. This script collects the number of active MTP resources.
Event severity when threshold is breached	Set the event severity level, from 1 to 40, to indicate the importance of an event in which a value exceeded or fell below a threshold. The default is 15.
Suppress event when Role is set to Backup?	Set to **y** to suppress event generation on CallManager resources whose role is set to "backup." The default is y. By suppressing event generation, you can run a script on all CallManager resources without raising an event on a CallManager in backup mode.
Threshold - Maximum active resources	Specify the maximum number of MTP resources that can be active before an event is raised. The default is 20 resources.
Threshold - Minimum available resources	Specify the minimum number of MTP resources that must be available to prevent an event from being raised. The default is 0 resources.
Event severity when MTP device was out of resources	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the MTP device ran out of resources at least once during the interval. Set to 0 to ignore an out-of-resource event. The default is 25. **NOTE:** The event message for the out-of-resources event contains the number of times that the device ran out of resources.

19.71 MTPActiveConnections

Use this Knowledge Script to monitor the number of active connections for a Media Termination Point (MTP). An MTP software device allows Cisco CallManager to extend supplementary services, such as hold and transfer, to calls routed through an H.323 endpoint or an H.323 gateway.

19.71.1 Resource Object

CCM Media Termination Point object

19.71.2 Default Schedule

By default, this script runs every 30 minutes.

19.71.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if threshold is exceeded?	Set to **y** to raise an event if the number of active connections exceeds the threshold. The default is y.
Collect data?	Set to **y** to collect data about active connections for reports and graphs. The default is n.
Threshold - Maximum active connections	Specify the maximum number of connections that can be active before an event is raised. The default is 20 connections.
Event severity when threshold is exceeded	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of active connections exceeds the threshold. The default is 25.

19.72 MTPActiveStreams

Use this Knowledge Script to monitor the number of active streams for a Media Termination Point (MTP). An MTP software device allows Cisco CallManager to extend supplementary services, such as hold and transfer, to calls routed through an H.323 endpoint or an H.323 gateway.

19.72.1 Resource Object

CCM Media Termination Point object

19.72.2 Default Schedule

By default, this script runs every 30 minutes.

19.72.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if threshold is exceeded?	Set to **y** to raise an event if the threshold is exceeded. The default is y.
Collect data?	Set to **y** to collect data about active streams for reports and graphs. The default is n.
Threshold - Maximum active streams	Specify the maximum number of streams that can be active before an event is raised. The default is 20 streams.
Event severity when threshold is exceeded	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the threshold is exceeded. The default is 25.

19.73 MTPAvailableStreams

Use this Knowledge Script to monitor the number of available streams for a Media Termination Point (MTP). An MTP software device allows Cisco CallManager to extend supplementary services, such as hold and transfer, to calls routed through an H.323 endpoint or an H.323 gateway.

19.73.1 Resource Object

CCM Media Termination Point object

19.73.2 Default Schedule

By default, this script runs every 30 minutes.

19.73.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if threshold is not met?	Set to **y** to raise an event if the number of available streams falls below the threshold. The default is y.
Collect data?	Set to **y** to collect data about available streams for reports and graphs. The default is n.
Suppress event when Role is set to Backup?	Set to **y** to suppress event generation on CallManager resources whose role is set to "backup." The default is y. By suppressing event generation, you can run a script on all CallManager resources without raising an event on a resource that is not actively handling calls.
Threshold - Minimum available streams	Specify the minimum number of streams that must be available to prevent an event from being raised. The default is 20.
Event severity when threshold is not met	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of available streams falls below the threshold. The default is 25.

19.74 MTPCompletedConnections

Use this Knowledge Script to monitor the number of connections completed during an interval for a Media Termination Point (MTP). If the number of completed connections exceeds the threshold, an event is raised. An MTP software device allows Cisco CallManager to extend supplementary services, such as hold and transfer, to calls routed through an H.323 endpoint or an H.323 gateway.

19.74.1 Resource Object

CCM Media Termination Point object

19.74.2 Default Schedule

By default, this script runs every 30 minutes.

19.74.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if threshold is exceeded?	Set to **y** to raise an event if the number of completed connections exceeds the threshold. The default is y.
Collect data?	Set to **y** to collect data about completed connections for reports and graphs. The default is n.
Threshold - Maximum completed connections	Specify the maximum number of connections that can be completed before an event is raised. The default is 20 connections.
Event severity when threshold is exceeded	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of completed connections exceeds the threshold. The default is 25.

19.75 MTPCompletedStreams

Use this Knowledge Script to monitor the number of streams on connections completed during an interval for a Media Termination Point (MTP). An MTP software device allows Cisco CallManager to extend supplementary services, such as hold and transfer, to calls routed through an H.323 endpoint or an H.323 gateway.

19.75.1 Resource Object

CCM Media Termination Point object

19.75.2 Default Schedule

By default, this script runs every 30 minutes.

19.75.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if threshold is exceeded?	Set to **y** to raise an event if the number of completed streams exceeds the threshold. The default is y.
Collect data?	Set to **y** to collect data about completed streams for reports and graphs. The default is n.
Threshold - Maximum completed streams	Specify the maximum number of streams that can be completed before an event is raised. The default is 20 streams.
Event severity when threshold is exceeded	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of completed streams exceeds the threshold. The default is 25.

19.76 MTPsActive

Use this Knowledge Script to monitor the number of active Media Termination Points (MTP). An MTP software device allows Cisco CallManager to extend supplementary services, such as hold and transfer, to calls routed through an H.323 endpoint or an H.323 gateway.

19.76.1 Resource Object

CCM Call Processor

19.76.2 Default Schedule

By default, this script runs every five minutes.

19.76.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if threshold is exceeded?	Set to **y** to raise an event if the number of active MTPs exceeds the threshold. The default is y.
Collect data?	Set to **y** to collect data about active MTPs for reports and graphs. The default is n.
Threshold - Maximum active Media Termination Points	Specify the maximum number of MTPS that can be active before an event is raised. The default is 50.
Event severity when threshold is exceeded	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of active MTPs exceeds the threshold. The default is 25.

19.77 MTPsAvailable

Use this Knowledge Script to monitor the number of Media Termination Points (MTP) available for use. An MTP software device allows Cisco CallManager to extend supplementary services, such as hold and transfer, to calls routed through an H.323 endpoint or an H.323 gateway.

19.77.1 Resource Object

CCM Call Processor

19.77.2 Default Schedule

By default, this script runs every five minutes.

19.77.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if threshold is not met?	Set to **y** to raise an event if the number of available MTPs falls below the threshold. The default is y.
Collect data?	Set to **y** to collect data about available MTPs for reports and graphs. The default is n.
Suppress event when Role is set to Backup?	Set to **y** to suppress event generation on CallManager resources whose role is set to "backup." The default is y. By suppressing event generation, you can run a script on all CallManager resources without raising an event on a resource that is not actively handling calls.
Threshold - Minimum available Media Termination Points	Specify the minimum number of MTPs that must be available to prevent an event from being raised. The default is 3.
Event severity when threshold is not met	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of available MTPs falls below the threshold. The default is 15.

19.78 MTPsUnavailable

Use this Knowledge Script to monitor the number of times during an interval that a Media Termination Point (MTP) allocation was requested when none was available. An MTP software device allows Cisco CallManager to extend supplementary services, such as hold and transfer, to calls routed through an H.323 endpoint or an H.323 gateway.

19.78.1 Resource Object

CCM Call Processor

19.78.2 Default Schedule

By default, this script runs every five minutes.

19.78.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if threshold is exceeded?	Set to **y** to raise an event if the number of out-of-resource instances exceeds the threshold. The default is y.
Collect data?	Set to **y** to collect data about resource unavailability for reports and graphs. The default is n.
Threshold - Maximum out-of-resource instances	Specify the maximum number of times that MTP resources can be unavailable before an event is raised. The default is 0.
Event severity if threshold is exceeded	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of out-of-resource instances exceeds the threshold. The default is 5.

19.79 MulticastConfActive

Use this Knowledge Script to monitor the number of active Multicast conferences. This script raises an event if the number of active conferences exceeds the threshold.

NOTE: This script supports only Cisco CallManager version 3.0.

19.79.1 Resource Object

CCM Call Processor

19.79.2 Default Schedule

By default, this script runs every five minutes.

19.79.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if threshold is exceeded?	Set to **y** to raise an event if the number of active Multicast conferences exceeds the threshold. The default is y.
Collect data?	Set to **y** to collect data about active conferences for reports and graphs. The default is n.
Threshold - Maximum active Multicast conferences	Specify the maximum number of Multicast conferences that can be active before an event is raised. The default is 50.
Event severity when threshold is exceeded	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of active Multicast conferences exceeds the threshold. The default is 25.

19.80 MulticastConfAvailable

Use this Knowledge Script to monitor the number of new Multicast conferences that can be started. This script raises an event if the number of available conferences is less than the threshold.

NOTE: This script supports only Cisco CallManager version 3.0.

19.80.1 Resource Object

CCM Call Processor

19.80.2 Default Schedule

By default, this script runs every five minutes.

19.80.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if threshold is not met?	Set to **y** to raise an event if the number of available Multicast conferences falls below the threshold. The default is y.
Collect data?	Set to **y** to collect data about available conferences for reports and graphs. The default is n.
Suppress event when Role is set to Backup?	Set to **y** to suppress event generation on CallManager resources whose role is set to "backup." The default is y. By suppressing event generation, you can run a script on all CallManager resources without raising an event on a resource that is not actively handling calls.
Threshold - Minimum available Multicast conferences	Specify the minimum number of Multicast conferences that must be available to prevent an event from being raised raised. The default is 3 conferences.
Event severity when threshold is not met	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of available Multicast conferences falls below the threshold. The default is 15.

19.81 MulticastConfCompleted

Use this Knowledge Script to monitor the number of Multicast conferences completed during an interval. This script raises an event if the number of completed conferences exceeds the threshold.

NOTE: This script supports only Cisco CallManager version 3.0.

19.81.1 Resource Object

CCM Call Processor

19.81.2 Default Schedule

By default, this script runs every 30 minutes.

19.81.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if threshold is exceeded?	Set to **y** to raise an event if the number of completed Multicast conferences exceeds the threshold. The default is y.
Collect data?	Set to **y** to collect data about completed conferences for reports and graphs. The default is n.
Threshold - Maximum completed Multicast conferences	Specify the maximum number of Multicast conferences that can be completed before an event is raised. The default is 50 conferences.
Event severity if threshold is exceeded	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of completed Multicast conferences exceeds the threshold. The default is 25.

19.82 MulticastConfPhones

Use this Knowledge Script to monitor the number of active Multicast participants. This script raises an event if the number of participants exceeds the threshold.

NOTE: This script supports only Cisco CallManager version 3.0.

19.82.1 Resource Object

CCM Call Processor

19.82.2 Default Schedule

By default, this script runs every five minutes.

19.82.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if threshold is exceeded?	Set to **y** to raise an event if the number of active Multicast participants exceeds the threshold. The default is y.
Collect data?	Set to **y** to collect data about Multicast participants for reports and graphs. The default is n.
Threshold - Maximum active Multicast participants	Specify the maximum number of Multicast participants that can be active before an event is raised. The default is 100 participants.
Event severity when threshold is exceeded	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of active Multicast participants exceeds the threshold. The default is 25.

19.83 MulticastConfUnavailable

Use this Knowledge Script to monitor the number of times during an interval that a Multicast conference was requested when none was available. This script raises an event if the threshold is exceeded.

NOTE: This script supports only Cisco CallManager version 3.0.

19.83.1 Resource Object

CCM Call Processor

19.83.2 Default Schedule

By default, this script runs every five minutes.

19.83.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if threshold is exceeded?	Set to **y** to raise an event if the number of out-of-resource instances exceeds the threshold. The default is y.
Collect data?	Set to **y** to collect data about unavailable resources for reports and graphs.The default is n.
Threshold - Maximum out-of-resource instances	Specify the maximum number of out-of-resource instances that can occur before an event is raised. The default is 0 instances.
Event severity when threshold is exceeded	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of out-of-resource instances exceeds the threshold. The default is 5.

19.84 QRTEvent

Use this Knowledge Script to monitor the log files of the Quality Reporting Tool (QRT). This script will start a diagnostic action and raise an event if a QRT request has been logged.

19.84.1 Resource Object

CCM parent object

19.84.2 Default Schedule

By default, this script runs every minute.

19.84.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Script Options	
QRT log file directory	Provide the file path to the QRT log file. The default is `C:\Program Files\Cisco\QRT`.
Maximum number of entries per event message	Specify the maximum number of entries that can be placed into a single event message. If more entries are found, a new event is raised. The default is five entries.
On first run, scan files modified in the last N minutes	Specify the number of minutes of previous activity through which the script will search the log file. For instance, if you enter 15, the script will search through the last 15 minutes of activity. The default is 30 minutes.
Monitor Quality Reporting Tool Log Entries	
Event Notification	
Raise event if new QRT log entry is found?	Select **Yes** to raise an event if a new QRT log entry is found. The default is Yes.
Event severity when new QRT log entry is found	Set the event severity level, from 1 to 40, to indicate the importance of an event in which a new log entry is found. The default is 5.
Data Collection	
Collect data for QRT log entries?	Select **Yes** to collect data about QRT log entries for reports and graphs. The default is unselected.

19.85 RegAnalogAccesses

Use this Knowledge Script to monitor the number of registered analog accesses. This script raises an event if the number of registered accesses exceeds the threshold.

19.85.1 Resource Object

CCM Call Processor

19.85.2 Default Schedule

By default, this script runs every 30 minutes.

19.85.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if threshold is exceeded?	Set to **y** to raise an event if the number of registered analog accesses exceeds the threshold. The default is y.
Collect data?	Set to **y** to collect data about registered analog accesses for reports and graphs. The default is n.
Threshold - Maximum registered analog accesses	Specify the maximum number of analog accesses that can be registered before an event is raised. The default is 50 accesses.
Event severity when threshold is exceeded	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of registered analog accesses exceeds the threshold. The default is 25.

19.86 RegCtiPorts

Use this Knowledge Script to monitor the number of CTI (Computer Telephony Interface) ports registered to the local CallManager.

A CTI port is a virtual device that can have one or more virtual lines. Software-based CallManager applications, such as SoftPhone, AutoAttendant, and IP Interactive Voice Response (IVR), can be configured to use CTI ports. You use the same CallManager Administration area to configure CTI ports that you use to configure phones. Because these virtual devices use up resources on the CallManager, you can use this script to monitor how many CTI ports are registered and to raise an event if this number exceeds a threshold you set.

This script queries the CallManager database for CTI ports.

19.86.1 Resource Object

CCM parent object

19.86.2 Default Schedule

By default, this script runs every 30 minutes.

19.86.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if registered CTI ports exceed the threshold?	Set to **y** to raise an event if the number of registered CTI ports exceeds the threshold. The default is y.
Collect data?	Set to **y** to collect data about registered CTI ports for reports and graphs. The default is n.
SQL username	Provide the user login account required to access the CallManager SQL Server database. Leave this field blank to accept the default Cisco login account: `CiscoCCMCDR`. If you have changed the default password for `CiscoCCMCDR`, or want to use a different login account, configure the login and password using AppManager Security Manager before running this script. On the SQL tab of Security Manager, provide the IP address or hostname of the CallManager **SQL Server** computer, as well as the **SQL Login Name** and **SQL Login password**.
Threshold - Maximum registered CTI ports	Specify the maximum number of ports that can be registered before an event is raised. The default is 200 ports.
Event severity when registered CTI ports exceed the threshold	Set the severity level, from 1 to 40, to indicate the importance of an event in which the number of registered CTI ports exceeds the threshold. The default is 25.

19.87 RegDigitalAccesses

Use this Knowledge Script to monitor the number of registered digital accesses. This script raises an event if the number of registered accesses exceeds the threshold.

NOTE: This script supports only Cisco CallManager version 3.0.

19.87.1 Resource Object

CCM Call Processor

19.87.2 Default Schedule

By default, this script runs every 30 minutes.

19.87.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if threshold is exceeded?	Set to **y** to raise an event if the number of registered digital accesses exceeds the threshold. The default is y.
Collect data?	Set to **y** to collect data about registered digital accesses for reports and graphs. The default is n.
Threshold - Maximum registered digital accesses	Specify the maximum number of digital accesses that can be registered before an event is raised. The default is 50 accesses.
Event severity when threshold is exceeded	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of registered digital accesses exceeds the threshold. The default is 25.

19.88 RegHardwarePhones

Use this Knowledge Script to monitor the number of registered hardware phones. This script raises an event if the number of registered hardware phones exceeds the threshold.

19.88.1 Resource Object

CCM Call Processor

19.88.2 Default Schedule

By default, this script runs every 30 minutes.

19.88.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if registered hardware phones exceed the threshold?	Set to **y** to raise an event if the number of registered hardware phones exceeds the threshold. The default is y.
Collect data?	Set to **y** to collect data about registered hardware phones for reports and graphs. The default is n.
Threshold - Maximum registered hardware phones	Specify the maximum number of hardware phones that can be registered before an event is raised. The default is 1000 phones.
Event severity when registered hardware phones exceed the threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of registered hardware phones exceeds the threshold. The default is 25.

19.89 RegMGCPGateways

Use this Knowledge Script to monitor the number of registered MGCP gateways. This script raises an event if the number of registered gateways falls below the threshold.

19.89.1 Resource Object

CCM Call Processor

19.89.2 Default Schedule

By default, this script runs every 30 minutes.

19.89.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if threshold is not met?	Set to **y** to raise an event if the number of registered MGCP gateways falls below the threshold. The default is y.
Collect data?	Set to **y** to collect data about registered MGCP gateways for reports and graphs. The default is n.
Suppress event when Role is set to Backup?	Set to **y** to suppress event generation on CallManager resources whose role is set to "backup." The default is y. By suppressing event generation, you can run a script on all CallManager resources without raising an event on a resource that is not actively handling calls.
Threshold - Minimum registered MGCP gateways	Specify the minimum number of MGCP gateways that must be registered to prevent an event from being raised. The default is 0 gateways.
Event severity when threshold is not met	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of registered MGCP gateways falls below the threshold. The default is 25.

19.90 RegOtherDevices

Use this Knowledge Script to monitor the number of registered station devices using the SCCP protocol (Skinny Protocol) that are not hardware phones, such as Cisco IP SoftPhones, Cisco uOne ports and Cisco Unity voice ports.

19.90.1 Resource Object

CCM Call Processor

19.90.2 Default Schedule

By default, this script runs every 30 minutes.

19.90.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if threshold is exceeded?	Set to **y** to raise an event if the number of registered “other” devices exceeds the threshold. The default is y.
Collect data?	Set to **y** to collect data about registered “other” devices for reports and graphs.
Threshold - Maximum registered “other” devices	Specify the maximum number of “other” devices that can be registered before an event is raised. The default is 50 devices. I
Event severity if threshold is exceeded	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of registered “other” devices exceeds the threshold. The default is 25.

19.91 Report_CallActivity

Use this Knowledge Script to summarize the call activity for a selected time range for all CallManagers in a CallManager view. This report displays the data collected by the CallActivity script.

This script is a member of a Recommended Knowledge Script Group. For more information, see "Recommended Knowledge Script Groups" on page 1057.

19.91.1 Resource Object

Report agent

19.91.2 Default Schedule

By default, this script runs once.

19.91.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Data Source	
Select data wizard	Select the data for your report by view, computer, or data group. The default is View.
Select Knowledge Script	Select the scripts that collected the data you want to use for the report. Select only those scripts that are applicable to this Report script.
Select time range	Select a **Specific** or **Sliding** date/time range from which the report should pull data. The default is Sliding.
Select peak weekday(s)	Select the days of the week to include in your report. The default is Sunday through Saturday.
Total by	Select the time period by which the data in your report is aggregated. The default is Hour.
Report Settings	
Include parameter help card?	Set to **y** to include a table in the report that lists parameter settings for the Report script. The default is y.
Include table?	Set to **y** to include a table of data stream values in the report. The default is y.
Include chart?	Set to **y** to include a chart of data stream values in the report. The default is y.
All data on a single chart?	Set to **y** to create a chart that displays all of the collected data. If you accept the default of **n**, the data is spread over several charts based on the following: • If you chose **Hour** in the "Total by" parameter, each chart will display a maximum of 48 data points. • If you chose **Day** in the "Total by" parameter, each chart will display a maximum of 14 data points.

Parameter	How to Set It
Select chart style	Define the graphic properties for the charts in your report. The default style is Bar.
Select output folder	Set parameters for the output folder. The default folder name is CiscoCallMgrCallActivity.
Add job ID to output folder name?	Set to **y** to append the job ID to the name of the output folder. The default is n. A job ID helps correlate a specific instance of a Report script with the corresponding report.
Select properties	Set miscellaneous report properties as desired. The default report name is Cisco CallManager Call Activity.
Add time stamp to title?	Set to **y** to append a time stamp to the title of the report, making each title unique. The default is n. The time stamp is made up of the date and time the report was generated. A time stamp lets you run consecutive iterations of the same report without overwriting previous output.
Event Notification	
Raise event if report succeeds?	Set to **y** to raise an event when the report is successfully generated. The default is y.
Event severity when report succeeds	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report is successfully generated. The default is 35.
Event severity when report has no data	Set the severity level, from 1 to 40, to indicate the importance of the event when the report contains no data. The default is 25.
Event severity when report fails	Set the severity level, from 1 to 40, to indicate the importance of the event when the report fails. The default is 5.

19.92 Report_CallQualityDailyAvg

Use this Knowledge Script to display information about key call quality factors: jitter, latency, and lost data. This script uses the data collected by the CallQuality script.

CallQualityDailyAvg summarizes by hour, and weights by the total number of calls for each measured interval. For example, if you select two days of data, the chart represents the weighted average of all calls in a given hour for both days.

When running this script, take into consideration the following factors:

- The CallQuality script monitors only the jitter, latency, and lost data as seen from the originator of the call.
- The CallQuality script pulls its data from the actual Cisco CallManager database. It is possible that when the Monitoring script reads information from the database, CallManager may not have completed all updates to the database.
- There is no overall call-quality metric.

NOTE: If you want to report on call quality as seen by the recipient of the call, include real-time call quality data, or display an overall call quality metric, NetIQ Corporation recommends that you license the AppManager for VoIP Quality module, which provides more robust call-quality reporting.

19.92.1 Resource Object

Report agent

19.92.2 Default Schedule

By default, this script runs once.

19.92.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Data Source	
Select Knowledge Script(s)	Select the scripts that collected the data you want to use for the report. Select only those scripts that are applicable to this Report script.
Select CallManager Publisher	Select the CallManager Publisher on which you ran the Knowledge Script that you selected in the previous parameter.
Select time range	Select a **Specific** or **Sliding** date/time range from which the report should pull data. The default is Sliding.
Chart Thresholds	
Threshold - Jitter	Specify the jitter threshold to display on the jitter charts in the report. The default is 0 milliseconds.

Parameter	How to Set It
Threshold - Latency	Specify the latency threshold to display on the latency charts in the report. The default is 0 milliseconds.
Threshold - Percent lost data	Specify the lost data threshold to display on the charts in the report. The default is 0%.
Report Settings	
Include charts?	Set to **y** to include a chart in the report. The default is y.
Include table?	Set to **y** to include a table of information in the report. The default is y.
Include parameter help card?	Set to **y** to include a table in the report that lists parameter settings for the Report script. The default is y.
Select output folder	Select the name and location of the folder in which the report will be output. The default folder name is CCMCallQualityDailyAvg.
Select properties	Set miscellaneous report properties as desired. The default report name is Cisco CallManager Call Quality Daily Average.
Select chart style	Select chart properties in the Chart Settings dialog box. The default style is Bar.
Event Notification	
Raise event if report succeeds?	Set to **y** to raise an event when the report is successfully generated. The default is y.
Event severity when report succeeds	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report is successfully generated. The default is 35.
Event severity when report has no data	Set the severity level, from 1 to 40, to indicate the importance of the event when the report contains no data. The default is 25.
Event severity when report fails	Set the severity level, from 1 to 40, to indicate the importance of the event when the report fails. The default is 5.

19.93 Report_CallsByHour

Use this Knowledge Script to summarize the active calls for all selected CallManagers in a selected time period.

This script is a member of a Recommended Knowledge Script Group. For more information, see "Recommended Knowledge Script Groups" on page 1057.

19.93.1 Resource Object

Report agent

19.93.2 Default Schedule

By default, this script runs once.

19.93.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Data Source	
Select computer(s)	Select the computers that you want to include in the report. You can select computers by category: View, Server Group, or Computer. The default is View.
Select Knowledge Script(s)	Select the scripts that collected the data you want to use for the report. Select only those scripts that are applicable to this Report script.
Select time range	Select a **Specific** or **Sliding** date/time range from which the report should pull data. The default is Sliding.
Report Settings	
Include parameter help card?	Set to **y** to include a table in the report that lists parameter settings for the Report script. The default is y.
Include charts?	Set to **y** to include a chart in the report. The default is y.
Include tables?	Set to **y** to include a table of information in the report. The default is y.
Select chart properties	Select a chart type. The default style is Bar.
Select output folder	Select the name and location of the folder in which the report will be output. The default folder name is CCMCallsByHour.
Select properties	Set miscellaneous report properties as desired. The default report name is Cisco CallManager Calls By Hour.
Add time stamp to title?	Set to **y** to append a time stamp to the title of the report, making each title unique. The default is n. The time stamp is made up of the date and time the report was generated. A time stamp lets you run consecutive iterations of the same report without overwriting previous output.

Parameter	How to Set It
Event Notification	
Raise event if report succeeds?	Set to **y** to raise an event when the report is successfully generated. The default is y.
Event severity when report succeeds	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report is successfully generated. The default is 35.
Event severity when report has no data	Set the severity level, from 1 to 40, to indicate the importance of the event when the report contains no data. The default is 25.
Event severity when report fails	Set the severity level, from 1 to 40, to indicate the importance of the event when the report fails. The default is 5.

19.94 Report_ClusterAvgValueByHr

Use this Knowledge Script to display the average values by hour of the data streams for a CallManager cluster that were collected by a Knowledge Script within a specified time range.

19.94.1 Resource Object

Report agent

19.94.2 Default Schedule

By default, this script runs once.

19.94.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Data source	
Select data wizard	Select the data for your report by view, computer, or data group.
Select the style	Select the style for the first page of the report: • By computer provides links to pages showing the data collected from individual computers (each page shows all the data streams collected from a single computer) • By data stream provides links to pages showing a side-by-side comparison of values for the same data stream collected from different computers • By computer and data stream provides links to pages showing a single data stream collected from a computer • By Knowledge Script provides links to pages showing all data streams collected by a script (each page shows all data streams collected from all computers on which the script has run) • All data streams on one page generates a report with all data on a single page
Select time range	Select a **Specific** or **Sliding** date/time range from which the report should pull data. The default is Sliding.
Select peak weekday(s)	Select the days of the week to include in your report. The default is Sunday through Saturday.
Aggregation interval	Select the time period by which the data in your report is aggregated. The default is 1 hour.
Report Settings	
Include parameter help card?	Set to **y** to include a table in the report that lists parameter settings for the Report script. The default is y.
Include table?	Set to **y** to include a table of data stream values in the report. The default is y.

Parameter	How to Set It
Include chart?	Set to **y** to include a chart of data stream values in the report. The default is y.
Select chart style	Define the graphic properties for the charts in your report. The default style is Bar_Stacked.
Select output folder	Set parameters for the output folder. The default folder name is ClusterAvgValueByHr.
Add job ID to output folder name?	Set to **y** to append the job ID to the name of the output folder. The default is n. A job ID helps correlate a specific instance of a Report script with the corresponding report.
Select properties	Set miscellaneous report properties as desired. The default report name is Cluster Average By Hour.
Add time stamp to title?	Set to **y** to append a time stamp to the title of the report, making each title unique. The default is n. The time stamp is made up of the date and time the report was generated. A time stamp lets you run consecutive iterations of the same report without overwriting previous output.
Event Notification	
Raise event if report succeeds?	Set to **y** to raise an event when the report is successfully generated. The default is y.
Event severity when report succeeds	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report is successfully generated. The default is 35.
Event severity when report has no data	Set the severity level, from 1 to 40, to indicate the importance of the event when the report contains no data. The default is 25.
Event severity when report fails	Set the severity level, from 1 to 40, to indicate the importance of the event when the report fails. The default is 5.

19.95 Report_ClusterAvgValueByMin

Use this Knowledge Script to display the average values by minute of the data streams collected for a CallManager cluster by a Knowledge Script within a specified time range.

19.95.1 Resource Object

Report agent

19.95.2 Default Schedule

By default, this script runs once.

19.95.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Data Source	
Select data wizard	Select the data for your report by view, computer, or data group.
Select the style	Select the style for the first page of the report: • By computer provides links to pages showing the data collected from individual computers (each page shows all the data streams collected from a single computer) • By data stream provides links to pages showing a side-by-side comparison of values for the same data stream collected from different computers • By computer and data stream provides links to pages showing a single data stream collected from a computer • By Knowledge Script provides links to pages showing all data streams collected by a script (each page shows all data streams collected from all computers on which the script has run) • All data streams on one page generates a report with all data on a single page
Select time range	Select a **Specific** or **Sliding** date/time range from which the report should pull data. The default is Sliding.
Select peak weekday(s)	Select the days of the week to include in your report. The default is Sunday through Saturday.
Aggregation interval	Select the time period by which the data in your report is aggregated. The default is 1 hour.
Report Settings	
Include parameter help card?	Set to **y** to include a table in the report that lists parameter settings for the Report script. The default is y.
Include table?	Set to **y** to include a table of data stream values in the report. The default is y.

Parameter	How to Set It
Include chart?	Set to **y** to include a chart of data stream values in the report. The default is y.
Select chart style	Define the graphic properties for the charts in your report. The default style is Bar_Stacked.
Select output folder	Set parameters for the output folder. The default folder name is ClusterAvgValueByMin.
Add job ID to output folder name?	Set to **y** to append the job ID to the name of the output folder. The default is n. A job ID helps correlate a specific instance of a Report script with the corresponding report.
Select properties	Set miscellaneous report properties as desired. The default report name is Cluster Average By Minute.
Add time stamp to title?	Set to **y** to append a time stamp to the title of the report, making each title unique. The default is n. The time stamp is made up of the date and time the report was generated. A time stamp lets you run consecutive iterations of the same report without overwriting previous output.
Event Notification	
Raise event if report succeeds?	Set to **y** to raise an event when the report is successfully generated. The default is y.
Event severity when report succeeds	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report is successfully generated. The default is 35.
Event severity when report has no data	Set the severity level, from 1 to 40, to indicate the importance of the event when the report contains no data. The default is 25.
Event severity when report fails	Set the severity level, from 1 to 40, to indicate the importance of the event when the report fails. The default is 5.

19.96 Report_ClusterGenCounter

Use this Knowledge Script to display a chart showing the average, maximum, and minimum values of each CallManager cluster data stream and the actual data values of each data stream over time.

19.96.1 Resource Object

Report agent

19.96.2 Default Schedule

By default, this script runs once.

19.96.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Data Source	
Select data wizard	Select the data for your report, either by view, computer, or data group.
Select the style	Select the style for the first page of the report: • By computer provides links to pages showing the data collected from individual computers (each page shows all the data streams collected from a single computer) • By data stream provides links to pages showing a side-by-side comparison of values for the same data stream collected from different computers • By computer and data stream provides links to pages showing a single data stream collected from a computer • By Knowledge Script provides links to pages showing all data streams collected by a script (each page shows all data streams collected from all computers on which the script has run) • All data streams on one page generates a report with all data on a single page
Select time range	Select a **Specific** or **Sliding** date/time range from which the report should pull data. The default is Sliding.
Select peak weekday(s)	Select the days of the week to include in your report. The default is Sunday through Saturday.
Maximum number of points per chart	Specify the maximum number of data points to include in the chart. The default is 200 points.
Select average, minimum, or maximum	Select the type of value you want to represent in your report. The default is AVG.
Report Settings	
Include parameter help card?	Set to **y** to include a table in the report that lists parameter settings for the Report script. The default is y.

Parameter	How to Set It
Include table?	Set to **y** to include a table of data stream values in the report. The default is y.
Include chart?	Set to **y** to include a chart of data stream values in the report. The default is y.
Select chart style	Define the graphic properties for the charts in your report. The default style is Bar_Stacked.
Select output folder	Set parameters for the output folder. The default folder name is ClusterGenCounter.
Add job ID to output folder name?	Set to **y** to append the job ID to the name of the output folder. The default is n. A job ID helps correlate a specific instance of a Report script with the corresponding report.
Select properties	Set miscellaneous report properties as desired. The default report name is Cluster General Counter.
Add time stamp to title?	Set to **y** to append a time stamp to the title of the report, making each title unique. The default is n. The time stamp is made up of the date and time the report was generated. A time stamp lets you run consecutive iterations of the same report without overwriting previous output.
Event Notification	
Raise event if report succeeds?	Set to **y** to raise an event when the report is successfully generated. The default is y.
Event severity when report succeeds	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report is successfully generated. The default is 35.
Event severity when report has no data	Set the severity level, from 1 to 40, to indicate the importance of the event when the report contains no data. The default is 25.
Event severity when report fails	Set the severity level, from 1 to 40, to indicate the importance of the event when the report fails. The default is 5.

19.97 Report_ClusterSystemUsage

Use this Knowledge Script to display the average CPU and memory usage per CallManager cluster within a specified time frame.

19.97.1 Resource Object

Report agent

19.97.2 Default Schedule

By default, this script runs once.

19.97.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Data source	
Select cluster	Select a view and CallManager cluster for your report.
Select Knowledge Script(s)	Select the scripts that collected the data you want to use for the report. Select only those scripts that are applicable to this Report script.
Select time range	Select a **Specific** or **Sliding** date/time range from which the report should pull data.
Charts	
Include CPU usage chart?	Set to **y** to include a chart that details the CPU usage for the selected cluster. The default is y.
Include physical memory chart?	Set to **y** to include a chart that details the memory usage for the selected cluster. The default is y.
Chart threshold - CPU usage	Specify the CPU percentage threshold to display on the charts in the report. The default is 0%.
Chart threshold - Physical memory	Specify the physical memory threshold (in KB) to display on the charts in the report. The default is 0 KB.
Select chart size	Select the size of the rendered chart. Choose from Large, Medium, and Small. The default is Medium.
Select chart color scheme	Select a color scheme template. The default is NetIQ1.
Report Settings	
Include parameter help card?	Set to **y** to include a table in the report that lists parameter settings for the Report script. The default is y.
Include table?	Set to **y** to include a table of information in the report. The default is y.
Select output folder	Select the name and location of the folder in which the report will be output. The default folder name is ClusterSystemUsage.

Parameter	How to Set It
Add job ID to output folder name?	Set to **y** to append the job ID to the name of the output folder. The default is n. A job ID helps correlate a specific instance of a Report script with the corresponding report.
Select properties	Set miscellaneous report properties as desired. The default report name is Cluster System Usage.
Add time stamp to title?	Set to **y** to append a time stamp to the title of the report, making each title unique. The default is n. The time stamp is made up of the date and time the report was generated. A time stamp lets you run consecutive iterations of the same report without overwriting previous output.
Event Notification	
Raise event if report succeeds?	Set to **y** to raise an event when the report is successfully generated. The default is y.
Event severity when report succeeds	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report is successfully generated. The default is 35.
Event severity when report has no data	Set the severity level, from 1 to 40, to indicate the importance of the event when the report contains no data. The default is 25.
Event severity when report fails	Set the severity level, from 1 to 40, to indicate the importance of the event when the report fails. The default is 5.

19.98 Report_MGCPChannelUsage

Use this Knowledge Script to display the average and maximum active channels for a particular MGCP PRI or T1-CAS Group within a specified time range. This report uses the data collected by the MGCP_PRI_Channels and MGCP_T1CAS_Channels scripts.

19.98.1 Resource Object

Report agent

19.98.2 Default Schedule

By default, this script runs once.

19.98.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Data Source	
Select device type	Select whether to report on PRI or T1-CAS devices.
Select Knowledge Script(s)	Select the scripts that collected the data you want to include in the report.
Select device groups	Select the MGCP PRI or T1-CAS Groups that you want to include in the report.
Select time range	Select a **Specific** or **Sliding** date/time range from which the report should pull data. The default is Sliding.
Select peak weekday(s)	Select the days of the week to include in your report. The default is Sunday through Saturday.
Aggregate by	Select the time period by which the data in your report is aggregated. The default is Hour.
Report Settings	
Include parameter card?	Set to **y** to include a table in the report that lists parameter settings for the Report script. The default is y.
Include charts?	Set to **y** to include a chart of data stream values in the report. The default is y.
Include tables?	Set to **y** to include a table of data stream values in the report. The default is y.
Select chart style for average values	Define the graphic properties of the charts in your report. The default style is Line.
Chart title	Provide a name for the chart in your report. The default title is Cisco CallManager MGCP Device Group Channel Usage.

Parameter	How to Set It
All data on a single chart?	Set to **y** to display all data points on a single chart. The default is n. If you set to n, up to 24 data points are displayed on a single chart when aggregating by hour and up to 14 data points are displayed when aggregating by day.
Select output folder	Select the name and location of the folder in which the report will be output. The default folder name is CiscoCallManager MGCPDeviceGroupChannelUsage.
Add job ID to output folder name?	Set to **y** to append the job ID to the name of the output folder. The default is n. A job ID helps correlate a specific instance of a Report script with the corresponding report.
Select properties	Set miscellaneous report properties as desired. The default report name is Cisco CallManager MGCP Device Group Channel Usage.
Add time stamp to title	Set to **y** to append a time stamp to the title of the report, making each title unique. The default is n. The time stamp is made up of the date and time the report was generated. A time stamp lets you run consecutive iterations of the same report without overwriting previous output.
Event Notification	
Raise event if report succeeds?	Set to **y** to raise an event when the report is successfully generated. The default is y.
Event severity when report succeeds	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report is successfully generated. The default is 35.
Event severity when report has no data	Set the severity level, from 1 to 40, to indicate the importance of the event when the report contains no data. The default is 25.
Event severity when report fails	Set the severity level, from 1 to 40, to indicate the importance of the event when the report fails. The default is 5.

19.99 Report_MGCPDeviceUtil

Use this Knowledge Script to display average outbound busy attempts and calls completed for a particular MGCP PRI, T1-CAS, FXO, or FXS device within a specified time range. This report uses the data collected by the following scripts:

- MGCP_PRI
- MGCP_T1CAS
- MGCP_FXO
- MGCP_FXS

19.99.1 Resource Object

Report agent

19.99.2 Default Schedule

By default, this script runs once.

19.99.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Data Source	
Select device type	Select whether to report on PRI, T1-CAS, FXO, or FXS devices.
Select Knowledge Script	Select the scripts that collected the data you want to include in the report.
Select device(s)	Select the PRI, T1-CAS, FXO, or FXS devices that you want to include in the report.
Select time range	Select a **Specific** or **Sliding** date/time range from which the report should pull data. The default is Sliding.
Select peak weekday(s)	Select the days of the week to include in your report. The default is Sunday through Saturday.
Aggregate by	Select the time period by which the data in your report is aggregated. The default is Hour.
Chart Settings	
Chart threshold - Completed calls	Specify the completed calls threshold value to display on the charts in the report. The default is 0.
Chart threshold - Outbound busy attempts	Specify the outbound busy attempts threshold value to display on the charts in the report. The default is 0.
Report Settings	

Parameter	How to Set It
Include parameter card?	Set to **y** to include a table in the report that lists parameter settings for the Report script. The default is y.
Include charts?	Set to **y** to include a chart of data stream values in the report. The default is y.
Include tables?	Set to **y** to include a table of data stream values in the report. The default is y.
Select chart style	Define the graphic properties of the charts in your report. The default style is Line.
Chart title	Provide a name for the chart in your report. The default title is Cisco CallManager MGCP Device Utilization.
All data on a single chart?	Set to **y** to display all data points on a single chart. The default is n. If you set to n, up to 24 data points are displayed on a single chart when aggregating by hour and up to 14 data points are displayed when aggregating by day.
Select output folder	Select the name and location of the folder in which the report will be output. The default folder name is CiscoCallManager MGCPDeviceUtil.
Add job ID to output folder name?	Set to **y** to append the job ID to the name of the output folder. The default is n. A job ID helps correlate a specific instance of a Report script with the corresponding report.
Select properties	Set miscellaneous report properties as desired. The default report name is Cisco CallManager MGCP Device Utilization.
Add time stamp to title	Set to **y** to append a time stamp to the title of the report, making each title unique. The default is n. The time stamp is made up of the date and time the report was generated. A time stamp lets you run consecutive iterations of the same report without overwriting previous output.
Event Notification	
Raise event if report succeeds?	Set to **y** to raise an event when the report is successfully generated. The default is y.
Event severity when report succeeds	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report is successfully generated. The default is 35.
Event severity when report has no data	Set the severity level, from 1 to 40, to indicate the importance of the event when the report contains no data. The default is 25.
Event severity when report fails	Set the severity level, from 1 to 40, to indicate the importance of the event when the report fails. The default is 5.

19.100 Report_MGCPGatewayUsage

Use this Knowledge Script to display the average number of active MGCP PRI and T1-CAS Voice Channels for a particular gateway within a specified time range. This report uses the data collected by the MGCP_Gateway_CCM31 script.

19.100.1 Resource Object

Report agent

19.100.2 Default Schedule

By default, this script runs once.

19.100.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Data Source	
Select Knowledge Script(s)	Select the scripts that collected the data you want to include in the report.
Select gateway(s)	Select the name of the MGCP gateways that you want to include in the report. You can include nor more than 10 gateways in a single report.
Select time range	Select a **Specific** or **Sliding** date/time range from which the report should pull data. The default is Sliding.
Select peak weekday(s)	Select the days of the week to include in your report. The default is Sunday through Saturday.
Aggregate by	Select the time period by which the data in your report is aggregated. The default is Hour.
Report Settings	
Include parameter card?	Set to **y** to include a table in the report that lists parameter settings for the Report script. The default is y.
Include charts?	Set to **y** to include a chart of data stream values in the report. The default is y.
Include tables?	Set to **y** to include a table of data stream values in the report. The default is y.
Select chart style	Define the graphic properties of the charts in your report. The default style is Line.
Chart title	Provide a name for the chart in your report. The default title is Cisco CallManager MGCP Gateway Usage.
All data on a single chart?	Set to **y** to display all data points on a single chart. The default is n. If you set to n, up to 24 data points are displayed on a single chart when aggregating by hour and up to 14 data points are displayed when aggregating by day.

Parameter	How to Set It
Select output folder	Select the name and location of the folder in which the report will be output. The default folder name is CiscoCallManager MGCPGatewayUsage.
Add job ID to output folder name?	Set to **y** to append the job ID to the name of the output folder. The default is n. A job ID helps correlate a specific instance of a Report script with the corresponding report.
Select properties	Set miscellaneous report properties as desired. The default report name is Cisco CallManager MGCP Gateway Usage.
Add time stamp to title	Set to **y** to append a time stamp to the title of the report, making each title unique. The default is n. The time stamp is made up of the date and time the report was generated. A time stamp lets you run consecutive iterations of the same report without overwriting previous output.
Event Notification	
Raise event if report succeeds?	Set to **y** to raise an event when the report is successfully generated. The default is y.
Event severity when report succeeds	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report is successfully generated. The default is 35.
Event severity when report has no data	Set the severity level, from 1 to 40, to indicate the importance of the event when the report contains no data. The default is 25.
Event severity when report fails	Set the severity level, from 1 to 40, to indicate the importance of the event when the report fails. The default is 5.

19.101 Report_ServicesAvailability

Use this Knowledge Script to summarize the availability (throughout the day) of the services most relevant to CallManager, for all CallManagers in a CallManager view. This report displays the data collected by the CCM_HealthCheck script.

This script is a member of a Recommended Knowledge Script Group. For more information, see "Recommended Knowledge Script Groups" on page 1057.

19.101.1 Resource Object

Report agent

19.101.2 Default Schedule

By default, this script runs once.

19.101.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Data Source	
Select data wizard	Select the data for your report, either by view, computer, or data group. The default is View.
Select Knowledge Script(s)	Select the scripts that collected the data you want to use for the report. Select only those scripts that are applicable to this Report script.
Select time range	Select a **Specific** or **Sliding** date/time range from which the report should pull data. The default is Sliding.
Report Settings	
Include parameter help card?	Set to **y** to include a table in the report that lists parameter settings for the Report script. The default is y.
Include table?	Set to **y** to include a table of data stream values in the report. The default is y.
Include chart?	Set to **y** to include a chart of data stream values in the report. The default is y.
Select chart style	Define the graphic properties for the charts in your report. The default style is Bar.
Select output folder	Set parameters for the output folder. The default folder name is CiscoCallMgrServicesAvailability.
Add job ID to output folder name?	Set to **y** to append the job ID to the name of the output folder. The default is n. A job ID helps correlate a specific instance of a Report script and the corresponding report.

Parameter	How to Set It
Select properties	Set miscellaneous report properties as desired. The default report name is Cisco CallManager Services Availability.
Add time stamp to title?	Set to **y** to append a time stamp to the title of the report, making each title unique. The default is n. The time stamp is made up of the date and time the report was generated. A time stamp lets you run consecutive iterations of the same report without overwriting previous output.
Event Notification	
Raise event if report succeeds?	Set to **y** to raise an event when the report is successfully generated. The default is y.
Event severity when report succeeds	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report is successfully generated. The default is 35.
Event severity when report has no data	Set the severity level, from 1 to 40, to indicate the importance of the event when the report contains no data. The default is 25.
Event severity when report fails	Set the severity level, from 1 to 40, to indicate the importance of the event when the report fails. The default is 5.

19.102 Report_SystemUsage

Use this Knowledge Script to display the processes that are using the most CPU and memory for a selected CallManager. The report can contain a table for top CPU usage, which will be displayed as a percentage averaged over the time interval, and another for top memory usage, which will be displayed in KB averaged over the time interval.

This script displays the data collected by the CCM_SystemUsage Knowledge Script.

This script is a member of a Recommended Knowledge Script Group. For more information, see "Recommended Knowledge Script Groups" on page 1057.

19.102.1 Resource Object

Report agent

19.102.2 Default Schedule

By default, this script runs once.

19.102.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Data Source	
Select data wizard	Select which computers to include in the report. You can select computers by category: View, Server Group, or Computer. The default is View.
Select Knowledge Script(s)	Select the scripts that collected the data you want to use for the report. Select only those scripts that are applicable to this Report script.
Select time range	Select a **Specific** or **Sliding** date/time range from which the report should pull data. The default is Sliding.
Charts	
Include CPU usage chart?	Set to **y** to include a chart that details the CPU usage for the selected cluster. The default is y.
Include memory usage chart?	Set to **y** to include a chart that details the memory usage for the selected cluster. The default is y.
Chart threshold - CPU usage	Specify the CPU percentage threshold to display on the charts in the report. The default is 0%.
Chart threshold - Memory usage	Specify the physical memory threshold (in KB) to display on the charts in the report. The default is 0 KB.
Select chart size	Select the size of the rendered chart. Choose from Large, Medium, and Small. The default is Medium.
Select chart color scheme	Select a color scheme template. The default is NetIQ1.

Parameter	How to Set It
Report Settings	
Include parameter help card?	Set to **y** to include a table in the report that lists parameter settings for the Report script. The default is y.
Include table?	Set to **y** to include a table of information in the report. The default is y.
Select output folder	Select the name and location of the folder in which the report will be output. The default folder name is CiscoCallMgrSystemUsage.
Add job ID to output folder name?	Set to **y** to append the job ID to the name of the output folder. The default is n. A job ID helps correlate a specific instance of a Report script with the corresponding report.
Select properties	Set miscellaneous report properties as desired. The default report name is Cisco CallManager System Usage.
Add time stamp to title?	Set to **y** to append a time stamp to the title of the report, making each title unique. The default is n. The time stamp is made up of the date and time the report was generated. A time stamp lets you run consecutive iterations of the same report without overwriting previous output.
Event Notification	
Raise event if report succeeds?	Set to **y** to raise an event when the report is successfully generated. The default is y.
Event severity when report succeeds	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report is successfully generated. The default is 35.
Event severity when report has no data	Set the severity level, from 1 to 40, to indicate the importance of the event when the report contains no data. The default is 25.
Event severity when report fails	Set the severity level, from 1 to 40, to indicate the importance of the event when the report fails. The default is 5.

19.103 SQL_Accessibility

Use this Knowledge Script to monitor SQL Server and database accessibility. This script raises an event if a SQL Server or a specified database is not accessible.

19.103.1 Resource Object

CCM SQL Server

19.103.2 Default Schedule

By default, this script runs every one hour.

19.103.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Collect data?	Set to **y** to collect data for reports and graphs. The default is n. If set to y, this script returns 100 if all specified databases are accessible, 50 if some of the specified databases are accessible and some are not, or 0 if none of the specified databases is accessible.
SQL login	Provide the user login account required to access the SQL Server database. Configure the login and password using AppManager Security Manager before running this script. On the SQL tab of Security Manager, provide the IP address or hostname of the **SQL Server** computer, as well as the **SQL Login Name** and **SQL Login password**.
Database name	Provide a comma-separated list of the database names you want to monitor. For example, enter `master,pubs,tempdb`. If you leave this field blank, the script checks access to all databases. The default name is master.
Timeout	Specify a timeout period in seconds. The timeout period is the number of seconds to wait for a response before retrying or determining the database is inaccessible. The default is 0 seconds. **NOTE:** This script continues waiting until it receives a response or the timeout is reached. During this waiting period, other jobs are blocked from execution. Therefore, limit your use of this parameter or keep the timeout period at a minimum for regular monitoring jobs. When you run this script to troubleshoot a particular problem and not a regularly scheduled interval for ongoing maintenance, you may want to adjust this parameter to allow a longer timeout period.

Parameter	How to Set It
Number of retries	Specify the number of times to try connecting to the database before determining the database is inaccessible. The default is 0. **NOTE:** This script continues waiting until it receives a response or has made the specified number of retry attempts. During this waiting period, other jobs are blocked from execution. Therefore, limit your use of this parameter or keep retry attempts at a minimum for regular monitoring jobs. When you run this script to troubleshoot a particular problem and not a regularly scheduled interval for ongoing maintenance, you may want to adjust this parameter to allow more retry attempts.
Event severity when SQL Server or database is inaccessible	Set the severity level, from 1 to 40, to indicate the importance of an event in which SQL Server or the database is inaccessible. The default is 5.

19.104 SQL_BlockedProcesses

Use this Knowledge Script to monitor the number of SQL processes that are blocked (queued) for longer than the period of time that you define. When the number of blocked processes is greater than the threshold, an event is raised.

19.104.1 Resource Object

CCM SQL Server

19.104.2 Default Schedule

By default, this script runs every one minute.

19.104.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if blocked processes exceed the threshold?	Set to **y** to raise an event if the number of blocked (queued) processes exceeds the threshold. The default is y.
Collect data?	Set to **y** to collect data about blocked processes for reports and graphs. The default is n.
SQL login	Provide the user login account required to access the SQL Server database. Configure the login and password using AppManager Security Manager before running this script. On the SQL tab of Security Manager, provide the IP address or hostname of the **SQL Server** computer, as well as the **SQL Login Name** and **SQL Login password**.
Blocked for duration	Specify the length of time that a process can be queued before it is considered a blocked process. The default is 500 milliseconds.
Threshold - Maximum blocked processes	Specify the maximum number of processes that can be blocked before an event is raised. The default is 5.
Number of blocked processes to display	Specify the number of processes to display in the Graph pane of the Operator Console. The default is 20.
Event severity when blocked processes exceed the threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 5.

19.105 SQL_CPUUtil

Use this Knowledge Script to monitor the percentage of CPU resources used by the `sqlservr` and `sqlagent` processes. If the SQL Server processes exceed the threshold you set, an event is raised.

19.105.1 Resource Object

CCM SQL Server

19.105.2 Default Schedule

By default, this script runs every 15 minutes.

19.105.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if CPU usage exceeds the threshold?	Set to **y** to raise an event if CPU usage exceeds the threshold. The default is y.
Collect data?	Set to **y** to collect data about CPU usage for reports and graphs. The default is n.
Event severity when CPU usage exceeds the threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which CPU usage exceeds the threshold. The default is 8.
Monitor the SQL Server process?	Set to **y** to monitor SQL Server. The default is y.
Threshold - Maximum CPU usage for SQL Server process	Specify the maximum amount of CPU resources that can be consumed by the SQL process before an event is raised. The default is 10%.
Monitor the SQL Agent process?	Set to y to monitor SQL Agent. The default is y.
Threshold - Maximum CPU usage for SQL Agent process	Specify the maximum amount of CPU resources that can be consumed by the SQL Agent process before an event is raised. The default is 10%.

19.106 SQL_DataGrowthRate

Use this Knowledge Script to monitor the data growth and shrink rates for all SQL Server databases. Growth and shrink rates are calculated by taking the difference of the data space utilization from the current interval from the data space utilization from the last interval. If these rates exceed the thresholds you set, an event is raised.

19.106.1 Resource Objects

CCM SQL Database folder

CCM SQL Database object

19.106.2 Default Schedule

By default, this script runs every one hour.

19.106.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Dynamically enumerate at each interval?	Set to **y** to dynamically enumerate databases at each monitoring interval. The default is y. Dynamic enumeration takes place only when the script runs on the Databases object, not when it runs on an individual database.
Exclude these objects	Provide a comma-separated list of the names of objects you want to exclude. For example, enter `master,model,mdb`. **NOTE:** If you are not dynamically enumerating databases, ignore this parameter.
Raise event if threshold is exceeded?	Set to **y** to raise an event if a threshold is exceeded. The default is y.
Collect data?	Set to **y** to collect data about growth and shrink rates for reports and graphs. The default is n.
SQL login	Provide the user login account required to access the SQL Server database. Configure the login and password using AppManager Security Manager before running this script. On the SQL tab of Security Manager, provide the IP address or hostname of the **SQL Server** computer, as well as the **SQL Login Name** and **SQL Login password**. **NOTE:** If you are monitoring SQL Server 7, you need to use a sysadmin role account. Only members of the `sysadmin` role can get file statistics on SQL Server 7.0.
Threshold - Maximum growth rate	Specify the maximum percentage of data growth that is allowed between the last and current interval before an event is raised. The default is 25%.

Parameter	How to Set It
Threshold - Maximum shrink rate	Specify the maximum percentage of data shrinkage that is allowed between the last and current interval before an event is raised. The default is 25%.
Event severity when threshold is exceeded	Set the event severity level, from 1 to 40, to indicate the importance of an event in which a threshold is exceeded. The default is 5.

19.107 SQL_DataSpace

Use this Knowledge Script to monitor the data space available and the percentage of data space being used for each database. This script raises an event if the available data space is lower or the percentage of data space used is higher than the threshold for any database.

You can set this script to discover new databases dynamically each time it runs. Discovering databases dynamically allows you to monitor data space for databases that have been added since running the SQL Discovery script and prevents you from attempting to monitor databases that have been dropped since discovery.

This script uses the `sysadmin` role account for SQL 7.0.

19.107.1 Resource Objects

CCM SQL Database folder

CCM SQL Database object

19.107.2 Default Schedule

By default, this script runs every one hour.

19.107.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Dynamically enumerate at each interval?	Set to **y** to dynamically enumerate databases at each monitoring interval. The default is y. Dynamic enumeration takes place only when the script runs on the Databases object, not when it runs on an individual database.
Exclude these objects	Provide a comma-separated list of the names of objects you want to exclude. For example: master,model,mdb **NOTE:** If you are not dynamically enumerating databases, ignore this parameter.
Raise event if threshold is breached?	Set to **y** to raise an event if a threshold is exceeded or not met. The default is y.
Collect data?	Set to y to collect data about available and used data space for reports and graphs. The default is n.

Parameter	How to Set It
SQL login	Provide the user login account required to access the SQL Server database. Configure the login and password using AppManager Security Manager before running this script. On the SQL tab of Security Manager, provide the IP address or hostname of the **SQL Server** computer, as well as the **SQL Login Name** and **SQL Login password**. **NOTE:** If you are monitoring SQL Server 7, you need to use a `sysadmin` role account. Only members of the sysadmin role can get file statistics on SQL Server 7.0.
Threshold - Minimum available space	Specify the minimum amount of disk space that must be available to prevent an event from being raised. The default is 0 MB. Enter **0** to ignore this threshold.
Threshold - Maximum used space	Specify the maximum percentage of data space that can be used before an event is raised. The default is 90%.
Event severity when threshold is breached	Set the event severity level, from 1 to 40, to indicate the importance of an event in which a threshold is exceeded or not met. The default is 5.

19.108 SQL_DBGrowthRate

Use this Knowledge Script to monitor database growth and shrink rates. Growth and shrink rates are calculated by taking the difference between the database space utilization from the current interval and the database space utilization from the last interval. If these rates exceed the thresholds you set, an event is raised.

This script is a member of a Recommended Knowledge Script Group. For more information, see "Recommended Knowledge Script Groups" on page 1057.

19.108.1 Resource Objects

CCM SQL Database folder

CCM SQL Database object

19.108.2 Default Schedule

By default, this script runs every one hour.

19.108.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Dynamically enumerate at each interval	Set to **y** to dynamically enumerate databases at each monitoring interval. The default is y. Dynamic enumeration takes place only when the script runs on the Database object, not when it runs on an individual database.
Exclude these objects	Provide a comma-separated list of the names of objects you do not want to monitor. For example: `master,model,mdb` **NOTE:** If you are not dynamically enumerating databases, ignore this parameter.
Raise event if threshold is exceeded?	Set to **y** to raise an event if a threshold is exceeded. The default is y.
Collect data?	Set to **y** to collect data about database growth and shrink rates for reports and graphs. The default is y.
SQL login	Provide the user login account required to access the SQL Server database. Configure the login and password using AppManager Security Manager before running this script. On the SQL tab of Security Manager, provide the IP address or hostname of the **SQL Server** computer, as well as the **SQL Login Name** and **SQL Login password**. **NOTE:** If you are monitoring SQL Server 7, you need to use a sysadmin role account. Only members of the sysadmin role can get file statistics on SQL Server 7.0.

Parameter	How to Set It
Update usage?	Set to **y** to have SQL Server recalculate the space usage. The default is n.
Threshold - Maximum growth rate	Specify the maximum percentage of database growth that is allowed between the last and current interval before an event is raised. The default is 25%.
Threshold - Maximum shrink rate	Specify the maximum percentage of database shrinkage that is allowed between the last and current interval before an event is raised. The default is 25%.
Event severity when threshold is exceeded	Set the severity level, from 1 to 40, to indicate the importance of an event in which a threshold is exceeded. The default is 5.

19.109 SQL_DbOption

Use this Knowledge Script to verify how SQL Server database options are set. You can select which options to check and whether to raise an event when an option is set (On) or not set (Off).

19.109.1 Resource Object

CCM SQL Database object

19.109.2 Default Schedule

By default, this script runs every one hour.

19.109.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event when option is on?	Set to **y** to raise an event when the specified options are set. The default is y.
Raise event when option is off?	Set to **y** to raise an event when the specified options are not set. The default is n.
Collect data?	Set to **y** to collect data for reports and graphs. If set to y, this script returns 100 if all of the specified options are on, 50 if some options are on, and 0 if no options are on. The default is n.
SQL login	Provide the user login account required to access the SQL Server database. Configure the login and password using AppManager Security Manager before running this script. On the SQL tab of Security Manager, provide the IP address or hostname of the **SQL Server** computer, as well as the **SQL Login Name** and **SQL Login password**.
Check all options?	Set to **y** to check all database options. The default is y.
Check ANSI null default option?	Set to **y** to check whether this option is on. When set, this database option controls whether database columns are null by default. The default is n.
Check ANSI nulls option?	Set to **y** to check whether this SQL Server 7.0 or 2000 option is on. When this database option is set to true, all comparisons to a null value evaluate to unknown. The default is n.
Check ANSI warnings option?	Set to **y** to check whether this SQL Server 7.0 or 2000 option is on. This database option controls whether errors or warnings are issued when conditions such as "divide by zero" occur. The default is n.
Check auto_close option?	Set to **y** to check whether this SQL Server 7.0 or 2000 option is on. When this database option is set to true, the database is shutdown cleanly and its resources are freed after the last user exits. The default is n.

Parameter	How to Set It
Check auto_create statistics option?	Set to **y** to check whether this SQL Server 7.0 or 2000 option is on. When this database option is set to true, statistics are automatically created on columns used in a predicate. The default is n.
Check auto_update_statistics option?	Set to **y** to check whether this SQL Server 7.0 or 2000 option is on. When this database option is set to true, existing statistics are automatically updated when the statistics become out-of-date. The default is n.
Check auto_shrink option?	Set to **y** to check whether this SQL Server 7.0 or 2000 option is on. When this database option is set to true, the database files are candidates for automatic periodic shrinking. The default is n.
Check concat null yields null option?	Set to **y** to check whether this SQL Server 7.0 or 2000 option is on. When this database option is set to true, if either operand in a concatenation operation is null, the result is null. The default is n.
Check cursor close on commit option?	Set to **y** to check whether this SQL Server 7.0 or 2000 option is on. When this database option is set to true, any cursors that are open when a transaction is committed or rolled back are closed. The default is n.
Check dbo use only option?	Set to **y** to check whether this option is on. This database option specifies that only the database owner can access the database. The default is n.
Check default to local cursor option?	Set to **y** to check whether this SQL Server 7.0 or 2000 option is on. This database option controls whether cursor declarations default to local. The default is n.
Check merge publish option?	Set to **y** to check whether this SQL Server 7.0 or 2000 option is on. This database option controls whether the database can be published for a merge replication. The default is n.
Check no chkpt on recovery option?	Set to **y** to check whether this option is on. When this database option is off, a checkpoint record is added to the database after a recovery/restart operation. The default is n. This option is applicable only for SQL Server 6.x.
Check offline option?	Set to **y** to check whether the database is configured for offline operation. The default is n.
Check published option?	Set to **y** to check whether the database is configured for publishing (replication). The default is n.
Check quoted identifier option?	Set to **y** to check whether this SQL Server 7.0 or 2000 option is on. This database option controls whether double quotation mark characters can be used to surround delimited identifiers. The default is n.
Check read only option?	Set to **y** to check whether this option is on. When set, this database option specifies that database records are read-only; data cannot be modified. The default is n.
Check recursive triggers option?	Set to **y** to check whether this SQL Server 7.0 or 2000 option is on. This database option enables the recursive firing of raises. The default is n.
Check select into/bulkcopy option?	Set to **y** to check whether this option is on. When set, this database option allows unlogged database transactions. The default is n.

Parameter	How to Set It
Check single user option?	Set to **y** to check whether this option is on. When set, this database option specifies that only one user can access the database at a time. The default is n.
Check subscribed option?	Set to **y** to check whether the database is configured as a subscriber database. The default is n.
Check torn page detection option?	Set to **y** to check whether this SQL Server 7.0 or 2000 option is on. This database option controls whether SQL Server detects incomplete pages. The default is n.
Check trunc. log on chkpt option?	Set to **y** to check whether this option is on. This database option controls whether the transaction log is truncated when the Checkpoint process runs. The default is n.
Event severity when option is on or off	Set the event severity level, from 1 to 40, to indicate the importance of an event in which a monitored option is on or off. The default is 5.

19.110 SQL_DBSpace

Use this Knowledge Script to monitor available database space and the percentage of database space being used for each database. Database space includes both data space and log space. If the available database space exceeds the maximum threshold or falls below the minimum threshold you set, an event is raised.

You can set this script to discover new databases dynamically each time it runs. Discovering databases dynamically allows you to monitor database space for databases that have been added since running the Discovery_SQL Knowledge Script and prevents you from attempting to monitor databases that have been dropped since discovery.

NOTE: Although this script discovers databases each time it runs, the new databases are not reflected in the TreeView pane.

This script uses the `sysadmin` role account for SQL 7.0.

19.110.1 Resource Objects

CCM SQL Database folder

CCM SQL Database object

19.110.2 Default Schedule

By default, this script runs every one hour.

19.110.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Dynamically enumerate at each interval	Set to **y** to dynamically enumerate databases at each monitoring interval. The default is y. Dynamic enumeration takes place only when the script runs on the Database object, not when it runs on an individual database.
Exclude these objects	Provide a comma-separated list of the names of objects you do not want to monitor. For example: `master,model,mdb` **NOTE:** If you are not dynamically enumerating databases, ignore this parameter.
Raise event if threshold is breached?	Set to **y** to raise an event if a threshold is exceeded or not met. The default is y.
Collect data?	Set to **y** to collect data about available and used database space for reports and graphs. The default is n.

Parameter	How to Set It
SQL login	Provide the user login account required to access the SQL Server database. Configure the login and password using AppManager Security Manager before running this script. On the SQL tab of Security Manager, provide the IP address or hostname of the **SQL Server** computer, as well as the **SQL Login Name** and **SQL Login password**.
Update usage?	Set to **y** to have SQL Server recalculate the space usage. The default is n.
Threshold - Minimum available database space	Specify the minimum amount of disk space that must be available for the database (including data space and log space) to prevent an event from being raised. The default is 0 MB.
Threshold - Maximum used database space	Enter the maximum percentage of database space that can be used before an event is raised. The default is 90%.
Event severity when threshold is breached	Set the event severity level, from 1 to 40, to indicate the importance of an event in which a threshold is exceeded or not met. The default is 5.

19.111 SQL_Errorlog

Use this Knowledge Script to monitor the SQL Server error logs (`Errorlog`, `Errorlog.*` in `\MSSQL\LOG`). In the first interval, this script sets a starting point for future scanning. It does not scan the existing entries in the logs, and therefore it does not return any results on the first scan. As it continues to run at the interval specified in the Schedule tab, this script scans the logs for any new entries created since the last time it checked. This script raises an event if the number of entries that match the Find criteria exceeds the threshold you set.

NOTE: In general, the detail message for the script contains details about the occurrences found. If the message is larger than 32KB, the data is saved in a file on the managed computer (`<NetIQ_Home>\log`, for example, `C:\NetIQ\bin\log`) and the detail message contains the truncated data. If you generate these log files, you should periodically remove the files when you are done with them.

19.111.1 Resource Object

CCM SQL Server

19.111.2 Default Schedule

By default, this script runs every one hour.

19.111.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if threshold is exceeded?	Set to **y** to raise an event if a threshold is exceeded. The default is y.
Collect data?	Set to **y** to collect data about log entries for reports and graphs. The default is n.
Case sensitive?	Set to **y** to match upper and lower case letters when checking for a match to the search string. The default is n.
Literal match?	Set to **y** if you only want to register a match when there is an exact match to the search string. If set to n, the log text containing any of the words in Find will be matched. For example, if you set this parameter to **y** and enter "foo bar" as the Find string, only lines containing "foo bar" are considered a match. If you set this parameter to n with the same string, any lines that contain "foo," "bar," or "foo bar" are considered a match. The default is n.
Find log text	Specify all or part of the text string you want to find. Separate multiple entries with a space. The default is deadlock.
Threshold - Maximum log text matches	Specify the maximum number of matching entries that can be found before an event is raised. If you accept the default of **0**, the first instance exceeds the threshold and raises an event.
Event severity when threshold is exceeded	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the threshold is exceeded. The default is 5.

19.112 SQL_LogGrowthRate

Use this Knowledge Script to monitor log growth and shrink rates for all SQL Server databases. Growth and shrink rates are calculated by taking the difference of the log space utilization from the current interval from the log space utilization from the last interval. This script raises an event if these rates exceed the thresholds you set.

19.112.1 Resource Objects

CCM SQL Database folder

CCM SQL Database object

19.112.2 Default Schedule

By default, this script runs every one hour.

19.112.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Dynamically enumerate at each interval	Set to **y** to dynamically enumerate databases at each monitoring interval. The default is y. Dynamic enumeration takes place only when the script runs on the Database object, not when it runs on an individual database.
Exclude these objects	Provide a comma-separated list of the names of objects you do not want to monitor. For example: `master,model,mdb` **NOTE:** If you are not dynamically enumerating databases, ignore this parameter.
Raise event if threshold is exceeded?	Set to **y** to raise an event if the growth or shrink rate exceeds its threshold. The default is y.
Collect data?	Set to **y** to collect data about growth and shrink rates for reports and graphs. The default is n.
SQL login	Provide the user login account required to access the SQL Server database. Configure the login and password using AppManager Security Manager before running this script. On the SQL tab of Security Manager, provide the IP address or hostname of the **SQL Server** computer, as well as the **SQL Login Name** and **SQL Login password**. **NOTE:** If you are monitoring SQL Server 7, you need to use a sysadmin role account. Only members of the sysadmin role can get file statistics on SQL Server 7.0.

Parameter	How to Set It
Threshold - Maximum growth rate	Specify the maximum percentage of log growth that is allowed between the last and current interval before an event is raised. The default is 25%.
Threshold - Maximum shrink rate	Specify the maximum percentage of log shrinkage that is allowed between the last and current interval before an event is raised. The default is 25%.
Event severity when threshold is exceeded	Set the event severity level, from 1 to 40, to indicate the importance of an event in which a threshold is exceeded. The default is 5.

19.113 SQL_LogSpace

Use this Knowledge Script to monitor a database's available log space and log space usage. If the available log space is lower or the percentage of log space used is higher than the threshold you set, an event is raised.

You can set this script to discover new databases dynamically each time it runs.

NOTE: Although this script discovers databases each time it runs, the new databases are not reflected in the TreeView pane.

This script uses the `sysadmin` role account for SQL 7.0.

19.113.1 Resource Objects

CCM SQL Database folder

CCM SQL Database object

19.113.2 Default Schedule

By default, this script runs every one hour.

19.113.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Dynamically enumerate at each interval	Set to **y** to dynamically enumerate databases at each monitoring interval. The default is y.
Exclude these objects	Provide a comma-separated list of the names of objects you do not want to monitor. For example: `master,model,mdb` **NOTE:** If you are not dynamically enumerating databases, ignore this parameter.
Raise event if threshold is breached?	Set to **y** to raise an event if a threshold is exceeded or not met. The default is y.
Collect data?	Set to **y** to collect data about used and available log space for reports and graphs. The default is n.
SQL login	Provide the user login account required to access the SQL Server database. Configure the login and password using AppManager Security Manager before running this script. On the SQL tab of Security Manager, provide the IP address or hostname of the **SQL Server** computer, as well as the **SQL Login Name** and **SQL Login password**.

Parameter	How to Set It
Threshold - Minimum available log space	Specify the minimum amount of log space that must be available to prevent an event from being raised. The default is 0 MB.
Threshold - Maximum used log space	Specify the maximum percentage of log space that can be used before an event is raised. The default is 90%.
Event severity when threshold is breached	Set the event severity level, from 1 to 40, to indicate the importance of an event in which a threshold is exceeded or not met. The default is 5.

19.114 SQL_MemUtil

Use this Knowledge Script to monitor the amount of memory that is used by SQL Server processes: `sqlservr` and `sqlagent`.

If using SQL Server 7.0 or 2000, you can use this script to monitor total server memory usage, number of free buffers, and memory usage.

If the amount of memory used by SQL Server exceeds the threshold you set, an event is raised.

19.114.1 Resource Object

CCM SQL Server

19.114.2 Default Schedule

By default, this script runs every 10 minutes.

19.114.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if threshold is exceeded?	Set to **y** to raise an event if a threshold is exceeded. The default is y.
Collect data?	Set to **y** to collect data about memory usage for reports and graphs. The default is n.
Threshold - Maximum process memory usage	Specify the maximum amount of memory that can be consumed by SQL Server before an event is raised. The default is 50000000 bytes.
Threshold - Maximum number of free buffers	Specify the maximum number of free buffers that can be in use before an event is raised. The default is 50 buffers.
Threshold - Maximum SQL Server memory usage	Specify the maximum amount of memory that can be in use by SQL Server and all related processes before an event is raised. The default is 30000000 bytes.
Event severity when threshold is exceeded	Set the severity level, from 1 to 40, to indicate the importance of an event in which a threshold is exceeded. The default is 5.

19.115 SQL_NearFileMaxSize

Use this Knowledge Script to monitor the size of all SQL Server database files. This script enables you to set a threshold for when a file is reaching its maximum size. If any database file size exceeds the threshold you set, an event is raised.

You can set this script to discover new databases dynamically each time it runs.

This script is a member of a Recommended Knowledge Script Group. For more information, see "Recommended Knowledge Script Groups" on page 1057.

NOTE: Although this script discovers databases each time it runs, the new databases are not reflected in the TreeView pane.

19.115.1 Resource Objects

CCM SQL DB File folder

CCM SQL DB File object

19.115.2 Default Schedule

By default, this script runs every 24 hours.

19.115.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Dynamically enumerate at each interval	Set to **y** to dynamically enumerate databases at each monitoring interval. The default is y.
Exclude these objects	Provide a comma-separated list of the names of objects you do not want to monitor. For example: `master,model,mdb` **NOTE:** If you are not dynamically enumerating databases, ignore this parameter.
Raise event if threshold is exceeded?	Set to **y** to raise an event if a file's size exceeds the threshold. The default is y.
Collect data?	Set to **y** to collect data about file size for reports and graphs. The default is n.
SQL login	Provide the user login account required to access the SQL Server database. Configure the login and password using AppManager Security Manager before running this script. On the SQL tab of Security Manager, provide the IP address or hostname of the **SQL Server** computer, as well as the **SQL Login Name** and **SQL Login password**.

Parameter	How to Set It
Threshold - Maximum file size	Specify the maximum size a database file can attain before an event is raised. The default is 500 MB.
Threshold - Maximum file size utilization	Specify the maximum percentage that a file can use of its maximum allowed size before an event is raised. The default is 90%.
Event severity when threshold is exceeded	Set the event severity level, from 1 to 40, to indicate the importance of an event in which a threshold is exceeded. The default is 5.

19.116 SQL_NearMaxConnect

Use this Knowledge Script to monitor the open connection usage of SQL Server. This script compares the current number of connections being used to the maximum number of connections configured for the server. This script raises an event if the used percentage (current connections/maximum connections) exceeds the threshold you set.

19.116.1 Resource Object

CCM SQL Server

19.116.2 Default Schedule

By default, this script runs every one hour.

19.116.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if used connections exceed the threshold?	Set to **y** to raise an event if the percentage of used connections exceeds the threshold. The default is y.
Collect data?	Set to **y** to collect data about connection usage for reports and graphs. The default is n.
SQL login	Provide the user login account required to access the SQL Server database. Configure the login and password using AppManager Security Manager before running this script. On the SQL tab of Security Manager, provide the IP address or hostname of the **SQL Server** computer, as well as the **SQL Login Name** and **SQL Login password**.
Threshold - Maximum used connections	Specify the maximum percentage of connections that can be in use before an event is raised. The default is 95%.
Event severity when used connections exceed the threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the percentage of used connections exceeds the threshold. The default is 5.

19.117 SQL_NearMaxLocks

Use this Knowledge Script to monitor the lock usage of SQL Server. This script compares the current number of locks being used to the maximum number of locks configured for the server. This script raises an event if the used percentage (current locks/maximum locks) exceeds the threshold you set.

19.117.1 Resource Object

CCM SQL Server

19.117.2 Default Schedule

By default, this script runs every one hour.

19.117.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if lock usage exceeds the threshold?	Set to **y** to raise an event if the percentage of used locks exceeds the threshold. The default is y.
Collect data?	Set to **y** to collect data about lock usage for reports and graphs. The default is n.
SQL login	Provide the user login account required to access the SQL Server database. Configure the login and password using AppManager Security Manager before running this script. On the SQL tab of Security Manager, provide the IP address or hostname of the **SQL Server** computer, as well as the **SQL Login Name** and **SQL Login password**.
Threshold - Maximum lock usage	Enter the maximum percentage of locks that can be in use before an event is raised. The default is 95%.
Event severity when lock usage exceeds the threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which lock usage exceeds the threshold. The default is 5.

19.118 SQL_NetError

Use this Knowledge Script to monitor SQL Server network errors. This script compares the number of packet errors that occurred between the current and previous monitoring interval. This script raises an event if the number of errors exceeds the threshold you set.

19.118.1 Resource Object

CCM SQL Server

19.118.2 Default Schedule

By default, this script runs every 10 minutes.

19.118.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if network errors exceed the threshold?	Set to **y** to raise an event if network errors exceed the threshold. The default is y.
Collect data?	Set to **y** to collect data about network errors for reports and graphs. The default is n.
SQL login	Provide the user login account required to access the SQL Server database. Configure the login and password using AppManager Security Manager before running this script. On the SQL tab of Security Manager, provide the IP address or hostname of the **SQL Server** computer, as well as the **SQL Login Name** and **SQL Login password**.
Threshold - Maximum network errors	Specify the maximum number of network errors allowed before an event is raised. The default is 0 errors.
Event severity when network errors exceed the threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of network errors exceeds the threshold. The default is 5.

19.119 SQL_RepTransactions

Use this Knowledge Script to monitor the number of transactions in the transaction log of the publication database that are marked for replication but have not yet been replicated. This script raises an event if the number of transactions exceeds the threshold you set.

This script is a member of a Recommended Knowledge Script Group. For more information, see "Recommended Knowledge Script Groups" on page 1057.

19.119.1 Resource Object

CCM SQL Server

19.119.2 Default Schedule

By default, this script runs every one hour.

19.119.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if pending transactions exceed the threshold?	Set to **y** to raise an event if the number of transactions awaiting replication exceeds the threshold. The default is y.
Collect data?	Set to **y** to collect data about pending transactions for reports and graphs. The default is n.
Threshold - Maximum pending transactions	Specify the maximum number of transactions that can be awaiting replication before an event is raised. The default is 1000 transactions.
Event severity when pending transactions exceed the threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of transactions awaiting replication exceeds the threshold. The default is 5.

19.120 SQL_RepTranSec

Use this Knowledge Script to monitor the number of transactions being replicated per second. This script raises an event if the number of transactions exceeds the threshold you set.

19.120.1 Resource Object

CCM SQL Server

19.120.2 Default Schedule

By default, this script runs every one hour.

19.120.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if replicated transactions exceed the threshold?	Set to **y** to raise an event if the number of transactions replicated per second exceeds the threshold. The default is y.
Collect data?	Set to **y** to collect data about replicated transactions for reports and graphs. The default is n.
Threshold - Maximum transactions replicated per second	Specify the maximum number of transactions that can be replicated per second before an event is raised. The default is 1000 transactions.
Event severity when replicated transactions exceed the threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of transactions replicated per second exceeds the threshold. The default is 5.

19.121 SQL_RestartServer

Use this Knowledge Script to restart SQL Server. This script raises an event if the server either successfully restarts or fails to restart.

To restart the SQL services, this script will also stop dependent CallManager services, such as Cisco Database Layer Monitor. These services will be automatically restarted.

19.121.1 Resource Object

CCM SQL Server

19.121.2 Default Schedule

By default, this script runs once.

19.121.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Wait N seconds before restarting	Specify the number of seconds to wait after the server is stopped before attempting to automatically restart the server. The default is five seconds.
Event severity when stop fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which AppManager cannot stop the server. The default is 5.
Event severity when restart fails	Set the severity level, from 1 to 40, to indicate the importance of event in which AppManager cannot restart the server. The default is 5.
Event severity when status of service is unavailable	Set the severity level, from 1 to 40, to indicate the importance of an event in which AppManager cannot determine the status of the server. The default is 10.
Event severity when stop succeeds	Set the severity level, from 1 to 40, to indicate the importance of an event in which AppManager successfully stops the server. The default is 25.
Event severity when restart succeeds	Set the severity level, from 1 to 40, to indicate the importance of an event in which AppManager successfully restarts the server. The default is 25.

19.122 SQL_ServerDown

Use this Knowledge Script to monitor the up/down status of SQL Server. If SQL Server is down, the script reports an event and, optionally, attempts to re-start SQL Server.

19.122.1 Resource Object

CCM SQL Server

19.122.2 Default Schedule

By default, this script runs every one hour.

19.122.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Auto-start SQL Server?	Set to **y** to automatically restart SQL Server if it is down. The default is y.
Event severity when auto-start fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which AppManager cannot start SQL Server. The default is 5.
Event severity when auto-start succeeds	Set the severity level, from 1 to 40, to indicate the importance of an event in which AppManager successfully starts SQL Server. The default is 25.
Event severity when auto-start is set to "n"	Set the severity level, from 1 to 40, to indicate the importance of an event in which SQL Server is down and auto-start is set to n. The default is 18.

19.123 SQL_ServerThroughput

Use this Knowledge Script to monitor SQL Server throughput by measuring the number of T-SQL batch requests executed per second and the number of physical page reads per second. This script raises an event if either threshold is exceeded.

19.123.1 Resource Object

CCM SQL Server

19.123.2 Default Schedule

By default, this script runs every five minutes.

19.123.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if threshold is exceeded?	Set to **y** to raise an event if a threshold is exceeded. The default is y.
Collect data?	Set to **y** to collect data about throughput for reports and graphs. The default is n.
Threshold - Maximum batch requests per second	Specify the maximum number of batch request transactions allowed per second before an event is raised. The default is 120 requests.
Threshold - Maximum page reads per second	Specify the maximum number of page reads allowed per second before an event is raised. The default is 100 page reads.
Event severity when threshold is exceeded	Set the event severity level, from 1 to 40, to indicate the importance of an event in which a threshold is exceeded. The default is 5.

19.124 SQL_TopIOUsers

Use this Knowledge Script to monitor the number of I/O read and write operations used by SQL Server users and their connections. This script raises an event if the number of operations exceeds the threshold. You can specify the number of top user connections to display in the detail event and data message.

The detail message includes user name, most recent SQL statements executed, spid, and the number of operations used by each user.

19.124.1 Resource Object

CCM SQL Server

19.124.2 Default Schedule

By default, this script runs every 30 minutes.

19.124.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if I/O operations exceed the threshold?	Set to **y** to raise an event if the number if I/O read and writer operations exceeds the threshold. The default is y.
Collect data?	Set to **y** to collect data about I/O operations for reports and graphs. The default is n.
SQL login	Provide the user login account required to access the SQL Server database. Configure the login and password using AppManager Security Manager before running this script. On the SQL tab of Security Manager, provide the IP address or hostname of the **SQL Server** computer, as well as the **SQL Login Name** and **SQL Login password**.
Display T-SQL?	Set to **y** to display the executing T-SQL in the detail message. The default is y. **NOTE:** The executing SQL statements are included in the detail message only when you use the sa login account.
Exclude these applications	Provide a comma-separated list of the names of applications you do not want to monitor. The default is SQLEXEC.
Number of top user connections to display	Specify the number of top user connections you want displayed in the detail message (event or data). Enter **0** if you want all user connections displayed. The default is 5 connections.
Threshold - Maximum I/O operations	Specify the maximum number of I/O operations allowed before an event is raised. The default is 9999999 operations. **NOTE:** This number represents the cumulative operations for a user connection.

Parameter	How to Set It
Event severity when I/O operations exceed the threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of I/O operations exceeds the threshold. The default is 5.

19.125 SQL_TopLockUsers

Use this Knowledge Script to monitor the total number of locks held by all SQL Server users and their connections. This script raises an event if the number of user locks held exceeds threshold you set.

19.125.1 Resource Object

CCM SQL Server

19.125.2 Default Schedule

By default, this script runs every 30 minutes.

19.125.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if held user locks exceeds the threshold?	Set to **y** to raise an event if the number of held user locks exceeds the threshold. The default is y.
Collect data?	Set to **y** to collect data about held locks for reports and graphs. The default is n.
SQL login	Provide the user login account required to access the SQL Server database. Configure the login and password using AppManager Security Manager before running this script. On the SQL tab of Security Manager, provide the IP address or hostname of the **SQL Server** computer, as well as the **SQL Login Name** and **SQL Login password**.
Display T-SQL?	Set to **y** to display the executing T-SQL in the detail message. The default is y. **NOTE:** The executing SQL statements are included in the detail message only when you use the sa login account.
Exclude these applications	Provide a comma-separated list of the names of applications you do not want to monitor. The default is SQLEXEC.
Threshold - Maximum held user locks	Specify the maximum number of user locks that can be held before an event is raised. The default is 1000 locks.
Number of top user connections to display	Specify the number of top user connections you want displayed in the detail message (event or data). Enter **0** if you want all user connections displayed. The default is five connections.
Event severity when held user locks exceed the threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of held user locks exceeds the threshold. The default is 5.

19.126 SQL_TopMemoryUsers

Use this Knowledge Script to monitor the memory that can be allocated to all SQL Server users and their connections in 2KB pages. This script raises an event if the total number of allocated pages exceeds the threshold you set.

19.126.1 Resource Object

CCM SQL Server

19.126.2 Default Schedule

By default, this script runs every 30 minutes.

19.126.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if allocated memory pages exceed the threshold?	Set to **y** to raise an event if the number of allocated memory pages exceeds the threshold. The default is y.
Collect data?	Set to **y** to collect data about allocated memory pages for reports and graphs. The default is n.
SQL login	Provide the user login account required to access the SQL Server database. Configure the login and password using AppManager Security Manager before running this script. On the SQL tab of Security Manager, provide the IP address or hostname of the **SQL Server** computer, as well as the **SQL Login Name** and **SQL Login password**.
Display T-SQL?	Set to **y** to display the executing T-SQL in the detail message. The default is y. **NOTE:** The executing SQL statements are included in the detail message only when you use the sa login account.
Exclude these applications	Provide a comma-separated list of the names of applications you do not want to monitor. The default is SQLEXEC.
Threshold - Maximum allocated memory pages	Specify the maximum number of 2-KB memory pages that can be allocated before an event is raised. The default is 15000 pages.
Number of top user connections to display	Specify the number of top user connections you want displayed in the detail message (event or data). Enter **0** if you want all user connections displayed. The default is five connections.
Event severity when allocated memory pages exceed the threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of allocated memory pages exceeds the threshold. The default is 5.

19.127 SQL_UserConnections

Use this Knowledge Script to monitor the total number of SQL Server user connections. This script raises an event if the total number of SQL Server user connections exceeds the threshold you set.

19.127.1 Resource Object

CCM SQL Server

19.127.2 Default Schedule

By default, this script runs every 30 minutes.

19.127.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if user connections exceed the threshold?	Set to **y** to raise an event if the number of SQL Server user connections exceeds the threshold. The default is y.
Collect data?	Set to **y** to collect data about SQL Server user connections for reports and graphs. The default is n.
SQL login	Provide the user login account required to access the SQL Server database. Configure the login and password using AppManager Security Manager before running this script. On the SQL tab of Security Manager, provide the IP address or hostname of the **SQL Server** computer, as well as the **SQL Login Name** and **SQL Login password**.
Threshold - Maximum user connections	Specify the maximum number of user connections allowed before an event is raised. The default is 100 connections.
Number of user connections to display	Specify the number of user connections you want displayed in the detail message (event or data). Enter **0** to display all user connections. The default is 20 connections.
Event severity when user connections exceed the threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of user connections exceeds the threshold. The default is 5.

19.128 StreamApplOCTLErr

Use this Knowledge Script to monitor the number of times during an interval that an IOCTL (input/output control) error was detected. This script raises an event if the number of IOCTL errors exceeds the threshold.

19.128.1 Resource Object

CCM VoIP Application object

19.128.2 Default Schedule

By default, this script runs every five minutes.

19.128.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if threshold is exceeded?	Set to **y** to raise an event if the number of detected errors exceeds the threshold. The default is y.
Collect data?	Set to **y** to collect data about IOCTL errors for graphs and reports. The default is n.
Threshold - Maximum IOCTL errors	Specify the maximum number of IOCTL errors that can be detected before an event is raised. The default is 0.
Event severity when threshold is exceeded	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of IOCTL errors exceeds the threshold. The default is 5.

19.129 StreamAppMissDDErr

Use this Knowledge Script to monitor the number of times during an interval that a missing device driver (DD) error was detected. This script raises an event if the number of missing driver errors exceeds the threshold.

19.129.1 Resource Object

CCM VoIP Application object

19.129.2 Default Schedule

By default, this script runs every five minutes.

19.129.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if threshold is exceeded?	Set to **y** to raise an event if the number of errors exceeds the threshold. The default is y.
Collect data?	Set to **y** to collect data about missing device driver errors for graphs and reports. The default is n.
Threshold - Maximum missing device driver errors	Specify the maximum number of missing device driver errors that can be detected before an event is raised. The default is 0.
Event severity when threshold is exceeded	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of errors exceeds the threshold. The default is 5.

19.130 TftpChangeNotify

Use this Knowledge Script to monitor the number of TFTP change notifications handled during an interval. This script raises an event if the number of change notifications exceeds the threshold.

19.130.1 Resource Object

CCM TFTP object

19.130.2 Default Schedule

By default, this script runs every 30 minutes.

19.130.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if threshold is exceeded?	Set to **y** to raise an event if the number of change notifications exceeds the threshold. The default is y.
Collect data?	Set to **y** to collect data about TFTP change notifications for graphs and reports. The default is n.
Threshold - Maximum TFTP change notifications	Specify the maximum number of TFTP change notifications that can be handled before an event is raised. The default is 10.
Event severity when threshold is exceeded	Set the severity level, from 1 to 40, to indicate the importance of an event in which the number of TFTP change notifications exceeds the threshold. The default is 25.

19.131 TftpErrors

Use this Knowledge Script to monitor the number of TFTP-related errors occurring during an interval. This script raise an event if a threshold is exceeded.

19.131.1 Resource Object

CCM TFTP object

19.131.2 Default Schedule

By default, this script runs every 30 minutes.

19.131.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if threshold is exceeded?	Set to **y** to raise an event if any threshold is exceeded. The default is y.
Collect data?	Set to **y** to collect data about TFTP-related errors for graphs and reports. The default is n.
Threshold - Maximum aborted requests	Specify the maximum number of aborted requests that can occur before an event is raised. The default is 0 requests.
Threshold - Maximum NOT FOUND errors	Specify the maximum number of NOT FOUND errors that can occur before an event is raised. The default is 0. A NOT FOUND error is returned when a device requests a configuration file or firmware load, but the requested file does not exist in the TFTPPath of the TFTP server. Each time this error is returned, the TFTP server updates its NOT FOUND counter in perfmon. This script checks the NOT FOUND counter and raises an event if the number of NOT FOUND errors that occurred during the interval exceeds the threshold.
Threshold - Maximum overflow errors	Specify the maximum number of overflow errors that can occur before an event is raised. The default is 0. Overflow occurs when the TFTP service rejects some TFTP requests because it has reached the maximum number of allowable client connections. Note Overflow also occurs when the TFTP service is rebuilding configuration files; the TFTP service denies all requests while rebuilding files. If you don't want to generate an for requests that were denied during file rebuilding, you may want to click on the Advance tab and set this script to generate an event only if the overflow threshold is exceeded twice within two job iterations or three times within three job iterations. If events are generated more than three times in a row, you may have an overflow problem that requires your attention.
Event severity when threshold is exceeded	Set the severity level, from 1 to 40, to indicate the importance of an event in which a threshold is exceeded. The default is 25.

19.132 TftpHeartBeat

Use this Knowledge Script to monitor the Cisco TFTP heartbeat. This script raises an event if the heartbeat stops or is too low. In addition, this script generates a data stream for TFTP heartbeat data.

This script is a member of a Recommended Knowledge Script Group. For more information, see "Recommended Knowledge Script Groups" on page 1057.

19.132.1 Resource Object

CCM TFTP object

19.132.2 Default Schedule

By default, this script runs every five minutes.

19.132.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if heartbeat stops or falls below the threshold?	Set to **y** to raise an event if the heartbeat stops or falls below the threshold. The default is y.
Collect data?	Set to **y** to collect data about the TFTP heartbeat for graphs and reports. The default is n.
Threshold - Minimum heartbeat	Specify the minimum heartbeat count that must occur to prevent an event from being raised. The default is 500.
Event severity when heartbeat falls below the threshold	Set the event severity level, from 1 to 40,to indicate the importance of an event in which the heartbeat falls below the threshold. The default is 20.
Event severity when heartbeat stops	Set the event severity level, from 1 to 40,to indicate the importance of an event in which the heartbeat stops. The default is 10.

19.133 TftpRequests

Use this Knowledge Script to monitor the number of TFTP requests handled during an interval. This number includes local requests that were successfully handled by the server, “NotFound” requests, and requests that were aborted or rejected by the TFTP server.

This script is a member of a Recommended Knowledge Script Group. For more information, see “Recommended Knowledge Script Groups” on page 1057.

19.133.1 Resource Object

CCM TFTP object

19.133.2 Default Schedule

By default, this script runs every 30 minutes.

19.133.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if threshold is exceeded?	Set to **y** to raise an event if the number of TFTP requests exceeds the threshold. The default is y.
Collect data?	Set to **y** to collect data about TFTP requests for graphs and reports. The default is n.
Threshold - Maximum TFTP requests	Specify the maximum number of TFTP requests that can be handled before an event is raised. The default is 100 requests.
Event severity when threshold is exceeded	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of TFTP requests exceeds the threshold. The default is 25.

19.134 TftpSegmentPctLost

Use this Knowledge Script to monitor the percentage of TFTP segments lost during an interval. This script raises an event if the percentage of lost segments exceeds the threshold.

19.134.1 Resource Object

CCM TFTP object

19.134.2 Default Schedule

By default, this script runs every five minutes.

19.134.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if threshold is exceeded?	Set to **y** to raise an event if the percentage of lost TFTP segments exceeds the threshold. The default is y.
Collect data?	Set to **y** to collect data about lost TFTP segments for graphs and reports. The default is n.
Threshold - Maximum lost segments	Specify the maximum percentage of lost segments that can occur before an event is raised. The default is 1%.
Event severity when threshold is exceeded	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the percentage of lost TFTP segments exceeds the threshold. The default is 15.

19.135 TftpSegmentsSent

Use this Knowledge Script to monitor the number of TFTP segments sent during an interval. This script raises an event if the number of sent segments exceeds the threshold.

19.135.1 Resource Object

CCM TFTP object

19.135.2 Default Schedule

By default, this script runs every 30 minutes.

19.135.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if threshold is exceeded?	Set to **y** to raise an event if the number of sent segments exceeds the threshold. The default is y.
Collect data?	Set to **y** to collect data about sent TFTP segments for graphs and reports. The default is n.
Threshold - Maximum sent TFTP segments	Specify the maximum number of TFTP segments that can be sent before an event is raised. The default is 100000 segments.
Event severity when threshold is exceeded	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of sent TFTP segments exceeds the threshold. The default is 25.

19.136 TraceArchive

Use this Knowledge Script to archive CallManager trace files to avoid losing files when tracing wraps.

This script archives files based on the "last modified time" of each file, rather than the individual trace date or time stamp within each file.

NOTE: This script may be CPU-intensive based on the number of trace files the CallManager has collected. NetIQ Corporation recommends using this script for debugging purposes only — it may affect call processing.

19.136.1 Resource Object

CCM parent object

19.136.2 Default Schedule

By default, this script runs every 30 minutes.

19.136.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Trace file directory	Provide the file path to the trace file. The default is `c:\program files\cisco\trace\ccm`.
Destination directory	Provide the file path of the archive file. The default is `c:\tracearchive`.
On first run, minutes to go back	Specify the number of minutes of previous activity through which the script will search for trace files. For instance, if you enter 15, the script will search through the last 15 minutes of activity. The default is 30 minutes. **NOTE:** Ensure that the time you set is smaller than the amount of time that it takes CallManager to wrap or begin overwriting files. CallManager's iteration time varies based on the trace output format, the debug tracing level, the maximum number of files, the maximum lines per file, and the maximum minutes per file specified within the CallManager Serviceability tool. The larger the call volume, the faster CallManager will fill the trace files.

19.137 TraceEvent

Use this Knowledge Script to scan CallManager trace files for entries that match a text string that you specify. This script raises an event when matching entries are found.

NOTE: This script may be CPU-intensive based on the number of trace files the CallManager has collected. NetIQ Corporation recommends using this script for debugging purposes only — it may affect call processing.

19.137.1 Resource Object

CCM parent object

19.137.2 Default Schedule

By default, this script runs every 30 minutes.

19.137.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if matching entries are found?	Set to **y** to raise an event if the trace files contain entries that match your text string. The default is y.
Collect data?	Set to **y** to collect data about trace file entries for reports and graphs. The default is n.
Trace file directory	Specify the file path to the trace file. The default is `c:\program files\cisco\trace\ccm`.
Search for this text	Specify the text string that you want to find in the trace files. The default is `error|warning|failed|unexpected`.
On first run, scan files modified in the last N minutes	Set this parameter to determine how many minutes to go back and check for modified files the first time you run this script. Subsequent searches begin where the previous one finished. For instance, if you enter 15, the script will check for files modified within the past 15 minutes. The default is 30 minutes.
Event severity when matching entries are found	Set the event severity level, from 1 to 40,to indicate the importance of the event. The default is 25.
Maximum entries per event message	Specify the maximum number of entries that can be placed into a single event message. If more entries are found, a new event is generated. The default is 100 entries.

19.138 Transcoder_Device

Use this Knowledge Script to monitor the number of active and available resources for an individual transcoder device. This script also monitors whether the transcoder device ran out of resources at any time during the specified interval.

19.138.1 Resource Object

CCM Transcoder Device object

19.138.2 Default Schedule

By default, this script runs daily every 15 minutes.

19.138.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if threshold is breached?	Set to **y** to raise an event if a threshold is exceeded or not met. The event message for an out-of-resource event contains the number of times that the device ran out of resources. The default is y.
Collect data?	Set to **y** to collect data about active and available resources for reports and graphs. The default is n.
Event severity when threshold is breached	Set the event severity level, from 1 to 40, to indicate the importance of an event in which a threshold is exceeded or not met. The default is 15.
Suppress event when Role is set to Backup?	Set to **y** to suppress event generation on CallManager resources whose role is set to "backup." The default is y. By suppressing event generation, you can run a script on all CallManager resources without raising an event on a resource that is not registered.
Threshold - Maximum active resources	Specify the maximum number of transcoder resources that can be active (in use) before an event is raised. The default is 20 resources.
Threshold - Minimum available resources	Specify the minimum number of transcoder resources that must be available to prevent an event from being raised. The default is 0 resources.
Event severity when transcoder device was out of resources	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the transcoder device ran out of resources at least once during the interval. Set to 0 to ignore an out-of-resource event. The default is 25.

19.139 TranscoderResources

A transcoder is a device that takes the output stream of one codec and transcodes (converts) it from one compression type to another compression type. In CallManager, the transcoders convert between the G.711, G.723, and G.729 codecs.

Cisco CallManager invokes a transcoder on behalf of endpoint devices when the two devices are using different codecs. When inserted into a call, the transcoder converts the data streams between the different codecs, enabling communication between them.

Use this Knowledge Script to monitor the transcoder performance counters:

- **TranscoderResourcesActive**. The total number of transcoders that are in use on all transcoder devices registered with this CallManager. A transcoder in use is one transcoder resource that has been allocated for use in a call.
- **TranscoderResourcesAvailable**. The total number of transcoders that are not in use and are available for allocation on all transcoder devices registered with this CallManager.

19.139.1 Resource Object

CCM Call Processor

19.139.2 Default Schedule

By default, this script runs every five minutes.

19.139.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if threshold is breached?	Set to **y** to raise an event if a threshold is exceeded or not met. The default is y.
Collect data?	Set to **y** to collect data about transcoder resources for reports and graphs. The default is n.
Suppress event when Role is set to Backup?	Set to **y** to suppress event generation on CallManager resources whose role is set to "backup." The default is y. By suppressing event generation, you can run a script on all CallManager resources without raising an event on a resource that is not actively handling calls.
