Filter by generic trap number	Provide a generic trap number to filter trap messages that use the same object identifier (OID) for more than one trap message. You usually do not need to filter for generic and specific trap message numbers if the OID is unique. If you leave this parameter blank, the script does not use a generic value to filter for events. The generic value of the OID is defined by the SNMP source agent. The filter string can contain criteria used to include entries, exclude entries, or both. Separate the include and exclude criteria with a colon (:). If you are specifying only include criteria, the colon is not necessary.
Event severity	Set the event severity level, from 1 to 40, to indicate the importance of an event in which trap messages match your search criteria. The default is 5. You can adjust the severity depending on which type of message you are checking for.

75.22 HWHPNICRestorScripted

Use this Knowledge Script to monitor the AppManager managed client computer for incoming SNMPv1 trap messages as they are received.

This Knowledge Script runs on HP Insight Manager resources only.

This Knowledge Script monitors HP ESX or ESXi hosts, using specific object identifiers: 18001 or 18005. This trap will be sent any time connectivity is restored to a logical adapter. The connectivity to a logical adapter occurs in one of the following conditions:

- When the physical adapter in a single adapter configuration returns to the OK condition
- When at least one physical adapter in a logical adapter group returns to the OK condition

Connectivity can be restored by replacing a faulty cable or by re-attaching a cable that was unplugged.

To enable this script to work properly, do **not** enable event collapsing in the **Advanced** tab of the job's Properties dialog box.

Use this script in conjunction with the HWHPNICLost Knowledge Script to monitor the logical adapter status on your HP ESX or ESXi hosts.

You can specify search criteria to filter for trap messages from SNMP-enabled applications and devices. When a trap message matches all of the search criteria, an AppManager event is raised. All trap messages that match the filtering criteria are returned in the event.

This script requires the Microsoft **SNMP Trap** service to be running on the managed client computer.

When you run this script, only new trap messages received by the managed client computer are monitored.

75.22.1 Resource Object

vCenter server

75.22.2 Default Schedule

The default interval for this script is **Asynchronous**. After you start the Knowledge Script, its job status appears as **Running**.

75.22.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event?	Select **Yes** to raise an event if the trap message matches all of the search criteria. The default is Yes.
Collect data?	Select **Yes** to collect data about connectivity status. By default, data is not collected.

Parameter	How to Set It
Filter by IP source address	Identify the trap message source you want to filter by specifying the Internet Protocol (IP) address of the SNMP source. Specify the IP address using “dot” notation. For example: `10.10.10.10` To filter trap messages from more than one IP address, separate each address with a comma, without any spaces. If you leave this parameter blank, the script does not use the IP address of the SNMP agent that sent the trap message to filter for events. The filter string can contain criteria used to include entries, exclude entries, or both. Separate the include and exclude criteria with a colon (:). If you are specifying only include criteria, the colon is not necessary.
Filter by generic trap number	Provide a generic trap number to filter trap messages that use the same object identifier (OID) for more than one trap message. You usually do not need to filter for generic and specific trap message numbers if the OID is unique. If you leave this parameter blank, the script does not use a generic value to filter for events. The generic value of the OID is defined by the SNMP source agent. The filter string can contain criteria used to include entries, exclude entries, or both. Separate the include and exclude criteria with a colon (:). If you are specifying only include criteria, the colon is not necessary.
Event severity	Set the event severity level, from 1 to 40, to indicate the importance of an event in which trap messages match your search criteria. The default is 5. You may want to adjust the severity depending on which type of message you are checking for.

75.23 HWLogicalDiskStatus

Use this Knowledge Script to monitor the state of the logical disk. This script uses the UDP port number to find the logical disk attached to the agent.

The text of an event message indicates the state:

- Failed, when more physical drives have failed than the fault tolerance mode of the logical drive can handle without data loss.
- Other, when the logical drive is in a state other than normal or failed.

NOTE: The VirtualCenter_HWLogicalDiskStatus Knowledge Script is not supported on hosts with ESX 4.0 installed.

75.23.1 Prerequisites

- Configure AppManager Security Manager with the information that provides SNMP access to vCenter hosts. For more information, see the "Installing AppManager for VMware vSphere" chapter of the management guide.
- This script queries the SNMP agent on individual ESX or ESXi servers and does not depend on vCenter services. If an SNMP port is not enabled by the firewall, run ConfigureHostTraffic to enable a port.

75.23.2 Resource Object

vSphere ESX or ESXi host

75.23.3 Default Schedule

By default, this script runs every **15 minutes**.

75.23.4 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Job Failure Notification	
Raise event if hardware is not responding?	Select **Yes** to raise an event if logical disks are not responding. The default is Yes.
Event severity when hardware is not responding	Set the event severity level, from 1 to 40, to indicate the importance of an event in which logical disks are not responding. The default is 15.
Raise event if hardware is not supported?	Select **Yes** to raise an event if logical disks are not supported, for example do not have SNMP installed, the host is not HP or Dell hardware, or ports are not enabled. The default is Yes.

Parameter	How to Set It
Event severity when hardware is not supported	Set the event severity level, from 1 to 40, to indicate the importance of an event in which logical disks are not being supported. The default is 15.
Event severity when HWLogicalDiskStatus job fails unexpectedly	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the HWLogicalDiskStatus job fails unexpectedly. The default is 5.
SNMP Settings	
SNMP port number	Specify the UDP port number to send the SNMP request at each SNMP device. The default value is 161.
SNMP retries	Set the number of retries to attempt if a timeout occurs on an SNMP request. The default is 2 retries.
SNMP timeout	Set the number of seconds to wait for a response before timing out an SNMP request. The default is 5 seconds.
Monitor Logical Disk Status	
Event Notification	
Raise event if logical disk status is "Ok?"	Select **Yes** to raise an event if the status of a logical disk is "Ok". The default is unselected.
Event severity when logical disk status is "Ok"	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the status of a logical disk is "Ok". The default is 25.
Raise event if logical disk status is "Degraded?"	Select **Yes** to raise an event if the status of a logical disk is "Degraded". The default is Yes.
Event severity when logical disk status is "Degraded"	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the status of a logical disk is "Degraded". The default is 15.
Raise event if logical disk status is "Failed" or "Failure?"	Select **Yes** to raise an event if the status of a logical disk is "Failed" or "Failure". The default is Yes.
Event severity when logical disk status is "Failed or "Failure"	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the status of a logical disk is "Failed" or "Failure". The default is 10.
Raise event if logical disk status is "Offline?"	Select **Yes** to raise an event if the status of a logical disk is "Offline". The default is Yes.
Event severity when logical disk status is "Offline"	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the status of a logical disk is "Offline". The default is 15.
Raise event if logical disk status is "Other?"	Select **Yes** to raise an event if the status of a logical disk is "Other". The default is Yes.
Event severity when logical disk status is "Other"	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the status of a logical disk is "Other". The default is 15.
Data Collection	
Collect data for disk status?	Select **Yes** to collect data for graphs and reports. When enabled, returns a data stream for each SNMP device/SNMP attribute pair. The default is Yes.

75.24 HWPhysicalDiskStatus

Use this Knowledge Script to monitor the state of the physical disk. This script uses the UDP port number to find the logical disk attached to the agent.

The text of an event message indicates the state:

- **Failed**, when the drive is in one of the following conditions that requires drive replacement: the drive is no longer operating, or the drive has a predictive failure error.
- **Other**, when the instrument agent does not recognize the drive. You may need to upgrade your instrument agent and driver software.

NOTE: The VirtualCenter_HWPhysicalDiskStatus Knowledge Script is not supported on hosts with ESX 4.0 installed.

75.24.1 Prerequisites

- Configure AppManager Security Manager with the information that provides SNMP access to vCenter hosts. For more information, see the "Installing AppManager for VMware vSphere" chapter of the management guide.
- This script queries the SNMP agent on individual ESX or ESXi servers and does not depend on vCenter services. If an SNMP is not enabled by the firewall, run ConfigureHostTraffic to enable a port.

75.24.2 Resource Object

vSphere ESX or ESXi host

75.24.3 Default Schedule

By default, this script runs every **15 minutes**.

75.24.4 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Job Failure Notification	
Raise event if hardware is not responding?	Select **Yes** to raise an event if physical disks are not responding. The default is Yes.
Event severity when hardware is not responding	Set the event severity level, from 1 to 40, to indicate the importance of an event in which physical disks are not responding. The default is 15.

Parameter	How to Set It
Raise event if hardware is not supported?	Select **Yes** to raise an event if physical disks are not supported, for example do not have SNMP installed, the host is not HP or Dell hardware, or ports are not enabled. The default is Yes.
Event severity when hardware is not supported	Set the event severity level, from 1 to 40, to indicate the importance of an event in which physical disks are not being supported. The default is 15.
Event severity when HWPhysicalDiskStatus job fails unexpectedly	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the HWPhysicalDiskStatus job fails unexpectedly. The default is 5.
SNMP Settings	
SNMP port number	Specify the UDP port number to send the SNMP request at each SNMP device. The default value is 161.
SNMP retries	Set the number of retries to attempt if a timeout occurs on an SNMP request. The default is 2 retries.
SNMP timeout	Set the number of seconds to wait for a response before timing out an SNMP request. The default is 5 seconds.
Monitor Physical Disk Status	
Event Notification	
Raise event if disk status is "Ok" or "Operational?"	Select **Yes** to raise an event if the status of a physical disk is "Ok" or "Operational". The default is unselected.
Event severity when disk status is "Ok" or "Operational"	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the status of a physical disk is "Ok" or "Operational". The default is 25.
Raise event if disk status is "Degraded?"	Select **Yes** to raise an event if the status of a physical disk is "Degraded". The default is Yes.
Event severity when disk status is "Degraded"	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the status of a physical disk is "Degraded". The default is 15.
Raise event if disk status is "Failed" or "Failure?"	Select **Yes** to raise an event if the status of a physical disk is "Failed" or "Failure". The default is Yes.
Event severity when disk status is "Failed or "Failure"	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the status of a physical disk is "Failed" or "Failure". The default is 10.
Raise event if disk status is "Offline?"	Select **Yes** to raise an event if the status of a physical disk is "Offline". The default is Yes.
Event severity when disk status is "Offline"	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the status of a physical disk is "Offline". The default is 15.
Raise event if disk status is "Recovering?"	Select **Yes** to raise an event if the status of a physical disk is "Recovering". The default is Yes.
Event severity when disk status is "Recovering"	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the status of a physical disk is "Recovering". The default is 15.
Raise event if disk status is "Removed?"	Select **Yes** to raise an event if the status of a physical disk is "Removed". The default is Yes.
Event severity when disk status is "Removed"	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the status of a physical disk is "Removed". The default is 15.
Raise event if disk status is "Other?"	Select **Yes** to raise an event if the status of a physical disk is "Other". The default is Yes.

Parameter	How to Set It
Event severity when disk status is “Other”	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the status of a physical disk is “Other”. The default is 15.
Data Collection	
Collect data for disk status?	Select **Yes** to collect data for graphs and reports. When enabled, returns a data stream for each SNMP device/SNMP attribute pair. The default is Yes.

75.25 HWPowerSupply

Use this Knowledge Script to monitor the state of the power supply devices in the system. This script uses the UDP port number to find the power supply device attached to the agent.

The text of an event message indicates the state:

- Failed, when a power supply component detects a condition that could permanently damage the system.
- Degraded, when a temperature sensor, fan or other power supply component is outside normal operating range.
- Other, when the status cannot be determined or is not present.

75.25.1 Prerequisites

- Configure AppManager Security Manager with the information that provides SNMP access to vCenter hosts. For more information, see the "Installing AppManager for VMware vSphere" chapter of the management guide.
- This script queries the SNMP agent on individual ESX or ESXi servers and does not depend on vCenter services. If an SNMP port is not enabled by the firewall, run ConfigureHostTraffic to enable a port.

75.25.2 Resource Object

vSphere ESX or ESXi host

75.25.3 Default Schedule

By default, this script runs every **15 minutes**.

75.25.4 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Job Failure Notification	
Raise event if hardware is not responding?	Select **Yes** to raise an event if power supply devices are not responding. The default is Yes.
Event severity when hardware is not responding	Set the event severity level, from 1 to 40, to indicate the importance of an event in which power supply devices are not responding. The default is 15.
Raise event if hardware is not supported?	Select **Yes** to raise an event if power supply devices are not supported, for example do not have SNMP installed, the host is not HP or Dell hardware, or ports are not enabled. The default is Yes.

Parameter	How to Set It
Event severity when hardware is not supported	Set the event severity level, from 1 to 40, to indicate the importance of an event in which power supply devices are not being supported. The default is 15.
Event severity when HWPowerSupply job fails unexpectedly	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the HWPowerSupply job fails unexpectedly. The default is 5.
SNMP Settings	
SNMP port number	Specify the UDP port number to send the SNMP request at each SNMP device. The default value is 161.
SNMP retries	Set the number of retries to attempt if a timeout occurs on an SNMP request. The default is 2 retries.
SNMP timeout	Set the number of seconds to wait for a response before timing out an SNMP request. The default is 5 seconds.
Monitor Power Supply Status	
Event Notification	
Raise event if device status is "Ok?"	Select **Yes** to raise an event if the status of a power supply device is "Ok". The default is unselected.
Event severity when device status is "Ok"	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the status of a power supply device is "Ok". The default is 25.
Raise event if device status is "Degraded?"	Select **Yes** to raise an event if the status of a power supply device is "Degraded". The default is Yes.
Event severity when device status is "Degraded"	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the status of a power supply device is "Degraded". The default is 15.
Raise event if device status is "Failed" or "Critical?"	Select **Yes** to raise an event if the status of a power supply device is "Failed" or "Critical". The default is Yes.
Event severity when device status is "Failed or "Critical"	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the status of a power supply device is "Failed" or "Critical". The default is 10.
Raise event if device status is "Unknown?"	Select **Yes** to raise an event if the status of a power supply device is "Unknown". The default is Yes.
Event severity when device status is "Unknown"	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the status of a power supply device is "Unknown". The default is 15.
Raise event if device status is "Other?"	Select **Yes** to raise an event if the status of a power supply device is "Other". The default is Yes.
Event severity when device status is "Other"	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the status of a power supply device is "Other". The default is 15.
Data Collection	
Collect data for power supply status?	Select **Yes** to collect data for graphs and reports. When enabled, returns a data stream for each SNMP device/SNMP attribute pair. The default is Yes.

75.26 HWThermalStatus

Use this Knowledge Script to monitor the state of thermal devices in a system. This script uses the UDP port number to find the thermal device attached to the agent.

The text of an event message indicates the state:

- Failed, when a power supply component detects a condition that could permanently damage the system.
- Degraded, when a temperature sensor, fan, or other power supply component is outside of normal operating range.
- Other, when the status could not be determined or is not present.

75.26.1 Prerequisites

- Configure AppManager Security Manager with the information that provides SNMP access to vCenter hosts. For more information, see the "Installing AppManager for VMware vSphere" chapter of the management guide.
- This script queries the SNMP agent on individual ESX or ESXi servers and does not depend on vCenter services. If an SNMP port is not enabled by the firewall, run ConfigureHostTraffic to enable a port.

75.26.2 Resource Object

vSphere ESX or ESXi host

75.26.3 Default Schedule

By default, this script runs every **15 minutes**.

75.26.4 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Job Failure Notification	
Raise event if hardware is not responding?	Select **Yes** to raise an event if thermal devices are not responding. The default is Yes.
Event severity when hardware is not responding	Set the event severity level, from 1 to 40, to indicate the importance of an event in which thermal devices are not responding. The default is 15.
Raise event if hardware is not supported?	Select **Yes** to raise an event if thermal devices are not supported, for example do not have SNMP installed, the host is not HP or Dell hardware, or ports are not enabled. The default is Yes.

Parameter	How to Set It
Event severity when hardware is not supported	Set the event severity level, from 1 to 40, to indicate the importance of an event in which thermal devices are not being supported. The default is 15.
Event severity when HWThermalStatus job fails unexpectedly	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the HWThermalStatus job fails unexpectedly. The default is 5.
SNMP Settings	
SNMP port number	Specify the UDP port number to send the SNMP request at each SNMP device. The default value is 161.
SNMP retries	Set the number of retries to attempt if a timeout occurs on an SNMP request. The default is 2 retries.
SNMP timeout	Set the number of seconds to wait for a response before timing out an SNMP request. The default is 5 seconds.
Monitor Thermal Device Status	
Event Notification	
Raise event if device status is "Ok" or "Normal?"	Select **Yes** to raise an event if the status of a thermal device is "Ok" or "Normal". The default is unselected.
Event severity when device status is "Ok" or "Normal"	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the status of a thermal device is "Ok" or "Normal". The default is 25.
Raise event if device status is "Degraded?"	Select **Yes** to raise an event if the status of a thermal device is "Degraded". The default is Yes.
Event severity when device status is "Degraded"	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the status of a thermal device is "Degraded". The default is 15.
Raise event if device status is "Failed?"	Select **Yes** to raise an event if the status of a thermal device is "Failed". The default is Yes.
Event severity when device status is "Failed"	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the status of a thermal device is "Failed". The default is 10.
Raise event if device status is "Unknown?"	Select **Yes** to raise an event if the status of a thermal device is "Unknown". The default is Yes.
Event severity when device status is "Unknown"	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the status of a thermal device is "Unknown". The default is 15.
Raise event if device status is "Other?"	Select **Yes** to raise an event if the status of a thermal device is "Other". The default is Yes.
Event severity when device status is "Other"	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the status of a thermal device is "Other". The default is 15.
Data Collection	
Collect data for thermal device status?	Select **Yes** to collect data for graphs and reports. When enabled, returns a data stream for each SNMP device/SNMP attribute pair. The default is Yes.

75.27 Inventory

Use this Knowledge Script to monitor if hosts and virtual machines are added, moved, or removed from vCenter, track configuration changes to hosts and virtual machines in vCenter, and monitor virtual machines that migrate to different hosts or move to different datastores, resource pools, or virtual appliances.

If an inventory change occurs, you can set the script to run a discovery, which allows the AppManager console to display the most current inventory of virtual machines and hosts in vCenter.

The Inventory script monitors changes in hosts, virtual machines, and container objects such as clusters, folders, datacenters, resource pools, and virtual applications (vApps). To ensure that the module updates objects such as datastores and datastore clusters that are not monitored by the Inventory script in the TreeView, schedule the Discovery_VirtualCenter Knowledge Script to run on a daily basis instead of just once. Running the Inventory script in conjunction with the Discovery_VirtualCenter script set to run daily ensures that the TreeView remains current.

If you are using AppManager 7.x and want to enable the inventory discovery options, use the VirtualMachineInventory Knowledge Script instead of this script. Because of the asynchronous nature of the VirtualCenter_Inventory script, an Inventory discovery could potentially run every time the script detects that a batch of changes have occurred on a host or virtual machine, which may result in inaccurate monitoring data for an environment that is frequently updated.

With AppManager 7.x, use the VirtualMachineInventory job to control the discovery options, and let the Inventory job handle event generation:

- For the Inventory script, set the *Perform a discovery operation if...* parameters to No, and set the *Raise event if...* parameters to Yes as needed.
- For the VirtualMachineInventory script, set the *Raise event when virtual machines...* parameters to No, and set the *Rediscover if virtual machines...* parameters to Yes as needed.

NOTE:

- The VirtualCenter_Inventory Knowledge Script is supported on vCenter 4.0 or later.
- The first time you run this script, you might experience a short delay as the script gathers inventory data for the job. Subsequent jobs will start more quickly after the first VirtualCenter_Inventory job finishes its initial configuration.
- If you restart vCenter or the vCenter service while you are running the VirtualCenter_Inventory script with one or more of its discovery parameters selected, such as *Perform a discovery operation if a host is added?*, the VirtualCenter_Inventory discovery process will fail.
- If you are running a VirtualCenter_Inventory job that has discovery enabled, the script might miss some inventory changes because the Inventory job was restarted. Changes will be lost because the cache was cleared. In this situation, after the job restarts, monitoring takes a few minutes to start again. To monitor new changes in the TreeView, use this script as a monitoring policy.

This script monitors host and virtual machine objects, as well as their child objects.

This script monitors the following host details:

1. The model, such as PowerEdge R710
2. The vendor, such as Dell
3. The product name, such as VMware ESXi
4. The product version, such as 5.0.0

5. The product build, such as 469512
6. Whether vMotion is enabled or disabled
7. The number of CPUs or CPU cores
8. The total speed of the host, in MHz
9. The number and size of all physical disks
10. The configured memory, in MB
11. The number of physical network interface cards, or NICs, including their MAC addresses and drivers

This script monitors the following virtual machine details:

1. Guest operating system name, such as Microsoft Windows 2003 Server (32-bit)
2. Location of the VM files on the datastore
3. Whether or not the VM is a template
4. The number of vCPUs
5. The configured memory, in MB
6. The number, name, size, and type of all vDisks
7. The number, name, and MAC address of all vNICs

75.27.1 Resource Objects

- vCenter servers
- Hosts
- Virtual machines

75.27.2 Default Schedule

The default interval for this script is **Asynchronous**. After you start the Knowledge Script, its job status appears as **Running**.

75.27.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Job Failure Notification	
Event severity when AppManager failed to log in	Set the event severity level, from 1 to 40, to indicate the importance of an event in which AppManager failed to log in to vCenter. The default is 5.

Parameter	How to Set It
Event severity when Inventory job fails unexpectedly	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the Inventory job fails unexpectedly. The default is 5.
Event severity when filter settings contain conflicts	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the filter settings contain conflicts. The default is 15.
Event severity when Inventory job has delayed start	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the Inventory job experiences a delayed start. The default is 25.
Additional Settings	
Raise event if changed object was already removed from vCenter?	Select **Yes** to raise an event if a changed object was already removed from vCenter. The default is unselected.
Event Details	
Event detail format	Select either **HTML Table** or **Plain Text** as the format for event detail. The default is HTML Table.
Discovery Options	**Important** If you are using this module with AppManager 7.x, the following *Perform a discovery operation if...* parameters should remain unselected. Use the VirtualMachineInventory script to enable discovery options with AppManager 7.x.
Host Options	
Perform a discovery operation if a host is added?	Select **Yes** to run a discovery operation to update the inventory whenever a host is added to vCenter. The default is unselected.
Perform a discovery operation if a host is removed?	Select **Yes** to run a discovery operation to update the inventory whenever a host is removed from vCenter. The default is unselected.
Perform a discovery operation if host details are changed?	Select **Yes** to run a discovery operation to update the inventory whenever the details for a host are changed in vCenter. The default is unselected.
Perform a discovery operation if a host is moved?	Select **Yes** to run a discovery operation to update the inventory whenever a host is moved in vCenter. The default is unselected.
Virtual Machine Options	
Perform a discovery operation if a virtual machine is added?	Select **Yes** to run a discovery operation to update the inventory whenever a virtual machine is added to vCenter. The default is unselected.
Perform a discovery operation if a virtual machine is removed?	Select **Yes** to run a discovery operation to update the inventory whenever a virtual machine is removed from vCenter. The default is unselected.
Perform a discovery operation if a virtual machine is renamed?	Select **Yes** to run a discovery operation to update the inventory whenever a virtual machine is renamed in vCenter. The default is unselected.
Perform a discovery operation if a virtual machine is migrated?	Select **Yes** to run a discovery operation to update the inventory whenever a virtual machine is migrated in vCenter. The default is unselected.
Perform a discovery operation if a virtual machine is moved?	Select **Yes** to run a discovery operation to update the inventory whenever a virtual machine is moved in vCenter. The default is unselected.

Parameter	How to Set It
Perform a discovery operation if virtual machine details are changed?	Select **Yes** to run a discovery operation to update the inventory whenever the details for a virtual machine, such as increasing memory for a virtual machine, are changed in vCenter. The default is unselected.
Raise event if Discovery succeeds?	Select **Yes** to raise an event if the discovery operation launched by the Inventory job succeeds. The default is Yes.
Event severity if Discovery succeeds	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the discovery operation launched by the Inventory job succeeds. The default is 25.
Raise event if Discovery fails?	Select Yes to raise an event if the discovery operation launched by the Inventory job fails. The default is Yes.
Event severity if Discovery fails	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the discovery operation launched by the Inventory job succeeds. The default is 5.
Monitor Hosts	
Event Notification	**Important** If you are using this module with AppManager 7.x and you want to monitor events, use the following event parameters instead of the event parameters in the VirtualMachineInventory script.
Raise event if host is added?	Select **Yes** to raise an event when a host is added. The default is Yes. **NOTE:** This script raises an event whenever a host is added, ignoring the options you selected on the Objects tab. In addition, filters do not apply to added hosts.
Event severity when host is added	Set the event severity level, from 1 to 40, to indicate the importance of an event in which a host is added. The default is 25.
Raise event if host is removed?	Select **Yes** to raise an event when a host is removed from vCenter. The default is Yes.
Event severity when host is removed	Set the event severity level, from 1 to 40, to indicate the importance of an event in which a host is removed from vCenter. The default is 15.
Raise event if host is moved?	Select **Yes** to raise an event when a host is moved in vCenter. The default is Yes.
Event severity when host is moved	Set the event severity level, from 1 to 40, to indicate the importance of an event in which a host is moved in vCenter. The default is 25.
Raise event if host details change?	Select **Yes** to raise an event when the details for a host are changed in vCenter. The default is Yes.
Event severity when host details change	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the details for a host are changed in vCenter. The default is 25.
Monitor Virtual Machines	
Event Notification	**Important** If you are using this module with AppManager 7.x and you want to monitor events, use the following event parameters instead of the event parameters in the VirtualMachineInventory script.
Raise event if virtual machine is added?	Select **Yes** to raise an event when a virtual machine is added in vCenter. The default is Yes. **NOTE:** This script raises an event whenever a virtual machine is added, ignoring the options you selected on the Objects tab. In addition, filters do not apply to added virtual machines.

Parameter	How to Set It
Event severity when virtual machine is added	Set the event severity level, from 1 to 40, to indicate the importance of an event in which a virtual machine is added in vCenter. The default is 25.
Raise event if virtual machine is removed?	Select **Yes** to raise an event when a virtual machine is removed from vCenter. The default is Yes.
Event severity when virtual machine is removed	Set the event severity level, from 1 to 40, to indicate the importance of an event in which a virtual machine is removed from vCenter. The default is 15.
Raise event if virtual machine is renamed?	Select **Yes** to raise an event when a virtual machine is renamed. The default is Yes.
Event severity when virtual machine is renamed	Set the event severity level, from 1 to 40, to indicate the importance of an event in which a virtual machine is renamed. The default is 25.
Raise event if virtual machine is moved?	Select **Yes** to raise an event when a virtual machine is moved in vCenter. The default is Yes.
Event severity when virtual machine is moved	Set the event severity level, from 1 to 40, to indicate the importance of an event in which a virtual machine is moved in vCenter. The default is 25.
Raise event if virtual machine is migrated?	Select **Yes** to raise an event when a virtual machine is migrated in vCenter. The default is Yes.
Event severity when virtual machine is migrated	Set the event severity level, from 1 to 40, to indicate the importance of an event in which a virtual machine is migrated in vCenter. The default is 25.
Raise event if virtual machine details change?	Select **Yes** to raise an event when virtual machine details change. The default is Yes.
Event severity when virtual machine details change	Set the event severity level, from 1 to 40, to indicate the importance of an event in which virtual machine details change. The default is 25.

75.28 ResourcePoolCPUUsage

Use this Knowledge Script to monitor CPU usage for the resource pool. This script raises an event when CPU usage exceeds the threshold. In addition, this script generates data streams for CPU usage in MHz. This script monitors and collects data for the following performance metric:

CPU usage - Sum of actively used virtual CPU of all powered on virtual machines in the resource pool.

NOTE: This script will not work with existing ResourcePoolCPUUsage jobs. As a result, you will need to start new ResourcePoolCPUUsage jobs after installing this release.

75.28.1 Prerequisite

To enable the Knowledge Script to collect accurate CPU usage data for a resource pool, set the following **Statistics Collection Intervals** appropriately in the vCenter Management Server Configuration:

- **Collection Frequency**: The interval duration in vCenter must be less than or equal to the AppManager job interval schedule. For example, if you run the VirtualCenter_ResourcePoolCPUUsage Knowledge Script at 15-minute intervals, the interval duration in vCenter must be less than or equal to 15 minutes.

For more information about setting the Interval Duration and Statistics Level the vCenter, see the VMware Virtual Infrastructure 3 documentation.

75.28.2 Resource Objects

- vSphere resource pool
- vSphere virtual appliance (vApp)

75.28.3 Default Schedule

By default, this script runs every **15 minutes**.

75.28.4 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Event Notification	
Raise event when CPU usage exceeds the threshold?	Select **Yes** to raise an event if CPU usage exceeds the threshold you set. The default is Yes.
Event severity when CPU usage exceeds the threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which CPU usage exceeds the threshold. The default is 15.

Parameter	How to Set It
Raise event when CPU metrics are not available?	Select **Yes** to raise an event if CPU metrics are not available. The default is Yes.
Event severity when CPU metrics are not available?	Set the event severity level, from 1 to 40, to indicate the importance of an event in which CPU metrics are not available. The default is 15.
Event severity when AppManager failed to get metrics	Set the event severity level, from 1 to 40, to indicate the importance of an event in which AppManager failed to retrieve metrics from vCenter. The default is 15.
Event severity when AppManager failed to log in	Set the event severity level, from 1 to 40, to indicate the importance of an event in which AppManager failed to log in to vCenter. The default is 5.
Event severity when ResourcePoolCPUUsage job fails unexpectedly	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the ResourcePoolCPUUsage job fails unexpectedly. The default is 5.
Data Collection	
Collect data for CPU usage?	Select **Yes** to collect data about CPU usage for charts and reports. The default is unselected.
Monitoring	
Maximum threshold for CPU usage	Specify the maximum amount of CPU usage that can occur before an event is raised. The default is 800 MHz.

75.29 ResourcePoolMemUsage

This script monitors memory metrics for the vSphere resource pool. It raises an event if a monitored metric exceeds the threshold you set. In addition, this script generates a data stream for percentage of memory used and the amount of memory balloon in megabytes per second. This script monitors and collects data for the following performance metrics:

- Memory active - Sum of active memory for all powered-on virtual machines in the resource pool.
- Memory balloon - The sum of values for all memory balloon values for all powered-on virtual machines in the resource pool.
- Memory consumed - Sum of all memory used by all powered-on virtual machines in the resource pool.
- Memory granted - Sum of all granted memory for all powered-on virtual machines in the resource pool.

NOTE: This script will not work with existing ResourcePoolMemUsage jobs. As a result, you will need to start new ResourcePoolMemUsage jobs after installing this release.

75.29.1 Prerequisite

To enable the Knowledge Script to collect accurate memory related data for a resource pool, set the following **Statistics Collection Intervals** appropriately in the vCenter Management Server Configuration:

- **Collection Frequency**: The interval duration in vCenter must be less than or equal to the AppManager job interval schedule. For example, if you run the VirtualCenter_ResourcePoolMemUsage Knowledge Script at 15-minute intervals, the interval duration in vCenter must be less than or equal to 15 minutes.

For more information about setting the Interval Duration and Statistics Level in the vCenter, see the VMware Virtual Infrastructure 3 documentation.

75.29.2 Resource Objects

- vSphere resource pool
- vSphere virtual appliance (vApp)

75.29.3 Default Schedule

By default, this script runs every **15 minutes**.

75.29.4 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Event Notification	
Raise event when memory active exceeds the threshold?	Select **Yes** to raise an event when memory active exceeds the threshold you set. The default is unselected.
Event severity when memory active exceeds the threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which memory active exceeds the threshold you set. The default is 15.
Raise event when memory balloon exceeds the threshold?	Select **Yes** to raise an event when memory balloon exceeds the threshold you set. The default is Yes.
Event severity when memory balloon exceeds the threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which memory balloon exceeds the threshold you set. The default is 15.
Raise event when memory consumed exceeds the threshold?	Select **Yes** to raise an event when memory consumed exceeds the threshold you set. The default is Yes.
Event severity when memory consumed exceeds the threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which memory consumed exceeds the threshold you set. The default is 15.
Raise event when memory granted exceeds the threshold?	Select **Yes** to raise an event when memory granted exceeds the threshold you set. The default is unselected.
Event severity when memory granted exceeds the threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which memory granted exceeds the threshold you set. The default is 15.
Raise event when memory usage exceeds the threshold?	Select **Yes** to raise an event when memory usage exceeds the threshold you set. The default is unselected.
Event severity when memory usage exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which memory usage exceeds the threshold you set. The default is 15.
Raise event when memory metrics are not available?	Select **Yes** to raise an event if memory metrics are not available. The default is Yes.
Event severity when memory metrics are not available?	Set the event severity level, from 1 to 40, to indicate the importance of an event in which memory metrics are not available. The default is 15.
Event severity when AppManager failed to get metrics	Set the event severity level, from 1 to 40, to indicate the importance of an event in which AppManager failed to retrieve metrics from vCenter. The default is 15.
Event severity when AppManager failed to log in	Set the event severity level, from 1 to 40, to indicate the importance of an event in which AppManager failed to log in to vCenter. The default is 5.
Event severity when ResourcePoolMemUsage job fails unexpectedly	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the ResourcePoolMemUsage job fails unexpectedly. The default is 5.
Data Collection	
Collect data for memory active?	Select **Yes** to collect data about memory active for charts and reports. The default is unselected.
Collect data for memory balloon?	Select **Yes** to collect data about memory balloon for charts and reports. The default is unselected.
Collect data for memory consumed?	Select **Yes** to collect data about memory consumed for charts and reports. The default is unselected.

Parameter	How to Set It
Collect data for memory granted?	Select **Yes** to collect data about memory granted for charts and reports. The default is unselected.
Collect data for memory usage?	Select **Yes** to collect data about memory usage for charts and reports. The default is unselected.
Monitoring	
Maximum threshold for memory active	Specify the maximum amount of memory active that can occur before an event is raised. The default is 1024 MB.
Maximum threshold for memory balloon	Specify the maximum amount of memory balloon that can occur before an event is raised. The default is 100 KB.
Maximum threshold for memory consumed	Specify the maximum amount of memory consumed that can occur before an event is raised. The default is 1024 MB.
Maximum threshold for memory granted	Specify the maximum amount of memory granted that can occur before an event is raised. The default is 1024 MB.
Maximum threshold for memory usage	Specify the maximum amount of memory usage that can occur before an event is raised. The default is 80 percent.

75.30 ResourcePoolStatus

Use this Knowledge Script to monitor the overall status of the resource pool. This script raises an event if the state of the resource pool changes to one of the following states:

- Inconsistent - One or more nodes in the tree has children whose reservations are greater than the node is configured to support.
- Overcommitted - The tree is consistent internally, but the root resource pool does not have the capacity to meet the reservation of its children.
- Undercommitted - Every node has a reservation greater than the sum of the reservations for its children. There is enough capacity at the root to satisfy all of the resources reserved by the children.

NOTE: This script will not work with existing ResourcePoolStatus jobs. As a result, you will need to start new ResourcePoolStatus jobs after installing this release.

75.30.1 Resource Object

- vSphere resource pool
- vSphere virtual appliance (vApp)

75.30.2 Default Schedule

By default, this script runs every **15 minutes**.

75.30.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Event Notification	
Raise event when resource pool state changes?	Select **Yes** to raise an event if the resource pool state changes to inconsistent, overcommitted, or undercommitted. The default is Yes.
Event severity when resource pool state inconsistent	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the resource pool state changes to inconsistent. The default is 5.
Event severity when resource pool state is overcommitted	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the resource pool state changes to overcommitted. The default is 15.
Event severity when Resource pool state is undercommitted	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the resource pool state changes to undercommitted. The default is 25.
Raise event when resource pool is removed?	Select **Yes** to raise an event if the resource pool is removed. The default is Yes.

Parameter	How to Set It
Event severity when resource pool is removed	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the resource pool is removed. The default is 15.
Event severity when AppManager failed to get metrics	Set the event severity level, from 1 to 40, to indicate the importance of an event in which AppManager failed to retrieve metrics from vCenter. The default is 15.
Event severity when AppManager failed to log in	Set the event severity level, from 1 to 40, to indicate the importance of an event in which AppManager failed to log in to vCenter. The default is 5.
Event severity when ResourcePoolStatus job fails unexpectedly	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the ResourcePoolStatus job fails unexpectedly. The default is 5.
Data Collection	
Collect data for status change?	Select **Yes** to collect data about resource pool status for charts and reports. The default is unselected. **NOTE:** When enabled, data collection returns 100 for undercommitted, 50 for overcommitted, and 0 for inconsistent.

75.31 ServiceHealthCheck

Use this Knowledge Script to monitor vCenter Server services, such as the vCenter Server Heartbeat service, the vCenter Collector service, and the vCenter Server service. This script raises an event if a service is not running. You can set this script to automatically attempt to start services that are not running.

NOTE: When you run this script on a proxy agent computer to remotely monitor vCenter, this script will not monitor the vCenter services or collect any data.

75.31.1 Resource Object

vCenter server

75.31.2 Default Schedule

By default, this script runs every **10 minutes**.

75.31.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Restart VMware Capacity Planner service	Select **Yes** to automatically start the VMware Capacity Planner service when it is not running. The default is unselected.
Restart VMware License Server service?	Select **Yes** to automatically start the VMware License Server service when it is not running. The default is unselected.
Restart VMware Mount Service for VirtualCenter service?	Select **Yes** to automatically start the VMware Mount Service for VirtualCenter service when it is not running. The default is Yes.
Restart VMware Syslog Collector service?	Select **Yes** to automatically start the VMware Syslog Collector service when it is not running. The default is Yes.
Restart VMware USB Arbitration service?	Select **Yes** to automatically start the USB Arbitration service when it is not running. The default is unselected.
Restart VMware Update Manager service?	Select **Yes** to automatically start the Update Manager service when it is not running. The default is Yes.
Restart VMware VirtualCenter Management Webservices service?	Select **Yes** to automatically start the VMware VirtualCenter Management Webservices service when it is not running. The default is Yes.
Restart VMware vCenter Collector service?	Select **Yes** to automatically start the VMware vCenter Collector service when it is not running. The default is unselected.
Restart VMware vCenter Converter service?	Select **Yes** to automatically start the VMware vCenter Converter service when it is not running. The default is Yes.
Restart VMware vCenter Orchestrator Configuration service?	Select **Yes** to automatically start the VMware Orchestrator Configuration service when it is not running. The default is unselected.

Parameter	How to Set It
Restart VMware vCenter Server Heartbeat service?	Select **Yes** to automatically start the VMware vCenter Server Heartbeat service when it is not running. The default is unselected.
Restart VMware vCenter Server service?	Select **Yes** to automatically start the VMware vCenter Server service when it is not running. The default is Yes.
Restart VMware vSphere Authentication Proxy Adapter service?	Select **Yes** to automatically start the VMware vSphere Authentication Proxy Adapter service when it is not running. The default is unselected.
Restart VMware vSphere Authentication Proxy service?	Select **Yes** to automatically start the VMware vSphere Authentication Proxy service when it is not running. The default is unselected.
Restart VMware vSphere Auto Deploy Waiter service?	Select **Yes** to automatically start the VMware vSphere Auto Deploy Waiter service when it is not running. The default is Yes.
Restart VMware vSphere Profile-Driven Storage service?	Select **Yes** to automatically start the VMware vSphere Profile-Driven Storage service when it is not running. The default is unselected.
Restart VMware vSphere Update Manager UFA service?	Select **Yes** to automatically start the VMware vSphere Update Manager UFA service when it is not running. The default is unselected.
Restart VMwareVCMSDS service?	Select **Yes** to automatically start the VMwareVCMSDS service when it is not running. The default is Yes.
Restart vCenter Inventory service?	Select **Yes** to automatically start the vCenter Inventory service when it is not running. The default is unselected.
Restart vSphere ESXi Dump Collector service?	Select **Yes** to automatically start the vSphere ESXi Dump Collector service when it is not running. The default is unselected.
Restart vSphere Web Client service?	Select **Yes** to automatically start the vSphere Web Client service when it is not running. The default is unselected.
Event severity when services restarted	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the vCenter Server services are restarted. The default is 25.
Event severity when services not installed	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the vCenter Server services are not installed. The default is 25.
Event severity when services not running	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the vCenter Server services are stopped. The default is 15.
Event severity when services unable to start	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the vCenter Server services are not able to start. The default is 5.

75.32 Tasks

Use this Knowledge Script to monitor a set of vCenter tasks. You can filter the tasks by vCenter entity type, task name, and task user name. This script raises an event when monitored task failures are detected. Use the Objects tab to define the resources you want to monitor.

A list of VirtualCenter_Tasks events with the same short event message will not display individual event details. By default, AppManager collapses event details based on the object and the short event message. If the short event message is the same for a series of events, the list of events will collapse. To view the individual event details, disable event collapsing for that specific Tasks job.

In some instances, a new vCenter task might not include data about the inventory entity associated with the task, such as the VM or the datastore. When this occurs, AppManager associates the task with the root vCenter object in the TreeView. To ensure that you receive events about vCenter tasks that do not contain inventory information, select **vCenter** for the *Select vCenter entity type* parameter.

Each event report shows the following information:

- Task name
- Target
- User name
- Time on the vCenter Server when the task completed
- Error message

NOTE: The first time you run this script, you may experience a short delay before actual monitoring begins. This delay is caused by the various initialization processes that must be carried out by the Tasks script.

75.32.1 Resource Objects

Run the Discovery_VirtualCenter Knowledge Script on the vSphere components you want to monitor before running this Knowledge Script. You can also monitor objects that the Discovery_VirtualCenter Knowledge Script does *not* discover, such as distributed virtual port groups and distributed virtual switches.

You can run this script on the following resource objects:

- vCenter server
- Clusters
- Datacenters
- Datastores (you cannot monitor folders under the Datastore object)
- Hosts
- Resource pools
- Virtual appliances (vApps)
- Virtual machines
- Folders (you can only monitor the folder objects found under the Host & Clusters parent folder in the TreeView pane)
- Distributed virtual port groups (not displayed in the TreeView pane)
- Distributed virtual switches (not displayed in the TreeView pane)
- Network (not displayed in the TreeView pane)
- VMware distributed virtual switch (not displayed in the TreeView pane)

75.32.2 Default Schedule

The default interval for this script is **Asynchronous**. After you start the Knowledge Script, its job status appears as **Running**.

75.32.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Job Failure Notification	
Event severity when AppManager failed to log in	Set the event severity level, from 1 to 40, to indicate the importance of an event in which AppManager failed to log in. The default is 5.
Event severity when Tasks job fails unexpectedly	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the Tasks job fails unexpectedly. The default is 5.
Event severity when filter settings contain conflicts	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the filter settings contain conflicts. The default is 15.
Additional Settings	
Event Details	
Event detail format	Select either **HTML Table** or **Plain Text** as the format for event detail. The default is HTML Table.
Monitor vCenter Task Failures	
Event Notification	
Raise event if vCenter task fails?	Select **Yes** to raise an event if a vCenter "error" event is detected. The default is Yes.
Event severity when vCenter task fails	Set the event severity level, from 1 to 40, to indicate the importance of an event in which a vCenter task fails. The default is 10.
Select vCenter entity type	Click **Browse [...]** to select the vCenter entity types you want to monitor. The default is *all* entity types: Cluster, Datacenter, Datastore, dvSwitchFolder, dvPortGroup, Folder, Host, Network, ResourcePool, vApp, vCenter, VirtualMachine, VMwaredvSwitch. Click **Browse [...]** to select the vCenter entity types you want to monitor. The default settings include these entity types: Cluster, Datacenter, Datastore, Folder, Host, ResourcePool, VirtualMachine. **NOTE:** To monitor a datastore cluster object, select vCenter for this parameter.
Task user name	If you want to raise events only for a specific user, provide the name of the vCenter user you want to monitor. If you do not enter a user name, AppManager raises events related to all users. This parameter is not case-sensitive. The asterisk (*) and (?) are acceptable wildcards. **NOTE:** You must enter at least a * for this script to run. Do not leave this parameter blank.

Parameter	How to Set It
Task name	If you want to raise events only for a specific task, provide the name of the vCenter task you want to monitor. If you do not enter a task name, AppManager raises events related to all tasks. This parameter is not case-sensitive. The asterisk (*) and (?) are acceptable wildcards. **NOTE:** You must enter at least a * for this script to run. Do not leave this parameter blank.

75.33 VirtualCenterCPUUsage

Use this Knowledge Script to monitor the CPU usage of the vCenter process and total CPU usage on the computer hosting the vCenter. This script raises an event when CPU usage exceeds the threshold you set. This script monitors and collects data for the following performance metric:

- CPU usage - Amount of actively used virtual CPU, as a percentage of total available CPU.

NOTE: When you run this script on a proxy agent computer to remotely monitor vCenter, this script will not monitor the vCenter services or collect any data.

75.33.1 Resource Object

vCenter server

75.33.2 Default Schedule

By default, this script runs every **10 minutes**.

75.33.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Event Notification	
Raise event when VirtualCenter CPU usage exceeds the threshold?	Select **Yes** to raise an event if vCenter CPU usage exceeds the threshold you set. The default is Yes.
Event severity when VirtualCenter CPU usage exceeds the threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which CPU usage for the vCenter process exceeds the threshold. The default is 15.
Raise event when total host CPU usage exceeds the threshold?	Select **Yes** to raise an event if total CPU usage on the host computer exceeds the threshold you set. The default is Yes.
Event severity when total host CPU usage exceeds the threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which total CPU usage on the host computer exceeds the threshold. The default is 15.
Event severity when VirtualCenter CPUUsage job fails unexpectedly	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the CPUUsage job fails unexpectedly. The default is 5.
Data Collection	
Collect data for VirtualCenter CPU usage?	Select **Yes** to collect data about vCenter CPU usage charts and reports. The default is unselected.
Collect data for total host CPU usage?	Select **Yes** to collect data about total CPU usage on the host for charts and reports. The default is unselected.
Monitoring	

Parameter	How to Set It
Maximum threshold for VirtualCenter CPU usage (%)	Specify the maximum amount of CPU usage that can occur for the vCenter process before an event is raised. The default is 60%.
Maximum threshold for total host CPU usage (%)	Specify the maximum amount of CPU usage that can occur on the host computer before an event is raised. The default is 95%.

75.34 VirtualCenterMemoryUsage

Use this Knowledge Script to monitor memory usage of the vCenter process and the total amount of memory being used on the server hosting vCenter. This script raises an event if the memory usage exceeds the threshold you set.

NOTE: When you run this script on a proxy agent computer to remotely monitor the vCenter, this script will not monitor the vCenter services or collect any data.

75.34.1 Resource Object

vCenter server

75.34.2 Default Schedule

By default, this script runs every **10 minutes**.

75.34.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Event Notification	
Raise event when memory usage exceeds the threshold?	Select **Yes** to raise an event if the percentage of cluster memory usage exceeds the threshold you set. The default is Yes.
Event severity when memory usage exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which memory usage exceeds the threshold. The default is 15.
Raise event when total host memory usage exceeds the threshold?	Select **Yes** to raise an event if total memory usage for the host computer exceeds the threshold you set. The default is Yes.
Event severity when total host memory usage exceeds the threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which total memory usage for the host computer exceeds the threshold. The default is 15.
Event severity when VirtualCenterMemoryUsage job fails unexpectedly	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the VirtualCenterMemoryUsage job fails unexpectedly. The default is 5.
Data Collection	
Collect data for VirtualCenter memory usage?	Select **Yes** to collect data about vCenter memory usage for charts and reports. The default is unselected.
Collect data for total host memory usage?	Select **Yes** to collect data about total memory usage on the host computer for charts and reports. The default is unselected.
Monitoring	
Maximum threshold for VirtualCenter memory usage (KB)	Specify the maximum amount of memory usage that can occur for the vCenter process before an event is raised. The default is 20000 kilobytes.

Parameter	How to Set It
Maximum threshold for total host memory usage (KB)	Specify the maximum amount of memory usage that can occur on the host computer before an event is raised. The default is 20000 kilobytes.

75.35 VirtualMachineInventory

Use this Knowledge Script to monitor hosts and virtual machines that are added, removed, renamed, moved, migrated, or edited in vCenter. This script raises an event when any of the listed actions occurs. In addition, this script can perform a rediscovery when these events occur, which allows the AppManager console to display the most current inventory of hosts and virtual machines in vCenter.

NetIQ Corporation recommends you use the Inventory Knowledge Script instead of this script for inventory monitoring.

NOTE: In rare situations, queries to the ESX or ESXi host might fail with timeouts because the ESX or ESXi host stops responding. You can work around this issue by restarting the management service on the ESX or ESXi host.

75.35.1 Resource Object

vCenter server

75.35.2 Default Schedule

By default, this script runs every **hour**.

75.35.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Event Notification	**Important** If you are using this module with AppManager 8.0, the following *Raise event...* parameters should be unselected. Use the Inventory Knowledge Script if you want to raise events related to inventory changes with AppManager 8.0.
Raise event when virtual machines added?	Select **Yes** to raise an event when a virtual machine is added to vCenter. The default is Yes.
Event severity when virtual machines added	Set the event severity level, from 1 to 40, to indicate the importance of an event in which a virtual machine is added to vCenter. The default is 15.
Raise event when virtual machines removed?	Select **Yes** to raise an event when a virtual machine is removed from vCenter. The default is Yes.
Event severity when virtual machines removed	Set the event severity level, from 1 to 40, to indicate the importance of an event in which a virtual machine is removed from vCenter. The default is 15.
Raise event when virtual machines renamed?	Select **Yes** to raise an event when a virtual machine is renamed. The default is Yes.
Event severity when virtual machines renamed	Set the event severity level, from 1 to 40, to indicate the importance of an event in which a virtual machine is renamed. The default is 15.
Raise event when virtual machines moved?	Select **Yes** to raise an event when a virtual machine is moved within vCenter. The default is unselected.

Parameter	How to Set It
Event severity when virtual machines moved	Set the event severity level, from 1 to 40, to indicate the importance of an event in which a virtual machines is moved within vCenter. The default is 15.
Raise event when virtual machines migrated?	Select **Yes** to raise an event when a virtual machine is migrated within vCenter. The default is Yes.
Event severity when virtual machines migrated	Set the event severity level, from 1 to 40, to indicate the importance of an event in which virtual machines are migrated within vCenter. The default is 15.
Raise event when rediscovery failed?	Select **Yes** to raise an event when rediscovery fails. The default is unselected.
Event severity when rediscovery fails	Set the event severity level, from 1 to 40, to indicate the importance of an event in which rediscovery fails. The default is 5.
Event severity when AppManager failed to get metrics	Set the event severity level, from 1 to 40, to indicate the importance of an event in which AppManager failed to retrieve metrics from vCenter. The default is 15.
Event severity when AppManager failed to log in	Set the event severity level, from 1 to 40, to indicate the importance of an event in which AppManager failed to log in to vCenter. The default is 5.
Event severity when VirtualMachineInventory job fails unexpectedly	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the VirtualMachineInventory job fails unexpectedly. The default is 5.
Event severity when writing XML to file successful	Set the event severity level, from 1 to 40, to indicate the importance of an event in which writing the XML code to a file succeeds. The default is 25.
Data Collection	
Collect data when virtual machines are added?	Select **Yes** to collect data about virtual machines that are added to vCenter. The default is unselected.
Collect data when virtual machines are removed?	Select **Yes** to collect data about virtual machines that are removed from vCenter. The default is unselected.
Collect data when virtual machines are renamed?	Select **Yes** to collect data about virtual machines that are renamed within vCenter. The default is unselected.
Collect data when virtual machines are moved?	Select **Yes** to collect data about virtual machines that are moved within vCenter. The default is unselected.
Collect data when virtual machines are migrated?	Select **Yes** to collect data about virtual machines that are migrated in vCenter. The default is unselected.
Rediscovery Options	**Important** If you are using this module with AppManager 8.0, select Yes for the following *Rediscover* parameters. Do not use the discovery parameters in the Inventory Knowledge Script.
Rediscover if virtual machines are added?	Select **Yes** to perform rediscovery when a virtual machine is added to vCenter. The default is unselected.
Rediscover if virtual machines are removed?	Select **Yes** to perform rediscovery when a virtual machine is removed from vCenter. The default is unselected.
Rediscover if virtual machines are renamed?	Select **Yes** to perform rediscovery when a virtual machine is renamed within vCenter. The default is unselected.
Rediscover if virtual machines are moved?	Select **Yes** to perform rediscovery when a virtual machine is moved within vCenter. The default is unselected.

Parameter	How to Set It
Rediscover if virtual machines are migrated?	Select **Yes** to perform rediscovery when a virtual machine is migrated in vCenter. The default is unselected.

75.36 VmConnected

Use this Knowledge Script to monitor changes in the connection status of virtual machines to vCenter. This script raises an event if a virtual machine is disconnected or reconnected.

NOTE:

- If the parent host of the monitored virtual machine is in maintenance mode, this Knowledge Script will not generate events.
- Using this script and other VirtualCenter_Vm* scripts to monitor a large number of virtual machines at the same time might cause the jobs to fail. If the jobs fail on a regular basis, consider running the VirtualCenter_Vm* scripts on fewer virtual machines.

75.36.1 Resource Object

vSphere virtual machine

75.36.2 Default Schedule

By default, this script runs every day at 15 minute intervals starting at 12:01 AM and ending at 11:59 PM. If you start the job after the scheduled starting time, the script runs at the time of the next scheduled interval. For example, if you start the job at 12:10 AM, it runs for the first time at 12:16 AM.

NOTE: If you are running this script as part of the Recommended Knowledge Script Groups, do not change the schedule. The schedules for the recommended scripts are staggered to lessen the impact on CPU utilization when you run the KSG.

75.36.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Job Failure Notification	
Raise event when status information is not available?	Select **Yes** to raise an event when information about the virtual machine's connection status is not available. The default is unselected.
Event severity when status information is not available	Set the event severity level, from 1 to 40, to indicate the importance of an event in which information about the virtual machine's connection status is not available. The default is 15.
Event severity when AppManager failed to get metrics	Set the event severity level, from 1 to 40, to indicate the importance of an event in which AppManager failed to retrieve metrics from vCenter. The default is 15.
Event severity when AppManager failed to log in	Set the event severity level, from 1 to 40, to indicate the importance of an event in which AppManager failed to log in to vCenter. The default is 5.

Parameter	How to Set It
Event severity when VmConnected job fails unexpectedly	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the VmConnected job fails unexpectedly. The default is 5.
Additional Settings	
Event Details	
Event detail format	Select either **HTML Table** or **Plain Text** as the format for event detail. The default is HTML Table.
Monitor Connection Status	
Event Notification	
Raise event when a virtual machine is disconnected	Select **Yes** to raise an event when a connected virtual machine is disconnected from vCenter. The default is Yes.
Event severity when virtual machine is disconnected	Set the event severity level, from 1 to 40, to indicate the importance of an event in which a virtual machine is disconnected from vCenter. The default is 15.
Raise event when a virtual machine is reconnected	Select **Yes** to raise an event when a disconnected virtual machine is reconnected to vCenter. The default is Yes.
Event severity when virtual machine is reconnected	Set the event severity level, from 1 to 40, to indicate the importance of an event in which a virtual machine is reconnected to vCenter. The default is 15.

75.37 VmCPUUsage

Use this Knowledge Script to monitor the following CPU metrics for a virtual machine:

- CPU ready - Percentage of time that the virtual machine was ready, but could not get scheduled to run on the physical CPU. CPU ready time is dependent on the number of virtual machines on the host and their CPU loads.
- CPU system - Amount of time spent on system processes on each virtual CPU in the virtual machine.
- CPU usage - Amount of actively used virtual CPU, as a percentage of total available CPU. This is the host's view of the CPU usage, not the guest operating system's view. It is the average CPU utilization over all available virtual CPUs in the virtual machine.
- CPU usage in MHz - Total amount of CPU used, in MHz, during the interval. This is the same value as CPU usage represented in MHz instead of a percentage.
- CPU used - Total CPU usage. CPU used as a percentage and CPU usage as a percentage are the same value.
- CPU wait - Amount of CPU time spent in wait state.

This script raises an event if a monitored value exceeds the threshold you set.

NOTE:

- If the parent host of the monitored virtual machine is in maintenance mode, this Knowledge Script will not generate events.
- Using this script and other VirtualCenter_Vm* scripts to monitor a large number of virtual machines at the same time might cause the jobs to fail. If the jobs fail on a regular basis, consider running the VirtualCenter_Vm* scripts on fewer virtual machines.
- CPU wait is a combined metric that includes CPU idle, CPU wait, and CPU halted. CPU wait is a defect in VMware. NetIQ Corporation is currently researching a solution with VMware (SR #1123183421). AppManager matches the value provided by VMware. For more information about this issue, see the VI SDK Release Notes athttp://www.vmware.com/support/developer/vc-sdk/visdk-2.5.0-200711-releasenotes.html.
- In vCenter version 2.0.2 environments, event and datastream values for the CPU Wait metric correspond to the value of the CPU Idle metric.

75.37.1 Resource Object

vSphere virtual machine

75.37.2 Default Schedule

By default, this script runs every day at 15 minute intervals starting at 12:05 AM and ending at 11:59 PM. If you start the job after the scheduled starting time, the script runs at the time of the next scheduled interval. For example, if you start the job at 12:10 AM, it runs for the first time at 12:20 AM.

NOTE: If you are running this script as part of the Recommended Knowledge Script Groups, do not change the schedule. The schedules for the recommended scripts are staggered to lessen the impact on CPU utilization when you run the KSG.

75.37.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Job Failure Notification	
Raise event when CPU metrics are not available?	Select **Yes** to raise an event if CPU metrics are not available. The default is unselected.
Event severity when CPU metrics are not available	Set the event severity level, from 1 to 40, to indicate the importance of an event in which CPU metrics are not available. The default is 15.
Event severity when AppManger failed to get metrics	Set the event severity level, from 1 to 40, to indicate the importance of an event in which AppManager failed to retrieve metrics from vCenter. The default is 15.
Event severity when AppManager failed to log in	Set the severity level, from 1 to 40, to indicate the importance of an event in which AppManager failed to log in to vCenter. The default is 5.
Event severity when VmCPUUsage job fails unexpectedly	Set the severity level, from 1 to 40, to indicate the importance of an event in which the VmCPUUsage job fails unexpectedly. The default is 5.
Additional Settings	
Event Details	
Event detail format	Select either **HTML Table** or **Plain Text** as the format for event detail. The default is HTML Table.
Monitoring CPU Ready	
Event Notification	
Raise event when average CPU ready exceeds the threshold?	Select **Yes** to raise an event when average CPU ready exceeds the threshold you set. The default is Yes.
Threshold – Maximum average CPU ready	Specify the maximum average CPU ready that can occur before an event is raised. The default is 10 percent.
Event severity when average CPU ready exceeds the threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event when average CPU ready exceeds the threshold. The default is 15.
Data Collection	
Collect data for average CPU ready?	Select **Yes** to collect data about average CPU ready for charts and reports. The default is unselected.
Collect data for individual CPU ready?	Select **Yes** to collect data about individual CPU ready for charts and reports. The default is unselected.
Monitoring CPU System	
Event Notification	
Raise event when average CPU system exceeds the threshold?	Select **Yes** to raise an event when average CPU system exceeds the threshold you set. The default is unselected.
Threshold – Maximum average CPU system	Specify the maximum average CPU system that can occur before an event is raised. The default is 20 percent.
Event severity when average CPU system exceeds the threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event when average CPU system exceeds the threshold. The default is 15.

Parameter	How to Set It
Raise event when individual CPU system exceeds the threshold?	Select **Yes** to raise an event when individual CPU system exceeds the threshold you set. The default is unselected.
Threshold – Maximum individual CPU system	Specify the maximum individual CPU system that can occur before an event is raised. The default is 20 percent.
Event severity when individual CPU system exceeds the threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event when individual CPU system exceeds the threshold. The default is 15.
Data Collection	
Collect data for average CPU system?	Select **Yes** to collect data about average CPU system for charts and reports. The default is unselected.
Collect data for individual CPU system?	Select **Yes** to collect data about individual CPU system for charts and reports. The default is unselected.
Monitoring CPU Usage	
Event Notification	
Raise event when average CPU usage exceeds the threshold?	Select **Yes** to raise an event when average CPU usage exceeds the threshold you set. The default is Yes.
Threshold – Maximum average CPU usage	Specify the maximum average CPU usage that can occur before an event is raised. The default is 80 percent.
Event severity when average CPU usage exceeds the threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event when average CPU usage exceeds the threshold. The default is 15.
Data Collection	
Collect data for average CPU usage?	Select **Yes** to collect data about average CPU usage for charts and reports. The default is unselected.
Collect data for individual CPU usage?	Select **Yes** to collect data about individual CPU usage for charts and reports. The default is unselected.
Monitoring CPU Usage in MHz	
Event Notification	
Raise event when average CPU usage in MHz exceeds the threshold?	Select **Yes** to raise an event when average CPU usage in MHz exceeds the threshold you set. The default is unselected.
Threshold – Maximum average CPU usage in MHz	Specify the maximum average CPU usage in MHz that can occur before an event is raised. The default is 2000 MHz.
Event severity when average CPU usage in MHz exceeds the threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event when average CPU usage in MHz exceeds the threshold. The default is 15.
Raise event when individual CPU usage in MHz exceeds the threshold?	Select **Yes** to raise an event when individual CPU usage in MHz exceeds the threshold you set. The default is unselected.
Threshold – Maximum individual CPU usage in MHz	Specify the maximum individual CPU usage in MHz that can occur before an event is raised. The default is 2000 MHz.
Event severity when individual CPU usage in MHz exceeds the threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event when individual CPU usage in MHz exceeds the threshold. The default is 15.
Data Collection	

Parameter	How to Set It
Collect data for average CPU usage in MHz?	Select **Yes** to collect data about average CPU usage in MHz for charts and reports. The default is unselected.
Collect data for individual CPU usage in MHz?	Select **Yes** to collect data about individual CPU usage in MHz for charts and reports. The default is unselected.
Monitoring CPU Used	
Event Notification	
Raise event when average CPU used exceeds the threshold?	Select **Yes** to raise an event when average CPU used exceeds the threshold you set. The default is Yes.
Threshold – Maximum average CPU used	Specify the maximum average CPU used that can occur before an event is raised. The default is 80 percent.
Event severity when average CPU used exceeds the threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event when average CPU used exceeds the threshold. The default is 15.
Data Collection	
Collect data for average CPU used?	Select **Yes** to collect data about average CPU used for charts and reports. The default is unselected.
Collect data for individual CPU used?	Select **Yes** to collect data about individual CPU used for charts and reports. The default is unselected.
Monitoring CPU Wait	
Event Notification	
Raise event when average CPU wait exceeds the threshold?	Select **Yes** to raise an event when average CPU wait exceeds the threshold you set. The default is unselected.
Threshold – Maximum average CPU wait	Specify the maximum average CPU wait that can occur before an event is raised. The default is 10 percent.
Event severity when average CPU wait exceeds the threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event when average CPU wait exceeds the threshold. The default is 15.
Data Collection	
Collect data for average CPU wait?	Select **Yes** to collect data about average CPU wait for charts and reports. The default is unselected.
Collect data for individual CPU wait?	Select **Yes** to collect data about individual CPU wait for charts and reports. The default is unselected.

75.38 VmDiskIO

Use this Knowledge Script to monitor disk reads/writes for a virtual machine. This script raises an event if the rate of reads/writes exceeds the threshold you set. This script monitors and collects data for the following performance metrics:

- Disk read rate - Rate at which data is read from each virtual disk on the virtual machine
- Disk write rate - Rate at which data is written to each virtual disk on the virtual machine
- Total disk I/O for the virtual disk

NOTE:

- If the parent host of the monitored virtual machine is in maintenance mode, this Knowledge Script will not generate events.
- Using this script and other VirtualCenter_Vm* scripts to monitor a large number of virtual machines at the same time might cause the jobs to fail. If the jobs fail on a regular basis, consider running the VirtualCenter_Vm* scripts on fewer virtual machines.

75.38.1 Resource Object

vSphere virtual machine

75.38.2 Default Schedule

By default, this script runs every day at 15 minute intervals starting at 12:07 AM and ending at 11:59 PM. If you start the job after the scheduled starting time, the script runs at the time of the next scheduled interval. For example, if you start the job at 12:10 AM, it runs for the first time at 12:22 AM.

NOTE: If you are running this script as part of the Recommended Knowledge Script Groups, do not change the schedule. The schedules for the recommended scripts are staggered to lessen the impact on CPU utilization when you run the KSG.

75.38.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Event Notification	
Raise event when total disk IO exceeds the threshold?	Select **Yes** to raise an event when total disk IO exceeds the threshold you set. The default is unselected.
Event severity when total disk IO exceeds the threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which total disk IO exceeds the threshold you set. The default is 15
Raise event when average disk reads exceed the threshold?	Select **Yes** to raise an event when average disk reads exceed the threshold you set. The default is Yes.

Parameter	How to Set It
Event severity when average disk reads exceed the threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which average disk reads exceed the threshold. The default is 15.
Raise event when disk writes exceed the threshold?	Select **Yes** to raise an event if the rate of disk writes exceeds the threshold you set. The default is Yes.
Event severity when disk writes exceed the threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which disk writes exceeds the threshold. The default is 15.
Raise event when disk I/O metrics are not available?	Select **Yes** to raise an event if disk I/O metrics are not available. The default is unselected.
Event severity when disk I/O metrics are not available	Set the event severity level, from 1 to 40, to indicate the importance of an event in which disk I/O metrics are not available. The default is 15.
Event severity when AppManager failed to get metrics	Set the event severity level, from 1 to 40, to indicate the importance of an event in which AppManager failed to retrieve metrics from vCenter. The default is 15.
Event severity when AppManager failed to log in	Set the event severity level, from 1 to 40, to indicate the importance of an event in which AppManager failed to log in to vCenter. The default is 5.
Event severity when VmDiskIO job fails unexpectedly.	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the VmDiskIO job fails unexpectedly. The default is 5.
Data Collection	
Collect data for total disk IO?	Select **Yes** to collect data about total disk IO for charts and reports. The default is unselected.
Collect data for average disk reads?	Select **Yes** to collect data about average disk reads for charts and reports. The default is unselected.
Collect data for average disk writes?	Select **Yes** to collect data about average disk writes for charts and reports. The default is unselected.
Monitoring	
Maximum threshold for disk IO	Specify the maximum rate at which disk IO can occur before an event is raised. The default is 20 megabytes per second.
Maximum threshold for average disk reads	Specify the maximum rate at which average disk reads can occur before an event is raised. The default is 1 megabyte per second.
Maximum threshold for average disk writes	Specify the maximum rate at which average disk writes can occur before an event is raised. The default is 1 megabyte per second.

75.39 VmDiskUsage

Use this Knowledge Script to monitor logical disk usage for a virtual machine. This script raises an event when the disk usage exceeds the threshold you set.

This Knowledge Script cannot monitor the logical disk usage for a virtual machine when the virtual machine's disk is a mounted drive.

NOTE:

- If the parent host of the monitored virtual machine is in maintenance mode, this Knowledge Script will not generate events.
- Using this script and other VirtualCenter_Vm* scripts to monitor a large number of virtual machines at the same time might cause the jobs to fail. If the jobs fail on a regular basis, consider running the VirtualCenter_Vm* scripts on fewer virtual machines.

75.39.1 Resource Object

vSphere virtual machine

75.39.2 Default Schedule

By default, this script runs every **15 minutes**.

75.39.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Job Failure Notification	
Raise event when disk metrics are not available?	Select **Yes** to raise an event when disk metrics are not available. The default is unselected.
Event severity when disk metrics are not available	Set the event severity level, from 1 to 40, to indicate the importance of an event in which disk metrics are not available. The default is 15.
Event severity when AppManager failed to get metrics	Set the event severity level, from 1 to 40, to indicate the importance of an event in which AppManager failed to get metrics. The default is 15.
Event severity when AppManager failed to log in	Set the event severity level, from 1 to 40, to indicate the importance of an event in which AppManager failed to log in. The default is 5.
Event severity when VMDiskUsage job fails unexpectedly	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the VMDiskUsage job fails unexpectedly. The default is 5.
Additional Settings	

Parameter	How to Set It
Event Details	
Event detail format	Select either **HTML Table** or **Plain Text** as the format for event detail. The default is HTML Table.
Monitor Logical Disk Usage	
Event Notification	
Raise event if logical disk free space falls below the threshold	Select **Yes** to raise an event when logical disk free space falls below the threshold you set. The default is Yes.
Unit type	Select whether to measure the amount of logical disk free space in **Percent**, **MBytes**, or **GBytes**. The default is MBytes.
Threshold – Minimum logical disk free space available	Specify the minimum amount of logical disk free space that can be available before an event is raised. The default is 500 MBytes.
Event severity when logical disk free space falls below the threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which logical disk available free space falls below the threshold. The default is 15.
Raise event if logical disk space usage exceeds the threshold	Select **Yes** to raise an event when logical disk space usage exceeds the threshold you set. The default is Yes.
Unit type	Select whether to measure the amount of disk space usage in **Percent**, **MBytes**, or **GBytes**. The default is Percent.
Threshold – Maximum logical disk space usage	Specify the amount of logical disk space usage that can occur before an event is raised. The default is 80 percent.
Event severity when logical disk space usage exceeds the threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which logical disk space usage exceeds the threshold. The default is 15.
Data Collection	
Collect data for logical disk free space?	Select **Yes** to collect data about logical disk free space for charts and reports. The default is unselected.
Collect data for logical disk space usage?	Select **Yes** to collect data about logical disk space usage for charts and reports. The default is unselected.

75.40 VmMemoryUsage

Use this Knowledge Script to monitor memory usage for a virtual machine. This script raises an event if a monitored metric exceeds the threshold you set. This script monitors and collects data for the following performance metrics:

- Memory active - Amount of guest physical memory in use by the virtual machine. This is an estimate provided by the VMkernel and represents the actual amount of memory the virtual machine needs.
- Memory balloon - Amount of guest physical memory that is currently reclaimed from the virtual machine through ballooning. This is the amount of guest physical memory that has been allocated and pinned by the balloon driver.
- Memory consumed - Amount of guest physical memory consumed by the virtual machine for guest memory. Consumed memory does not include overhead memory. It includes shared memory and memory that might be reserved, but not actually used.
- Memory granted - Guest "physical" memory that is mapped to machine memory.
- Memory overhead - Amount of overhead memory (in kilobytes) required for virtualization of the virtual machine. Excess memory overhead values can indicate virtualization problems.
- Memory shared - Amount of guest "physical" memory shared with other virtual machines (through the VMkernel's transparent page-sharing mechanism, a RAM de-duplication technique).
- Memory state - Amount of free machine memory on the host. The VMkernel has four free-memory thresholds that affect memory reclamation:
  - 0 (high) Free memory $\geq$ 6% of machine memory minus Service Console memory.
  - 1 (soft) 4%
  - 2 (hard) 2%
  - 3 (low) 1%
  - 0 (high) and 1 (soft): Swapping is favored over ballooning.
  - 2 (hard) and 3 (low): Ballooning is favored over swapping.
- Memory swap in - Total amount of data that has been read into machine memory from the swap file since the virtual machine was powered on.
- Memory swap in rate - Rate at which memory is swapped from disk into active memory.
- Memory swap out - Total amount of data that the VMkernel has written to the virtual machine's swap file from machine memory. This statistic refers to VMkernel swapping and not to guest OS swapping.
- Memory swap out rate - Rate at which memory is being swapped from active memory to disk.
- Memory usage - Percentage of total configured or available memory usage.
- Memory zero - Memory (as a percentage) that is zeroed out. This value can indicate that there are virtual machines with more memory allocated to them than they need. By reducing the allocated memory you can increase the total number of running virtual machines, achieving a greater virtual to physical running ratio.

NOTE:

- If the parent host of the monitored virtual machine is in maintenance mode, this Knowledge Script will not generate events.
- Using this script and other VirtualCenter_Vm* scripts to monitor a large number of virtual machines at the same time might cause the jobs to fail. If the jobs fail on a regular basis, consider running the VirtualCenter_Vm* scripts on fewer virtual machines.

75.40.1 Resource Object

vSphere virtual machine

75.40.2 Default Schedule

By default, this script runs every day at 15 minute intervals starting at 12:03 AM and ending at 11:59 PM. If you start the job after the scheduled starting time, the script runs at the time of the next scheduled interval. For example, if you start the job at 12:10 AM, it runs for the first time at 12:18 AM.

NOTE: If you are running this script as part of the Recommended Knowledge Script Groups, do not change the schedule. The schedules for the recommended scripts are staggered to lessen the impact on CPU utilization when you run the KSG.

75.40.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Job Failure Notification	
Raise event when memory metrics are not available?	Select **Yes** to raise an event if memory metrics are not available. The default is unselected.
Event severity when memory metrics are not available	Set the event severity level, from 1 to 40, to indicate the importance of an event in which memory metrics are not available. The default is 15.
Event severity when AppManager failed to get metrics	Set the event severity level, from 1 to 40, to indicate the importance of an event in which AppManager failed to retrieve metrics from vCenter. The default is 15.
Event severity when AppManager failed to log in	Set the event severity level, from 1 to 40, to indicate the importance of an event in which AppManager failed to log in to vCenter. The default is 5.
Event severity when VmMemoryUsage job fails unexpectedly	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the VmMemoryUsage job fails unexpectedly. The default is 5.
Additional Settings	
Event Details	
Event detail format	Select either **HTML Table** or **Plain Text** as the format for event detail. The default is HTML Table.
Monitoring Memory Active	
Event Notification	
Raise event when memory active exceeds the threshold?	Select **Yes** to raise an event when the memory active exceeds the threshold you set. The default is unselected.
Threshold – Maximum for memory active	Specify the maximum percentage for memory active before an event is raised. The default is 20 percent.

Parameter	How to Set It
Event severity when memory active exceeds the threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event when the active memory exceeds the threshold. The default is 15.
Data Collection	
Collect data for memory active?	Select **Yes** to collect data about memory active for charts and reports. The default is unselected.
Monitor Memory Balloon	
Event Notification	
Raise event when memory balloon exceeds the threshold?	Select **Yes** to raise an event if the percentage of memory balloon exceeds the threshold you set. The default is Yes.
Threshold – Maximum memory balloon	Specify the maximum percentage for memory balloon before an event is raised. The default is 2 percent.
Event severity when memory balloon exceeds the threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the percentage of memory balloon exceeds the threshold. The default is 15.
Data Collection	
Collect data for memory balloon?	Select **Yes** to collect data about memory balloon for charts and reports. The default is unselected.
Monitor Memory Consumed	
Event Notification	
Raise event when memory consumed exceeds the threshold?	Select **Yes** to raise an event if the percentage of memory consumed exceeds the threshold you set. The default is Yes.
Threshold – Maximum memory consumed	Specify the maximum percentage of memory consumed before an event is raised. The default is 80 percent.
Event severity when memory consumed exceeds the threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the percentage of memory consumed exceeds the threshold. The default is 15.
Data Collection	
Collect data for memory consumed?	Select **Yes** to collect data about memory consumed for charts and reports. The default is unselected.
Monitor Memory Granted	
Event Notification	
Raise event when memory granted exceeds the threshold?	Select **Yes** to raise an event when the amount of memory granted exceeds the threshold you set. The default is unselected.
Threshold – Maximum memory granted	Specify the maximum amount of memory granted before an event is raised. The default is 1024 megabytes.
Event severity when memory granted exceeds the threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the amount of memory granted exceeds the threshold. The default is 15.
Data Collection	
Collect data for memory granted?	Select **Yes** to collect data about memory granted for charts and reports. The default is unselected.
Monitor Memory Overhead	

Parameter	How to Set It
Event Notification	
Raise event when memory overhead exceeds the threshold?	Select **Yes** to raise an event when the amount of memory overhead exceeds the threshold you set. The default is unselected.
Threshold –Maximum memory overhead	Specify the maximum amount of memory overhead that can occur before an event is raised. The default is 100 megabytes.
Event severity when memory overhead exceeds the threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the amount of memory shared exceeds the threshold. The default is 15.
Data Collection	
Collect data for memory overhead?	Select **Yes** to collect data about memory overhead for charts and reports. The default is unselected.
Monitor Memory Shared	
Event Notification	
Raise event when memory shared falls below the threshold?	Select **Yes** to raise an event when the amount of memory shared falls below the threshold you set. The default is unselected.
Threshold –Maximum memory shared	Specify the maximum amount of memory shared that can occur before an event is raised. The default is 50 megabytes.
Event severity when memory shared exceeds the threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the amount of memory shared exceeds the threshold. The default is 15.
Data Collection	
Collect data for memory shared?	Select **Yes** to collect data about memory shared for charts and reports. The default is unselected.
Monitor Memory State	
Event Notification	
Raise event when memory state is hard?	Select **Yes** to raise an event when the memory state is hard. The default is unselected.
Event severity when memory state is hard	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the memory state is hard. The default is 10.
Raise event when memory state is high?	Select **Yes** to raise an event when the memory state is high. The default is unselected.
Event severity when memory state is high	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the memory state is high. The default is 25.
Raise event when memory state is low?	Select **Yes** to raise an event when the memory state is low. The default is unselected.
Event severity when memory state is low	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the memory state is low. The default is 5.
Raise event when memory state is soft?	Select **Yes** to raise an event when memory state is soft. The default is unselected.
Event severity when memory state is soft	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the memory state is soft. The default is 15.
Data Collection	
Collect data for memory state?	Select **Yes** to collect data about memory state for charts and reports. The default is unselected.

Parameter	How to Set It
Monitor Memory Swap In	
Data Collection	
Collect data for memory swap in?	Select **Yes** to collect data about memory swap in for charts and reports. The default is unselected.
Monitor Memory Swap In Rate	
Event Notification	
Raise event when memory swap in rate exceeds the threshold?	Select **Yes** to raise an event when the memory swap in rate exceeds the threshold you set. The default is Yes.
Threshold – Maximum memory swap in rate	Specify the maximum memory swap in rate that can occur before an event is raised. The default is 1 megabyte per second.
Event severity when memory swap in rate exceeds the threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the memory swap in rate exceeds the threshold. The default is 15.
Data Collection	
Collect data for memory swap in rate?	Select **Yes** to collect data about memory swap in rate for charts and reports. The default is unselected.
Monitor Memory Swap Out	
Data Collection	
Collect data for memory swap out?	Select **Yes** to collect data about memory swap out for charts and reports. The default is unselected.
Monitor Memory Swap Out Rate	
Event Notification	
Raise event when memory swap out rate exceeds the threshold?	Select **Yes** to raise an event when the memory swap out rate exceeds the threshold you set. The default is Yes.
Threshold – Maximum memory swap out rate	Specify the maximum memory swap out rate that can occur before an event is raised. The default is 1 megabyte per second.
Event severity when memory swap out rate exceeds the threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the memory swap out rate exceeds the threshold. The default is 15.
Data Collection	
Collect data for memory swap out rate?	Select **Yes** to collect data about memory swap out rate for charts and reports. The default is unselected.
Monitor Memory Usage	
Event Notification	
Raise event when memory usage exceeds the threshold?	Select **Yes** to raise an event when memory usage exceeds the threshold you set. The default is Yes.
Threshold – Maximum memory usage	Specify the maximum memory usage that can occur before an event is raised. The default is 80 percent.
Event severity when memory usage exceeds the threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which memory usage exceeds the threshold. The default is 15.
Data Collection	

Parameter	How to Set It
Collect data for memory usage?	Select **Yes** to collect data about memory usage for charts and reports. The default is unselected.
Monitor Memory Zero	
Event Notification	
Raise event when memory zero exceeds the threshold?	Select **Yes** to raise an event when memory zero exceeds the threshold you set. The default is unselected.
Threshold – Maximum memory zero	Specify the maximum memory zero that can occur before an event is raised. The default is 20 percent.
Event severity when memory zero exceeds the threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which memory zero exceeds the threshold. The default is 15.
Data Collection	
Collect data for memory zero?	Select **Yes** to collect data about memory zero for charts and reports. The default is unselected.

75.41 VmNetworkIO

Use this Knowledge Script to monitor network data received/transmitted for a virtual machine. This script raises an event if the rate of network received/transmitted exceeds the threshold you set. This script monitors and collects data for the following performance metrics:

- Network received - The rate at which data is received across the virtual machine's vNIC (virtual network interface controller).
- Network transmitted (Network I/O) - The rate at which data is transmitted across the virtual machine's vNIC (virtual network interface controller).

NOTE:

- If the parent host of the monitored virtual machine is in maintenance mode, this Knowledge Script will not generate events.
- Using this script and other VirtualCenter_Vm* scripts to monitor a large number of virtual machines at the same time might cause the jobs to fail. If the jobs fail on a regular basis, consider running the VirtualCenter_Vm* scripts on fewer virtual machines.

75.41.1 Resource Object

vSphere virtual machine

75.41.2 Default Schedule

By default, this script runs every day at 15 minute intervals starting at 12:09 AM and ending at 11:59 PM. If you start the job after the scheduled starting time, the script runs at the time of the next scheduled interval. For example, if you start the job at 12:10 AM, it runs for the first time at 12:24 AM.

NOTE: If you are running this script as part of the Recommended Knowledge Script Groups, do not change the schedule. The schedules for the recommended scripts are staggered to lessen the impact on CPU utilization when you run the KSG.

75.41.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Event Notification	
Raise event when network received exceeds the threshold?	Select **Yes** to raise an event if the rate of network data received exceeds the threshold you set. The default is Yes.
Event severity when network data received exceeds the threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the rate of network data received exceeds the threshold. The default is 15.
Raise event when individual network data received exceeds the threshold?	Select **Yes** to raise an event if the rate of individual network data received exceeds the threshold you set. The default is unselected.

Parameter	How to Set It
Event severity when individual network data received exceeds the threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the rate of individual network data received exceeds the threshold. The default is 15.
Raise event when network data transmitted exceeds the threshold?	Select **Yes** to raise an event if the rate of network data transmitted exceeds the threshold you set. The default is Yes.
Event severity when network data transmitted exceed the threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the rate of network data transmitted exceeds the threshold. The default is 15.
Raise event when individual network data transmitted exceeds the threshold?	Select **Yes** to raise an event if the rate of individual network data transmitted exceeds the threshold you set. The default is unselected.
Event severity when individual network data transmitted exceeds the threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the rate of individual network data received exceed the threshold. The default is 15.
Raise event when network I/O metrics are not available?	Select **Yes** to raise an event if network I/O metrics are not available. The default is unselected.
Event severity when network I/O metrics are not available	Set the event severity level, from 1 to 40, to indicate the importance of an event in which network I/O metrics are not available. The default is 15.
Event severity when AppManager failed to get metrics	Set the event severity level, from 1 to 40, to indicate the importance of an event in which AppManager failed to retrieve metrics from vCenter. The default is 15.
Event severity when AppManager failed to log in	Set the event severity level, from 1 to 40, to indicate the importance of an event in which AppManager failed to log in to vCenter. The default is 5.
Event severity when VmNetworkI/O job fails unexpectedly	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the VmNetworkIO job fails unexpectedly. The default is 5.
Data Collection	
Collect data for network data received?	Select **Yes** to collect data about the rate of network data received for charts and reports. The default is unselected.
Collect data for individual network data received?	Select **Yes** to collect data about the rate of individual network data received for charts and reports. The default is unselected.
Collect data for network writes?	Select **Yes** to collect data about the rate of network writes for charts and reports. The default is unselected.
Collect data for network individual writes?	Select **Yes** to collect data about the rate of individual network writes for charts and reports. The default is unselected.
Monitoring	
Maximum threshold for network data received	Specify the maximum rate at which network data received can occur before an event is raised. The default is 1 Mbit per second.
Maximum threshold for individual network data received	Specify the maximum rate at which individual network data received can occur before an event is raised. The default is 1 Mbit per second.
Maximum threshold for network writes	Specify the maximum rate at which network writes can occur before an event is raised. The default is 1 Mbit per second.
Maximum threshold for individual network writes	Specify the maximum rate at which individual network writes can occur before an event is raised. The default is 1 Mbit per second.

75.42 VmOperations

Use this Knowledge Script to monitor the number of virtual machine operations that are occurring across clusters and datacenters. You can also use this script to raise events when the number of Storage vMotions or vMotions exceed a specified threshold. This script generates data streams for Storage vMotion operations and vMotion operations.

NOTE: The VirtualCenter_VmOperations Knowledge Script is supported on vCenter 4.0 or later.

75.42.1 Resource Object

vSphere datacenters and clusters

75.42.2 Default Schedule

By default, this script runs every **5 minutes.**

75.42.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Job Failure Notification	
Raise event when virtual machine operation metrics are not available?	Select **Yes** to raise an event if virtual machine operation metrics are not available.The default is unselected.
Event severity when virtual machine operation metrics are not available	Set the event severity level, from 1 to 40, to indicate the importance of an event in which virtual machine operation metrics are not available. The default is 15.
Event severity when AppManager failed to get metrics	Set the event severity level, from 1 to 40, to indicate the importance of an event in which AppManager failed to retrieve virtual machine operation status from vCenter. The default is 15.
Event severity when AppManager failed to log in	Set the event severity level, from 1 to 40, to indicate the importance of an event in which AppManager failed to log in to vCenter. The default is 5.
Event severity when VmOperations job fails unexpectedly	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the VmOperations job fails unexpectedly. The default is 5.
Additional Settings	
Event Details	
Event detail format	Select either **HTML Table** or **Plain Text** as the format for event detail. The default is HTML Table.
Monitor Virtual Machine Operations	

Parameter	How to Set It
Event Notification	
Raise event if Storage vMotions exceed the threshold?	Select Yes to raise an event if the number of Storage vMotions exceeds the threshold you set. The default is unselected.
Threshold – Maximum Storage vMotions	Specify the maximum number of Storage vMotions that can occur before raising an event. The default is 10.
Event severity when Storage vMotions exceed the threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of Storage vMotions exceeds the threshold. The default is 15.
Raise event if vMotions exceed the threshold?	Select Yes to raise an event if the number of vMotions exceeds the threshold you set. The default is unselected.
Threshold – Maximum vMotions	Specify the maximum number of vMotions that can occur before raising an event. The default is 10.
Event severity when vMotions exceed the threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of vMotions exceeds the threshold. The default is 15.
Data Collection	
Collect data for Storage vMotions?	Select **Yes** to collect data about Storage vMotions for charts and reports. The default is Yes.
Collect data for vMotions?	Select **Yes** to collect data about vMotions for charts and reports. The default is Yes.

75.43 VmPowerStatus

Use this Knowledge Script to monitor changes in the power status of virtual machines. This script raises an event if a virtual machine is powered on, powered off, or suspended. Based on these events, you can choose to restart, stop, or resume the monitored virtual machines.

NOTE:

- If the parent host of the monitored virtual machine is in maintenance mode, this Knowledge Script will not generate events.
- Using this script and other VirtualCenter_Vm* scripts to monitor a large number of virtual machines at the same time might cause the jobs to fail. If the jobs fail on a regular basis, consider running the VirtualCenter_Vm* scripts on fewer virtual machines.

75.43.1 Prerequisite

Enable Power On, Power Off, Suspend, and Restart permissions to run this Knowledge Script. For more information, see .

75.43.2 Resource Object

vSphere virtual machine

75.43.3 Default Schedule

By default, this script runs every **15 minutes**.

75.43.4 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Event Notification	
Raise event when virtual machine is powered on?	Select **Yes** to raise an event when a virtual machine is in the "powered on" state. The default is Yes.
Event severity when virtual machine is powered on	Set the event severity level, from 1 to 40, to indicate the importance of an event in which a virtual machine is in the "powered on" state. The default is 15.
Raise event when virtual machine is powered off?	Select **Yes** to raise an event when a virtual machine is in the "powered off" state. The default is Yes.
Event severity when virtual machine is powered off	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the virtual machine is in the "powered off" state. The default is 15.
Raise event when virtual machine is suspended?	Select **Yes** to raise an event when a virtual machine is in "suspended" state. The default is Yes.

Parameter	How to Set It
Event severity when virtual machine is suspended	Set the event severity level, from 1 to 40, to indicate the importance of an event in which a virtual machine is in “suspended” state. The default is 15.
Raise event when status information is not available?	Select **Yes** to raise an event when information about the virtual machine’s connection status is not available. The default is unselected.
Event severity when status information is not available	Set the event severity level, from 1 to 40, to indicate the importance of an event in which information about the virtual machine’s connection status is not available. The default is 15.
Event severity when AppManager failed to get metrics	Set the event severity level, from 1 to 40, to indicate the importance of an event in which AppManager failed to retrieve metrics from vCenter. The default is 15.
Event severity when AppManager failed to log in	Set the event severity level, from 1 to 40, to indicate the importance of an event in which AppManager failed to log in to vCenter. The default is 5.
Event severity when VmPowerStatus job fails unexpectedly	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the VmPowerStatus job fails unexpectedly. The default is 5.
Actions	
When a powered on event is raised, perform this action	Choose to **power off**, **suspend**, or take **no action** when an event is raised because the virtual machine is in “powered on” state. The default is no action.
When a powered off event is raised, perform this action	Choose to **power on** or take **no action** when an event is raised because the virtual machine is in “powered off” state. The default is power on.
When a suspended event is raised, perform this action	Choose to **resume** or take **no action** when an event is raised because the virtual machine is in “suspended” state. The default is no action.

75.44 VmSnapshotUsage

Use this Knowledge Script to monitor virtual machine snapshots. This script raises an event when the number of all snapshots, the size of all snapshots, or the age of a snapshot or a reverted snapshot exceed the thresholds you set. This script generates data streams for the number of all snapshots, the size of all snapshots, and the age of a snapshot or a reverted snapshot.

NOTE: This script will not generate events for virtual machines that have a parent host in maintenance mode.

75.44.1 Resource Object

vSphere virtual machine

75.44.2 Default Schedule

By default, this script runs **daily.**

75.44.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Job Failure Notification	
Raise event when snapshot metrics are not available?	Select **Yes** to raise an event if none of your monitored virtual machines contain any snapshots. If even one of your monitored virtual machines has a snapshot, or if some snapshots are deleted, the script will *not* raise an event. The default is unselected.
Event severity when snapshot metrics are not available	Set the event severity level, from 1 to 40, to indicate the importance of an event in which none of your monitored virtual machines contain any snapshots. The default is 15.
Event severity when AppManager failed to get metrics	Set the event severity level, from 1 to 40, to indicate the importance of an event in which virtual machine snapshot metrics are not available. The default is 15.
Event severity when AppManager failed to log in	Set the event severity level, from 1 to 40, to indicate the importance of an event in which AppManager failed to log in to vCenter. The default is 5.
Event severity when VmSnapshotUsage job failed unexpectedly	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the VmUptime job fails unexpectedly. The default is 5.
Additional Settings	
Event Details	
Event detail format	Select either **HTML Table** or **Plain Text** as the format for event detail. The default is HTML Table.

Parameter	How to Set It
Monitor Snapshots	
Event Notification	
Raise event if number of snapshots exceeds threshold?	Select **Yes** to raise an event if the number of snapshots exceeds the threshold you set. The default is Yes.
Threshold – Maximum number of snapshots	Specify the maximum number of snapshots that can be present before raising an event. The default is 0.
Event severity when number of snapshots exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of snapshots exceeds the threshold. The default is 15.
Raise event if the size of all snapshots exceeds threshold?	Select **Yes** to raise an event if the size of all snapshots exceeds the threshold you set. The default is unselected.
Threshold – Maximum size of all snapshots	Specify the maximum size of all snapshots that can exist before raising an event. The default is 10 GB.
Event severity when the size of all snapshots exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the size of all snapshots exceeds the threshold. The default is 15.
Raise event if age of a snapshot exceeds threshold?	Select **Yes** to raise an event if the time between now and the time when the snapshot was first created exceeds the threshold you set. The default is unselected.
Threshold – Maximum age of a snapshot	Specify the maximum amount of time that can pass since the creation of a snapshot before raising an event. The default is 30 days.
Event severity when age of a snapshot exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the time between now and time when the snapshot was first created exceeds the threshold. The default is 15.
Raise event if the time since a snapshot was last reverted exceeds threshold?	Select **Yes** to raise an event if the time since a snapshot was last reverted exceeds the threshold. The default is unselected.
Threshold – Maximum time since a snapshot was last reverted	Specify the maximum amount of time that can pass between now and when a snapshot was last reverted before raising an event. The default is 30 days.
Event severity when the time since a snapshot was last reverted exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the time since a snapshot was last reverted exceeds the threshold. The default is 15.
Data Collection	
Collect data for the number of snapshots?	Select **Yes** to collect data about the number of all snapshots for charts and reports. The default is unselected.
Collect data for the size of all snapshots?	Select **Yes** to collect data about the size of all snapshots for charts and reports. The default is unselected.
Collect data for the age of snapshots?	Select **Yes** to collect data about the age of snapshots for charts and reports. The default is unselected.
Collect data for the age of reverted snapshots?	Select **Yes** to collect data about the age of reverted snapshots for charts and reports. The default is unselected.

75.45 VmToolsStatus

Use this Knowledge Script to monitor the status of VMware Tools for virtual machines. This script raises an event if VMware Tools have never been installed, are not running, have an outdated version, have a current version, and multiple other status values. The script also generates data streams for VMware Tools status.

NOTE:

- If the parent host of the monitored virtual machine is in maintenance mode, this Knowledge Script will not generate events.
- Using this script and other VirtualCenter_Vm* scripts to monitor a large number of virtual machines at the same time might cause the jobs to fail. If the jobs fail on a regular basis, consider running the VirtualCenter_Vm* scripts on fewer virtual machines.

75.45.1 Resource Object

vSphere virtual machine

75.45.2 Default Schedule

By default, this script runs every **1 Day**.

75.45.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Job Failure Notification	
Event severity when AppManager failed to get metrics	Set the event severity level, from 1 to 40, to indicate the importance of an event in which AppManager failed to retrieve metrics from vCenter. The default is 15.
Event severity when AppManager when failed to log in	Set the event severity level, form 1 to 40, to indicate the importance of an event in which AppManager failed to log in to vCenter. The default is 5.
Event severity when VMToolsStatus job fails unexpectedly	Set the event severity level, form 1 to 40, to indicate the importance of an event in which the VMToolsStatus job fails unexpectedly. The default is 5.
Raise event when status information is not available?	Select **Yes** to raise an event when information about the virtual machine's connection status is not available. The default is unselected.
Event severity when status information is not available	Set the event severity level, from 1 to 40, to indicate the importance of an event in which information about the virtual machine's connection status is not available. The default is 15.
Additional Settings	

Parameter	How to Set It
Event Details	
Event detail format	Select either **HTML Table** or **Plain Text** as the format for event detail. The default is HTML Table.
Monitor VMware Tools Status	
Event Notification	
Running Status	
Raise event when not installed?	Select **Yes** to raise an event when VM Tools have not been installed on the virtual machine. The default is Yes.
Event severity when not installed	Set the event severity level, from 1 to 40, to indicate the importance of an event in which VM Tools have not been installed on the virtual machine. The default is 15.
Raise event when not running?	Select **Yes** to raise an event when VMware Tools are not running on a virtual machine. The default is Yes.
Event severity when not running	Set the event severity level, from 1 to 40, to indicate the importance of an event in which VMware Tools are not running on a virtual machine. The default is 15.
Raise event when not running on powered-off virtual machine?	Select **Yes** to raise an event when VMware Tools are not running on a powered-off virtual machine. The default is Yes.
Event severity when not running on powered-off virtual machine	Set the event severity level, from 1 to 40, to indicate the importance of an event in which VMware Tools are not running on a powered-off virtual machine. The default is 5.
Version Status	
Raise event when blacklisted and needs immediate upgrade?	Select **Yes** to raise an event when VMware Tools have been blacklisted and need an immediate upgrade. The default is Yes.
Event severity when blacklisted and needs immediate upgrade	Set the event severity level, from 1 to 40, to indicate the importance of an event in which VMware Tools have been blacklisted and need an immediate upgrade. The default is 5.
Raise event when not current and not supported?	Select **Yes** to raise an event when VMware Tools are so old that they are not current and not supported. The default is Yes.
Event severity when not current and not supported	Set the event severity level, from 1 to 40, to indicate the importance of an event in which VMware Tools are not current and not supported. The default is 10.
Raise event when not current but supported?	Select **Yes** to raise an event when VMware Tools are not current but supported. The default is Yes.
Event severity when not current but supported	Set the event severity level, from 1 to 40, to indicate the importance of an event in which VMware Tools are not current but supported. The default is 15.
Raise event when not managed by VMware?	Select **Yes** to raise an event when VMware Tools are not managed by VMware. The default is Yes.
Event severity when not managed by VMware	Set the event severity level, from 1 to 40, to indicate the importance of an event in which VMware Tools are not managed by VMware. The default is 15.
Raise event when supported and newer than version on host	Select **Yes** to raise an event when VMware Tools are supported, but a newer version than the version on the host. The default is Yes.

Parameter	How to Set It
Event severity when supported and newer than version on host	Set the event severity level, from 1 to 40, to indicate the importance of an event in which VMware Tools are supported, but a newer version than the version on the host. The default is 15.
Raise event when too new to work correctly?	Select **Yes** to raise an event when VMware Tools are too new to work correctly with this module. The default is Yes.
Event severity when too new to work correctly	Set the event severity level, from 1 to 40, to indicate the importance of an event in which VMware Tools are too new to work correctly with this module. The default is 10.
Data Collection	
Collect data for VMware Tools status?	Select **Yes** to collect VMware Tools status data for charts and reports. The default is unselected. **NOTE:** If selected, the possible values are: • 0: VMware Tools are not installed • 1: VMware Tools are not running • 2: VMware Tools version is old • 3: VMware Tools are okay • 4: VMware Tools are not running on powered-off virtual machines • 5: VMware Tools are blacklisted and need an immediate upgrade • 6: VMware Tools are supported and newer than the version on the host • 7: VMware Tools are too new • 8: VMware Tools are not current and not supported • 9: VMware Tools are not managed by VMware

75.46 VmUptime

Use the VirtualCenter_VmUptime Knowledge Script to monitor virtual machine uptime in days. Virtual machine uptime is the time elapsed since the last system startup. This script raises an event when a virtual machine is rebooted, and it collects data for virtual machine uptime.

NOTE:

- If the parent host of the monitored virtual machine is in maintenance mode, this Knowledge Script will not generate events.
- The VirtualCenter_VmUptime Knowledge Script is supported on vSphere 5.0 or later.

75.46.1 Resource Object

vSphere virtual machine

75.46.2 Default Schedule

By default, this script runs every **5 minutes.**

75.46.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Job Failure Notification	
Raise event when uptime metrics are not available?	Select **Yes** to raise an event if virtual machine uptime metrics are not available. The default is unselected.
Event severity when uptime metrics are not available	Set the event severity level, from 1 to 40, to indicate the importance of an event in which uptime metrics are not available. The default is 15.
Event severity when AppManager failed to get metrics	Set the event severity level, from 1 to 40, to indicate the importance of an event in which AppManager failed to retrieve virtual machine uptime status from vCenter. The default is 15.
Event severity when AppManager failed to log in	Set the event severity level, from 1 to 40, to indicate the importance of an event in which AppManager failed to log in to vCenter. The default is 5.
Event severity when VmUptime job fails unexpectedly	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the VmUptime job fails unexpectedly. The default is 5.
Additional Settings	
Event Details	
Event detail format	Select either **HTML Table** or **Plain Text** as the format for event detail. The default is HTML Table.

Parameter	How to Set It
Monitor Uptime	
Event Notification	
Raise event if virtual machine reboots?	Select **Yes** to raise an event if the virtual machine reboots. The default is Yes.
Event severity when virtual machine reboots	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the virtual machine reboots. The default is 15.
Data Collection	
Collect data for uptime?	Select **Yes** to collect data for graphs and reports. When enabled, data collection returns a datastream for the virtual machine uptime in days. The default is unselected.

75.47 Recommended Knowledge Script Groups

You can find the VirtualCenter Knowledge Script Groups (KSGs) on the RECOMMENDED tab of the Knowledge Script pane of the Operator Console.

All the scripts in the KSGs have their parameters set to recommended values. To run all of the recommended scripts in a KSG at one time, click the RECOMMENDED tab, and then run the KSG on a VirtualCenter resource.

Run the KSG from the Master view, not the VirtualCenter view. In order to use the Discovery_VMware Knowledge Script in a monitoring policy, the view must include root objects, which are not visible in the VirtualCenter view.

The VirtualCenter KSGs enable a "best practices" usage of AppManager for monitoring your VirtualCenter environment. You can use these KSGs with AppManager monitoring policies. A monitoring policy, which lets you efficiently and consistently monitor all the resources in your environment, uses a set of pre-configured Knowledge Scripts to automatically monitor resources as they appear in the TreeView pane. For more information, see "About Policy-Based Monitoring" in the AppManager Help.

A KSG is composed of a subset of a module's Knowledge Scripts. The script that belongs to a KSG is a different copy of the original script you access from the VirtualCenter tab. If you modify a script that belongs to a KSG, the parameter settings of the original script in the VirtualCenter tab are not affected.

In some cases, default script parameter settings are different when the script is deployed as part of a KSG, as opposed to when it is deployed alone. The default settings of a script within a group depend on its monitoring purpose within the larger group, and on the intended monitoring scope of that group.

If you modify or remove a script associated with the VirtualCenter KSG and want to restore it to its original form, you can reinstall AppManager for VMware vSphere on the repository computer or check in the appropriate script from the `AppManager\qdb\kp\VirtualCenter` directory.

75.47.1 ClusterMonitor Recommended Knowledge Script Group

The following Knowledge Scripts in the AppManager for VMware vSphere module are members of the ClusterMonitor recommended KSG.

- ClusterCPUUsage
- ClusterMemUsage
- ClusterStatus

75.47.2 HostMonitor Recommended Knowledge Script Group

The following Knowledge Scripts in the AppManager for VMware vSphere module are members of the HostMonitor recommended KSG.

- DatastoreUsage
- HostConnected
- HostCPUUsage
- HostDiskIO
- HostDiskTotalLatency
- HostMemoryUsage
- HostNetworkIO

75.47.3 ResourcePoolMonitor Recommended Knowledge Script Group

The following Knowledge Scripts in the AppManager for VMware vSphere module are members of the ResourcePoolMonitor recommended KSG.

- ResourcePoolCPUUsage
- ResourcePoolMemUsage
- ResourcePoolStatus

75.47.4 VirtualCenterMonitor Recommended Knowledge Script Group

The following Knowledge Scripts in the AppManager for VMware vSphere module are members of the VirtualCenterMonitor recommended KSG.

- HostConnected
- HostCPUUsage
- HostMemoryUsage
- VmConnected
- VmCPUUsage
- VmMemoryUsage

75.47.5 VirtualMachineMonitor Recommended Knowledge Script Group

The following Knowledge Scripts in the AppManager for VMware vSphere module are members of the VirtualMachineMonitor recommended KSG.

- VmCPUUsage
- VmDiskIO
- VmDiskUsage
- VmMemoryUsage
- VmNetworkIO
- VmToolsStatus

76 VoIPQuality Knowledge Scripts

From the Knowledge Script view of Control Center, you can access more information about any NetIQ-supported Knowledge Script by selecting it and clicking **Help**. Or in the Operator Console, click any Knowledge Script in the Knowledge Script pane and press **F1**.

Knowledge Script	What It Does
CallPerf_G711a	Runs a VoIP test between Performance Endpoints for the G.711a codec.
CallPerf_G711u	Runs a VoIP test between Performance Endpoints for the G.711u codec.
CallPerf_G723.1-ACELP	Runs a VoIP test between Performance Endpoints for the G.723.1-ACELP codec.
CallPerf_G723.1-MPMLQ	Runs a VoIP test between Performance Endpoints for the G.723.1-MPMLQ codec.
CallPerf_G726	Runs a VoIP test between Performance Endpoints for the G.726 codec.
CallPerf_G729	Runs a VoIP test between Performance Endpoints for the G.729 codec.
CallPerf_G729A	Runs a VoIP test between Performance Endpoints for the G.729 Annex A codec.
CiscoSAA_G711a	Runs a VoIP test between Cisco SAA-enabled routers for the G.711a codec.
CiscoSAA_G711u	Runs a VoIP test between Cisco SAA-enabled routers for the G.711u codec.
CiscoSAA_G723.1-ACELP	Runs a VoIP test between Cisco SAA-enabled routers for the G.723.1-ACELP codec.
CiscoSAA_G723.1-MPMLQ	Runs a VoIP test between Cisco SAA-enabled routers for the G.723.1-MPMLQ codec.
CiscoSAA_G726	Runs a VoIP test between Cisco SAA-enabled routers for the G.726 codec.
CiscoSAA_G729	Runs a VoIP test between Cisco SAA-enabled routers for the G.729 codec.
CiscoSAA_G729A	Runs a VoIP test between Cisco SAA-enabled routers for the G.729 Annex A codec.
Report_Configuration	Summarizes VoIP Quality configuration information and summary information about which talkers are talking to which listeners for selected computers.
Report_GroupSummary	Summarizes group-to-group comparisons for VoIP Quality data streams.
Report_MOSAvailMatrix	Summarizes the average MOS and availability for valid talker-listener pairs.
Report_MOSSummary	Summarizes group-to-group comparisons for MOS breakdown.
Report_RvalueSummary	Summarizes group-to-group comparisons for R-value breakdown.
Report_TimeDetail	Summarizes time series charts for selected groups.
Report_VoIPQualitySummary	Summarizes VoIP quality statistics: MOS, delay, jitter, and packet loss.

76.1 CallPerf_G711a

Use this Knowledge Script to run a VoIP test between Performance Endpoints using the G.711a codec, which uses the A-law for companding, a popular standard in Europe. This script raises an event if a metric exceeds or falls below a threshold and generates data streams for network delay, MOS, R-value, delay, jitter, jitter buffer loss, and lost data.

76.1.1 Understanding Packet Loss Concealment

Packet loss concealment (PLC) is enabled by default in the G.711u and G.711a codecs. PLC describes a number of techniques for minimizing or masking the effects of data loss during a VoIP conversation. When PLC is enabled, the adverse affects of data loss are not as severe. AppManager calculates the call quality, factoring in the behavior of PLC, which is enabled by default in the CallPerf_G711a and CallPerf_G711u Knowledge Scripts.

In the following table, *packetization delay* refers to the delay these codecs introduce as they convert a signal from analog to digital; this delay is included in the MOS estimate, as is the *jitter buffer delay*, the delay introduced by the effects of buffering to reduce interarrival delay variations.

Codec	Default Data Rate	Default Datagram Size	Packetization Delay	Default Jitter Buffer Delay	Theoretical Maximum MOS
G.711u G.711a	64 kbps	20 ms	1.0 ms	2 datagrams (40 ms)	4.40
G.726	32kbps	20 ms	1.25 ms	2 datagrams (40 ms)	4.22
G.729 G.729A	8 kbps	20 ms	35.0 ms	2 datagrams (40 ms)	4.07
G.723.1-MPMLQ	6.3 kbps	30 ms	67.5 ms	3 datagrams (60 ms)	3.87
G.723.1-ACELP	5.3 kbps	30 ms	67.5 ms	3 datagrams (60 ms)	3.69

76.1.2 Resource Objects

Call Perf object

Call Perf proxy object

When you run this script on an agent computer that acts as proxy for multiple remote computers, AppManager creates only one job that drives the tests for all talkers on that computer. These tests run simultaneously. Running multiple tests at one time can take an undesirable toll on your bandwidth resources. Use the Objects tab on the Knowledge Script Properties dialog box to include or exclude remote resources from the tests.

76.1.3 Default Schedule

By default, this script runs every 15 minutes.

76.1.4 Setting Parameter Values

Set the following parameters as needed:

Parameter	How To Set It
General Settings	
Select listener(s)	Select the listener computers from the Select Desired Computers dialog box.
Collect data?	Select **Yes** to collect data about MOS, R-value, delay, jitter, jitter buffer loss, and lost data for charts and graphs. The default is Yes.
Collect network delay data?	Select **Yes** to collect data about network delay for charts and graphs. The default is unselected.
Configuration Settings	
Test duration	Specify the duration of a test event in seconds, between one and 300. The default is 60 seconds.
Service Quality	Select a DiffServ (Differentiated Services) codepoint for classifying the bits in the IP header: • **None**. Default setting. No special treatment is given to packets. • **EF0-101000**. Deprecated Expedited Flow codepoint in use by most phones. Equivalent to the TOS "CRITIC/ECP" setting reserved for voice. • **EF-101110**. Expedited Forwarding per-hop behavior (PHB) codepoint, represents the highest-priority service. • **AF-011000**. Deprecated Assured Flow per-hop behavior (PHB) codepoint, represents a medium-quality service. Equivalent to the TOS "flash" setting. • **AF11-001010** (Assured Forwarding, Class 1, low drop precedence) • **AF12 - 001100** (Assured Forwarding, Class 1, medium drop precedence) • **AF13-001110** (Assured Forwarding, Class 1, high drop precedence) • **AF2 -010010** (Assured Forwarding, Class 2, low drop precedence) • **AF22-010100** (Assured Forwarding, Class 2, medium drop precedence) • **AF23-010110** (Assured Forwarding, Class 2, high drop precedence) • **AF31 011010** (Assured Forwarding, Class 3, low drop precedence) • **AF32-011100** (Assured Forwarding, Class 3, medium drop precedence) • **AF33-011110** (Assured Forwarding, Class 3, high drop precedence) • **AF4 -100010** (Assured Forwarding, Class 4, low drop precedence) • **AF42-100100** (Assured Forwarding, Class 4, medium drop precedence) • **AF43-100110** (Assured Forwarding, Class 4, high drop precedence) • **802.1p-011** (For medium-priority traffic, often used for call setup packets) • **802.1p-101** (For high-priority traffic, recommended for VoIP data packets)
Use Service Quality in data stream legend?	Select **Yes** to allow service quality to be used in the dynamic legend for data streams. If you select Yes, the job generates unique data stream legends based on Quality of Service (QoS) settings as well as Talker endpoint (E1) and Listener endpoint (E2) settings. Analysis Center does not collapse unique data stream legends. However, Analysis Center does collapse data stream legends that are not unique, like the legends that get created if you select No for this parameter.
Voice activity rate	Specify a voice activity rate percentage. For example, enter 50 to indicate that data is being sent during 50% of a call's duration. The default is 50%.

Parameter	How To Set It
Delay between voice datagrams	Specify a delay, in milliseconds, between voice datagrams. The delay between datagrams determines the size of the datagram packets. A delay of 20 ms means that accumulated data is sent every 20 milliseconds. A smaller delay value results in smaller, more frequent datagrams that increase processing overhead; a larger delay value results in fewer, larger datagrams that increase delay. The default is 20 ms.
Use silence suppression?	Select **Yes** to enable silence suppression, which means that no data is sent during periods of “call silence” (i.e. when no one is talking). The default is unselected.
Enable packet loss concealment?	Select **Yes** to enable packet loss concealment (PLC). PLC is a technique for minimizing or masking the effects of data loss. When PLC is enabled, AppManager assumes that the quality of a conversation would be improved, but the improvement is factored into a MOS calculation **only** if data is lost. The default is Yes.
Advanced Configuration Settings	
Absolute jitter buffer size	Specify the size of the absolute jitter buffer in milliseconds. The jitter buffer size is a critical component of the MOS calculation. For example, a jitter buffer of 43 ms could hold two 20-ms datagram packets and allow for three extra milliseconds of variability. The default is 40 ms.
Additional fixed delay	Specify any additional fixed delay in milliseconds. Use this parameter to add a delay value from a known, constant source. For instance, if your test equipment adds 10 ms of delay to each datagram, enter 10 here. The default is 0 ms.
Source port number	Specify the port number of the test source computer. Accept the default of AUTO to automatically locate the port number.
Destination port number	Specify the port number of the test destination computer. Accept the default of AUTO to automatically locate the port number.
Event Notification	
Raise event if test fails?	Select **Yes** to raise an event if the VoIP test does not complete successfully. The default is Yes.
Event severity when test fails	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the VoIP test does not complete successfully. The default is 5.
Raise event if MOS/R-value falls below threshold	Select **Yes** to raise an event if the MOS score or R-value falls below the threshold that you set. The default is Yes.
VoIP quality metric for event	Select the VoIP quality metric you want to use for the VoIP test. The default is MOS. • **MOS**. The Mean Opinion Score (MOS) is an overall score representing the quality of a call. The MOS is a number between 1 and 5. A MOS of 5 is excellent; a MOS of 1 is unacceptably bad. The MOS is calculated based on measured items plus jitter buffer size. The jitter buffer size is constant based on the codec/script. Only one jitter buffer size is specified and used throughout the test. • **R-value**. A single score that is derived from delays and equipment impairment factors. An R-value can be mapped to an estimated MOS. R-values range from 100 (excellent) to 0 (poor).
Threshold - Minimum MOS	Specify the minimum Mean Opinion Score (MOS) that must be reached to prevent an event from being raised. The default is 3.60.

Parameter	How To Set It
Threshold - Minimum R-value	Specify the minimum acceptable R-value that must be reached to prevent an event from being raised. The default is 70.
Event severity when VoIP quality falls below threshold	Set a severity level, between 1 and 40, to indicate the importance of an event in which MOS or R-value falls below the threshold that you set. The default is 5.
Raise event if delay exceeds threshold?	Select **Yes** to raise an event if delay exceeds the threshold that you set. The default is Yes.
Threshold - Maximum delay	Specify the maximum amount of delay that can occur before an event is raised. The delay is calculated on each packet. The delay of the test is the average of the delay for all packets. The default is 400 ms.
Event severity when delay exceeds threshold	Set a severity level, between 1 and 40, to indicate the importance of an event in which delay exceeds the threshold that you set. The default is 15.
Raise event if jitter exceeds threshold?	Select **Yes** to raise an event if jitter exceeds the threshold that you set. The default is Yes.
Threshold - Maximum jitter	Specify the maximum amount of jitter that can occur before an event is raised. Jitter indicates the variation in packet arrival time. The jitter for the test is the average of the jitter between all packets. The default is 60 ms.
Event severity when jitter exceeds threshold	Set a severity level, between 1 and 40, to indicate the importance of an event in which jitter exceeds the threshold that you set. The default is 15.
Raise event if jitter buffer loss exceeds threshold?	Select **Yes** to raise an event if jitter buffer loss exceeds the threshold that you set. The default is Yes.
Threshold - Maximum jitter buffer loss	Specify the maximum percentage of jitter buffer loss that can occur before an event is raised. The default is 1.0%. Jitter buffer loss is the amount of data that is lost when jitter exceeds that which the jitter buffer can hold. Jitter buffer loss affects call clarity, which affects the overall MOS score.
Event severity when jitter buffer loss exceeds threshold	Set a severity level, between 1 and 40, to indicate the importance of an event in which jitter buffer loss exceeds the threshold that you set. The default is 15.
Raise event if lost data exceeds threshold?	Select **Yes** to raise an event if lost data exceeds the threshold that you set. The default is Yes.
Threshold - Maximum lost data	Specify the maximum percentage of lost data that can occur before an event is raised. The default is 1.0%. To calculate this percentage, the script divides the number of datagrams lost by the number of datagrams sent.
Event severity when lost data exceeds threshold	Set a severity level, between 1 and 40, to indicate the importance of an event in which lost data exceeds the threshold that you set. The default is 15.

76.2 CallPerf_G711u

Use this Knowledge Script to run a VoIP test between Performance Endpoints using the G.711u codec, which uses the u-law for companding, the most frequently used method in the USA. This script raises an event if a metric exceeds or falls below a threshold and generates data streams for network delay, MOS, R-value, delay, jitter, jitter buffer loss, and lost data.

76.2.1 Understanding Packet Loss Concealment

Packet loss concealment (PLC) is enabled by default in the G.711u and G.711a codecs. PLC describes a number of techniques for minimizing or masking the effects of data loss during a VoIP conversation. When PLC is enabled, the adverse affects of data loss are not as severe. AppManager calculates the call quality, factoring in the behavior of PLC, which is enabled by default in the CallPerf_G711a and CallPerf_G711u Knowledge Scripts.

In the following table, *packetization delay* refers to the delay these codecs introduce as they convert a signal from analog to digital; this delay is included in the MOS estimate, as is the *jitter buffer delay*, the delay introduced by the effects of buffering to reduce interarrival delay variations.

Codec	Default Data Rate	Default Datagram Size	Packetization Delay	Default Jitter Buffer Delay	Theoretical Maximum MOS
G.711u G.711a	64 kbps	20 ms	1.0 ms	2 datagrams (40 ms)	4.40
G.726	32kbps	20 ms	1.25 ms	2 datagrams (40 ms)	4.22
G.729 G.729A	8 kbps	20 ms	35.0 ms	2 datagrams (40 ms)	4.07
G.723.1-MPMLQ	6.3 kbps	30 ms	67.5 ms	3 datagrams (60 ms)	3.87
G.723.1-ACELP	5.3 kbps	30 ms	67.5 ms	3 datagrams (60 ms)	3.69

76.2.2 Resource Objects

Call Perf object

Call Perf proxy object

When you run this script on an agent computer that acts as proxy for multiple remote computers, AppManager creates only one job that drives the tests for all talkers on that computer. These tests run simultaneously. Running multiple tests at one time can take an undesirable toll on your bandwidth resources. Use the Objects tab on the Knowledge Script Properties dialog box to include or exclude remote resources from the tests.

76.2.3 Default Schedule

By default, this script runs every 15 minutes.

76.2.4 Setting Parameter Values

Set the following parameters as needed:

Parameter	How To Set It
General Settings	
Select listener(s)	Select the listener computers from the Select Desired Computers dialog box.
Collect data?	Select **Yes** to collect data about MOS, R-value, delay, jitter, jitter buffer loss, and lost data for charts and graphs. The default is Yes.
Collect network delay data?	Select **Yes** to collect data about network delay for charts and graphs. The default is unselected.
Configuration Settings	
Test duration	Specify the duration of a test event in seconds, between one and 300. The default is 60 seconds.
Service Quality	Select a DiffServ (Differentiated Services) codepoint for classifying the bits in the IP header: • **None**. Default setting. No special treatment is given to packets. • **EF0-101000**. Deprecated Expedited Flow codepoint in use by most phones. Equivalent to the TOS "CRITIC/ECP" setting reserved for voice. • **EF-101110**. Expedited Forwarding per-hop behavior (PHB) codepoint, represents the highest-priority service. • **AF-011000**. Deprecated Assured Flow per-hop behavior (PHB) codepoint, represents a medium-quality service. Equivalent to the TOS "flash" setting. • **AF11-001010** (Assured Forwarding, Class 1, low drop precedence) • **AF12 - 001100** (Assured Forwarding, Class 1, medium drop precedence) • **AF13-001110** (Assured Forwarding, Class 1, high drop precedence) • **AF2 -010010** (Assured Forwarding, Class 2, low drop precedence) • **AF22-010100** (Assured Forwarding, Class 2, medium drop precedence) • **AF23-010110** (Assured Forwarding, Class 2, high drop precedence) • **AF31 011010** (Assured Forwarding, Class 3, low drop precedence) • **AF32-011100** (Assured Forwarding, Class 3, medium drop precedence) • **AF33-011110** (Assured Forwarding, Class 3, high drop precedence) • **AF4 -100010** (Assured Forwarding, Class 4, low drop precedence) • **AF42-100100** (Assured Forwarding, Class 4, medium drop precedence) • **AF43-100110** (Assured Forwarding, Class 4, high drop precedence) • **802.1p-011** (For medium-priority traffic, often used for call setup packets) • **802.1p-101** (For high-priority traffic, recommended for VoIP data packets)
Use Service Quality in data stream legend?	Select **Yes** to allow service quality to be used in the dynamic legend for data streams. If you select Yes, the job generates unique data stream legends based on Quality of Service (QoS) settings as well as Talker endpoint (E1) and Listener endpoint (E2) settings. Analysis Center does not collapse unique data stream legends. However, Analysis Center does collapse data stream legends that are not unique, like the legends that get created if you select No for this parameter.
Voice activity rate	Specify a voice activity rate percentage. For example, enter 50 to indicate that data is being sent during 50% of a call's duration. The default is 50%.

Parameter	How To Set It
Delay between voice datagrams	Specify a delay, in milliseconds, between voice datagrams. The delay between datagrams determines the size of the datagram packets. A delay of 20 ms means that accumulated data is sent every 20 milliseconds. A smaller delay value results in smaller, more frequent datagrams that increase processing overhead; a larger delay value results in fewer, larger datagrams that increase delay. The default is 20 ms.
Use silence suppression?	Select **Yes** to enable silence suppression, which means that no data is sent during periods of “call silence” (i.e. when no one is talking). The default is unselected.
Enable packet loss concealment?	Select **Yes** to enable packet loss concealment (PLC). PLC is a technique for minimizing or masking the effects of data loss. When PLC is enabled, AppManager assumes that the quality of a conversation would be improved, but the improvement is factored into a MOS calculation **only** if data is lost. The default is Yes.
Advanced Configuration Settings	
Absolute jitter buffer size	Specify the size of the absolute jitter buffer in milliseconds. The jitter buffer size is a critical component of the MOS calculation. For example, a jitter buffer of 43 ms could hold two 20-ms datagram packets and allow for three extra milliseconds of variability. The default is 40 ms.
Additional fixed delay	Specify any additional fixed delay in milliseconds. Use this parameter to add a delay value from a known, constant source. For instance, if your test equipment adds 10 ms of delay to each datagram, enter 10 here. The default is 0 ms.
Source port number	Specify the port number of the test source computer. Accept the default of AUTO to automatically locate the port number.
Destination port number	Specify the port number of the test destination computer. Accept the default of AUTO to automatically locate the port number.
Event Notification	
Raise event if test fails?	Select **Yes** to raise an event if the VoIP test does not complete successfully. The default is Yes.
Event severity when test fails	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the VoIP test does not complete successfully. The default is 5.
Raise event if MOS/R-value falls below threshold	Select **Yes** to raise an event if the MOS score or R-value falls below the threshold that you set. The default is Yes.
VoIP quality metric for event	Select the VoIP quality metric you want to use for the VoIP test. The default is MOS. • **MOS**. The Mean Opinion Score (MOS) is an overall score representing the quality of a call. The MOS is a number between 1 and 5. A MOS of 5 is excellent; a MOS of 1 is unacceptably bad. The MOS is calculated based on measured items plus jitter buffer size. The jitter buffer size is constant based on the codec/script. Only one jitter buffer size is specified and used throughout the test. • **R-value**. A single score that is derived from delays and equipment impairment factors. An R-value can be mapped to an estimated MOS. R-values range from 100 (excellent) to 0 (poor).
Threshold - Minimum MOS	Specify the minimum Mean Opinion Score (MOS) that must be reached to prevent an event from being raised. The default is 3.60.

Parameter	How To Set It
Threshold - Minimum R-value	Specify the minimum acceptable R-value that must be reached to prevent an event from being raised. The default is 70.
Event severity when VoIP quality falls below threshold	Set a severity level, between 1 and 40, to indicate the importance of an event in which MOS or R-value falls below the threshold that you set. The default is 5.
Raise event if delay exceeds threshold?	Select **Yes** to raise an event if delay exceeds the threshold that you set. The default is Yes.
Threshold - Maximum delay	Specify the maximum amount of delay that can occur before an event is raised. The delay is calculated on each packet. The delay of the test is the average of the delay for all packets. The default is 400 ms.
Event severity when delay exceeds threshold	Set a severity level, between 1 and 40, to indicate the importance of an event in which delay exceeds the threshold that you set. The default is 15.
Raise event if jitter exceeds threshold?	Select **Yes** to raise an event if jitter exceeds the threshold that you set. The default is Yes.
Threshold - Maximum jitter	Specify the maximum amount of jitter that can occur before an event is raised. Jitter indicates the variation in packet arrival time. The jitter for the test is the average of the jitter between all packets. The default is 60 ms.
Event severity when jitter exceeds threshold	Set a severity level, between 1 and 40, to indicate the importance of an event in which jitter exceeds the threshold that you set. The default is 15.
Raise event if jitter buffer loss exceeds threshold?	Select **Yes** to raise an event if jitter buffer loss exceeds the threshold that you set. The default is Yes.
Threshold - Maximum jitter buffer loss	Specify the maximum percentage of jitter buffer loss that can occur before an event is raised. The default is 1.0%. Jitter buffer loss is the amount of data that is lost when jitter exceeds that which the jitter buffer can hold. Jitter buffer loss affects call clarity, which affects the overall MOS score.
Event severity when jitter buffer loss exceeds threshold	Set a severity level, between 1 and 40, to indicate the importance of an event in which jitter buffer loss exceeds the threshold that you set. The default is 15.
Raise event if lost data exceeds threshold?	Select **Yes** to raise an event if lost data exceeds the threshold that you set. The default is Yes.
Threshold - Maximum lost data	Specify the maximum percentage of lost data that can occur before an event is raised. The default is 1.0%. To calculate this percentage, the script divides the number of datagrams lost by the number of datagrams sent.
Event severity when lost data exceeds threshold	Set a severity level, between 1 and 40, to indicate the importance of an event in which lost data exceeds the threshold that you set. The default is 15.

76.3 CallPerf_G723.1-ACELP

Use this Knowledge Script to run a VoIP test between Performance Endpoints using the G.723.1-ACELP codec, which uses the conjugate structure algebraic code excited linear predictive compression (ACELP) algorithm. This script raises an event if a metric exceeds or falls below a threshold and generates data streams for network delay, MOS, R-value, delay, jitter, jitter buffer loss, and lost data.

76.3.1 Resource Objects

Call Perf object

Call Perf proxy object

When you run this script on an agent computer that acts as proxy for multiple remote computers, AppManager creates only one job that drives the tests for all talkers on that computer. These tests run simultaneously. Running multiple tests at one time can take an undesirable toll on your bandwidth resources. Use the Objects tab on the Knowledge Script Properties dialog box to include or exclude remote resources from the tests.

76.3.2 Default Schedule

By default, this script runs every 15 minutes.

76.3.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How To Set It
General Settings	
Select listener(s)	Select the listener computers from the Select Desired Computers dialog box.
Collect data?	Select **Yes** to collect data about MOS, R-value, delay, jitter, jitter buffer loss, and lost data for charts and graphs. The default is Yes.
Collect network delay data?	Select **Yes** to collect data about network delay for charts and graphs. The default is unselected.
Configuration Settings	
Test duration	Specify the duration of a test event in seconds, between one and 300. The default is 60 seconds.

Parameter	How To Set It
Service Quality	Select a DiffServ (Differentiated Services) codepoint for classifying the bits in the IP header: • **None**. Default setting. No special treatment is given to packets. • **EF0-101000**. Deprecated Expedited Flow codepoint in use by most phones. Equivalent to the TOS "CRITIC/ECP" setting reserved for voice. • **EF-101110**. Expedited Forwarding per-hop behavior (PHB) codepoint, represents the highest-priority service. • **AF-011000**. Deprecated Assured Flow per-hop behavior (PHB) codepoint, represents a medium-quality service. Equivalent to the TOS "flash" setting. • **AF11-001010** (Assured Forwarding, Class 1, low drop precedence) • **AF12 - 001100** (Assured Forwarding, Class 1, medium drop precedence) • **AF13-001110** (Assured Forwarding, Class 1, high drop precedence) • **AF2 -010010** (Assured Forwarding, Class 2, low drop precedence) • **AF22-010100** (Assured Forwarding, Class 2, medium drop precedence) • **AF23-010110** (Assured Forwarding, Class 2, high drop precedence) • **AF31 011010** (Assured Forwarding, Class 3, low drop precedence) • **AF32-011100** (Assured Forwarding, Class 3, medium drop precedence) • **AF33-011110** (Assured Forwarding, Class 3, high drop precedence) • **AF4 -100010** (Assured Forwarding, Class 4, low drop precedence) • **AF42-100100** (Assured Forwarding, Class 4, medium drop precedence) • **AF43-100110** (Assured Forwarding, Class 4, high drop precedence) • **802.1p-011** (For medium-priority traffic, often used for call setup packets) • **802.1p-101** (For high-priority traffic, recommended for VoIP data packets)
Use Service Quality in data stream legend?	Select **Yes** to allow service quality to be used in the dynamic legend for data streams. If you select Yes, the job generates unique data stream legends based on Quality of Service (QoS) settings as well as Talker endpoint (E1) and Listener endpoint (E2) settings. Analysis Center does not collapse unique data stream legends. However, Analysis Center does collapse data stream legends that are not unique, like the legends that get created if you select No for this parameter.
Voice activity rate	Specify a voice activity rate percentage. For example, enter 50 to indicate that data is being sent during 50% of a call's duration. The default is 50%.
Delay between voice datagrams	Specify a delay, in milliseconds, between voice datagrams. The delay between datagrams determines the size of the datagram packets. A delay of 20 ms means that accumulated data is sent every 20 milliseconds. A smaller delay value results in smaller, more frequent datagrams that increase processing overhead; a larger delay value results in fewer, larger datagrams that increase delay. The default is 20 ms.
Use silence suppression?	Select **Yes** to enable silence suppression, which means that no data is sent during periods of "call silence" (i.e. when no one is talking). The default is unselected.
Advanced Configuration Settings	
Absolute jitter buffer size	Specify the size of the absolute jitter buffer in milliseconds. The jitter buffer size is a critical component of the MOS calculation. For example, a jitter buffer of 43 ms could hold two 20-ms datagram packets and allow for three extra milliseconds of variability. The default is 40 ms.

Parameter	How To Set It
Additional fixed delay	Specify any additional fixed delay in milliseconds. Use this parameter to add a delay value from a known, constant source. For instance, if your test equipment adds 10 ms of delay to each datagram, enter 10 here. The default is 0 ms.
Source port number	Specify the port number of the test source computer. Accept the default of AUTO to automatically locate the port number.
Destination port number	Specify the port number of the test destination computer. Accept the default of AUTO to automatically locate the port number.
Event Notification	
Raise event if test fails?	Select **Yes** to raise an event if the VoIP test does not complete successfully. The default is Yes.
Event severity when test fails	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the VoIP test does not complete successfully. The default is 5.
Raise event if MOS/R-value falls below threshold	Select **Yes** to raise an event if the MOS score or R-value falls below the threshold that you set. The default is Yes.
VoIP quality metric for event	Select the VoIP quality metric you want to use for the VoIP test. The default is MOS. • **MOS**. The Mean Opinion Score (MOS) is an overall score representing the quality of a call. The MOS is a number between 1 and 5. A MOS of 5 is excellent; a MOS of 1 is unacceptably bad. The MOS is calculated based on measured items plus jitter buffer size. The jitter buffer size is constant based on the codec/script. Only one jitter buffer size is specified and used throughout the test. • **R-value**. A single score that is derived from delays and equipment impairment factors. An R-value can be mapped to an estimated MOS. R-values range from 100 (excellent) to 0 (poor).
Threshold - Minimum MOS	Specify the minimum Mean Opinion Score (MOS) that must be reached to prevent an event from being raised. The default is 3.60.
Threshold - Minimum R-value	Specify the minimum acceptable R-value that must be reached to prevent an event from being raised. The default is 70.
Event severity when VoIP quality falls below threshold	Set a severity level, between 1 and 40, to indicate the importance of an event in which MOS or R-value falls below the threshold that you set. The default is 5.
Raise event if delay exceeds threshold?	Select **Yes** to raise an event if delay exceeds the threshold that you set. The default is Yes.
Threshold - Maximum delay	Specify the maximum amount of delay that can occur before an event is raised. The delay is calculated on each packet. The delay of the test is the average of the delay for all packets. The default is 400 ms.
Event severity when delay exceeds threshold	Set a severity level, between 1 and 40, to indicate the importance of an event in which delay exceeds the threshold that you set. The default is 15.
Raise event if jitter exceeds threshold?	Select **Yes** to raise an event if jitter exceeds the threshold that you set. The default is Yes.
Threshold - Maximum jitter	Specify the maximum amount of jitter that can occur before an event is raised. Jitter indicates the variation in packet arrival time. The jitter for the test is the average of the jitter between all packets. The default is 60 ms.

Parameter	How To Set It
Event severity when jitter exceeds threshold	Set a severity level, between 1 and 40, to indicate the importance of an event in which jitter exceeds the threshold that you set. The default is 15.
Raise event if jitter buffer loss exceeds threshold?	Select **Yes** to raise an event if jitter buffer loss exceeds the threshold that you set. The default is Yes.
Threshold - Maximum jitter buffer loss	Specify the maximum percentage of jitter buffer loss that can occur before an event is raised. The default is 1.0%. Jitter buffer loss is the amount of data that is lost when jitter exceeds that which the jitter buffer can hold. Jitter buffer loss affects call clarity, which affects the overall MOS score.
Event severity when jitter buffer loss exceeds threshold	Set a severity level, between 1 and 40, to indicate the importance of an event in which jitter buffer loss exceeds the threshold that you set. The default is 15.
Raise event if lost data exceeds threshold?	Select **Yes** to raise an event if lost data exceeds the threshold that you set. The default is Yes.
Threshold - Maximum lost data	Specify the maximum percentage of lost data that can occur before an event is raised. The default is 1.0%. To calculate this percentage, the script divides the number of datagrams lost by the number of datagrams sent.
Event severity when lost data exceeds threshold	Set a severity level, between 1 and 40, to indicate the importance of an event in which lost data exceeds the threshold that you set. The default is 15.

76.4 CallPerf_G723.1-MPMLQ

Use this Knowledge Script to run a VoIP test between Performance Endpoints using the G.723.1-MPMLQ codec, which uses the multipulse maximum likelihood quantization (MPMLQ) compression algorithm. This script raises an event if a metric exceeds or falls below a threshold and generates data streams for network delay, MOS, R-value, delay, jitter, jitter buffer loss, and lost data.

76.4.1 Resource Objects

Call Perf object

Call Perf proxy object

When you run this script on an agent computer that acts as proxy for multiple remote computers, AppManager creates only one job that drives the tests for all talkers on that computer. These tests run simultaneously. Running multiple tests at one time can take an undesirable toll on your bandwidth resources. Use the Objects tab on the Knowledge Script Properties dialog box to include or exclude remote resources from the tests.

76.4.2 Default Schedule

By default, this script runs every 15 minutes.

76.4.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How To Set It
General Settings	
Select listener(s)	Select the listener computers from the Select Desired Computers dialog box.
Collect data?	Select **Yes** to collect data about MOS, R-value, delay, jitter, jitter buffer loss, and lost data for charts and graphs. The default is Yes.
Collect network delay data?	Select **Yes** to collect data about network delay for charts and graphs. The default is unselected.
Configuration Settings	
Test duration	Specify the duration of a test event in seconds, between one and 300. The default is 60 seconds.

Parameter	How To Set It
Service Quality	Select a DiffServ (Differentiated Services) codepoint for classifying the bits in the IP header: • **None**. Default setting. No special treatment is given to packets. • **EF0-101000**. Deprecated Expedited Flow codepoint in use by most phones. Equivalent to the TOS "CRITIC/ECP" setting reserved for voice. • **EF-101110**. Expedited Forwarding per-hop behavior (PHB) codepoint, represents the highest-priority service. • **AF-011000**. Deprecated Assured Flow per-hop behavior (PHB) codepoint, represents a medium-quality service. Equivalent to the TOS "flash" setting. • **AF11-001010** (Assured Forwarding, Class 1, low drop precedence) • **AF12 - 001100** (Assured Forwarding, Class 1, medium drop precedence) • **AF13-001110** (Assured Forwarding, Class 1, high drop precedence) • **AF2 -010010** (Assured Forwarding, Class 2, low drop precedence) • **AF22-010100** (Assured Forwarding, Class 2, medium drop precedence) • **AF23-010110** (Assured Forwarding, Class 2, high drop precedence) • **AF31 011010** (Assured Forwarding, Class 3, low drop precedence) • **AF32-011100** (Assured Forwarding, Class 3, medium drop precedence) • **AF33-011110** (Assured Forwarding, Class 3, high drop precedence) • **AF4 -100010** (Assured Forwarding, Class 4, low drop precedence) • **AF42-100100** (Assured Forwarding, Class 4, medium drop precedence) • **AF43-100110** (Assured Forwarding, Class 4, high drop precedence) • **802.1p-011** (For medium-priority traffic, often used for call setup packets) • **802.1p-101** (For high-priority traffic, recommended for VoIP data packets)
Use Service Quality in data stream legend?	Select **Yes** to allow service quality to be used in the dynamic legend for data streams. If you select Yes, the job generates unique data stream legends based on Quality of Service (QoS) settings as well as Talker endpoint (E1) and Listener endpoint (E2) settings. Analysis Center does not collapse unique data stream legends. However, Analysis Center does collapse data stream legends that are not unique, like the legends that get created if you select No for this parameter.
Voice activity rate	Specify a voice activity rate percentage. For example, enter 50 to indicate that data is being sent during 50% of a call's duration. The default is 50%.
Delay between voice datagrams	Specify a delay, in milliseconds, between voice datagrams. The delay between datagrams determines the size of the datagram packets. A delay of 20 ms means that accumulated data is sent every 20 milliseconds. A smaller delay value results in smaller, more frequent datagrams that increase processing overhead; a larger delay value results in fewer, larger datagrams that increase delay. The default is 20 ms.
Use silence suppression?	Select **Yes** to enable silence suppression, which means that no data is sent during periods of "call silence" (i.e. when no one is talking). The default is unselected.
Advanced Configuration Settings	
Absolute jitter buffer size	Specify the size of the absolute jitter buffer in milliseconds. The jitter buffer size is a critical component of the MOS calculation. For example, a jitter buffer of 43 ms could hold two 20-ms datagram packets and allow for three extra milliseconds of variability. The default is 40 ms.

Parameter	How To Set It
Additional fixed delay	Specify any additional fixed delay in milliseconds. Use this parameter to add a delay value from a known, constant source. For instance, if your test equipment adds 10 ms of delay to each datagram, enter 10 here. The default is 0 ms.
Source port number	Specify the port number of the test source computer. Accept the default of AUTO to automatically locate the port number.
Destination port number	Specify the port number of the test destination computer. Accept the default of AUTO to automatically locate the port number.
Event Notification	
Raise event if test fails?	Select **Yes** to raise an event if the VoIP test does not complete successfully. The default is Yes.
Event severity when test fails	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the VoIP test does not complete successfully. The default is 5.
Raise event if MOS/R-value falls below threshold	Select **Yes** to raise an event if the MOS score or R-value falls below the threshold that you set. The default is Yes.
VoIP quality metric for event	Select the VoIP quality metric you want to use for the VoIP test. The default is MOS. • **MOS**. The Mean Opinion Score (MOS) is an overall score representing the quality of a call. The MOS is a number between 1 and 5. A MOS of 5 is excellent; a MOS of 1 is unacceptably bad. The MOS is calculated based on measured items plus jitter buffer size. The jitter buffer size is constant based on the codec/script. Only one jitter buffer size is specified and used throughout the test. • **R-value**. A single score that is derived from delays and equipment impairment factors. An R-value can be mapped to an estimated MOS. R-values range from 100 (excellent) to 0 (poor).
Threshold - Minimum MOS	Specify the minimum Mean Opinion Score (MOS) that must be reached to prevent an event from being raised. The default is 3.60.
Threshold - Minimum R-value	Specify the minimum acceptable R-value that must be reached to prevent an event from being raised. The default is 70.
Event severity when VoIP quality falls below threshold	Set a severity level, between 1 and 40, to indicate the importance of an event in which MOS or R-value falls below the threshold that you set. The default is 5.
Raise event if delay exceeds threshold?	Select **Yes** to raise an event if delay exceeds the threshold that you set. The default is Yes.
Threshold - Maximum delay	Specify the maximum amount of delay that can occur before an event is raised. The delay is calculated on each packet. The delay of the test is the average of the delay for all packets. The default is 400 ms.
Event severity when delay exceeds threshold	Set a severity level, between 1 and 40, to indicate the importance of an event in which delay exceeds the threshold that you set. The default is 15.
Raise event if jitter exceeds threshold?	Select **Yes** to raise an event if jitter exceeds the threshold that you set. The default is Yes.
Threshold - Maximum jitter	Specify the maximum amount of jitter that can occur before an event is raised. Jitter indicates the variation in packet arrival time. The jitter for the test is the average of the jitter between all packets. The default is 60 ms.

Parameter	How To Set It
Event severity when jitter exceeds threshold	Set a severity level, between 1 and 40, to indicate the importance of an event in which jitter exceeds the threshold that you set. The default is 15.
Raise event if jitter buffer loss exceeds threshold?	Select **Yes** to raise an event if jitter buffer loss exceeds the threshold that you set. The default is Yes.
Threshold - Maximum jitter buffer loss	Specify the maximum percentage of jitter buffer loss that can occur before an event is raised. The default is 1.0%. Jitter buffer loss is the amount of data that is lost when jitter exceeds that which the jitter buffer can hold. Jitter buffer loss affects call clarity, which affects the overall MOS score.
Event severity when jitter buffer loss exceeds threshold	Set a severity level, between 1 and 40, to indicate the importance of an event in which jitter buffer loss exceeds the threshold that you set. The default is 15.
Raise event if lost data exceeds threshold?	Select **Yes** to raise an event if lost data exceeds the threshold that you set. The default is Yes.
Threshold - Maximum lost data	Specify the maximum percentage of lost data that can occur before an event is raised. The default is 1.0%. To calculate this percentage, the script divides the number of datagrams lost by the number of datagrams sent.
Event severity when lost data exceeds threshold	Set a severity level, between 1 and 40, to indicate the importance of an event in which lost data exceeds the threshold that you set. The default is 15.

76.5 CallPerf_G726

Use this Knowledge Script to run a VoIP test between Performance Endpoints using the G.726 codec, a waveform coder that uses Adaptive Differential Pulse Code Modulation (ADPCM). ADPCM is a variation of pulse code modulation (PCM), which sends only the difference between two adjacent samples, producing a lower bit rate. This script raises an event if a metric exceeds or falls below a threshold and generates data streams for network delay, MOS, R-value, delay, jitter, jitter buffer loss, and lost data.

76.5.1 Resource Objects

Call Perf object

Call Perf proxy object

When you run this script on an agent computer that acts as proxy for multiple remote computers, AppManager creates only one job that drives the tests for all talkers on that computer. These tests run simultaneously. Running multiple tests at one time can take an undesirable toll on your bandwidth resources. Use the Objects tab on the Knowledge Script Properties dialog box to include or exclude remote resources from the tests.

76.5.2 Default Schedule

By default, this script runs every 15 minutes.

76.5.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How To Set It
General Settings	
Select listener(s)	Select the listener computers from the Select Desired Computers dialog box.
Collect data?	Select **Yes** to collect data about MOS, R-value, delay, jitter, jitter buffer loss, and lost data for charts and graphs. The default is Yes.
Collect network delay data?	Select **Yes** to collect data about network delay for charts and graphs. The default is unselected.
Configuration Settings	
Test duration	Specify the duration of a test event in seconds, between one and 300. The default is 60 seconds.

Parameter	How To Set It
Service Quality	Select a DiffServ (Differentiated Services) codepoint for classifying the bits in the IP header: • **None**. Default setting. No special treatment is given to packets. • **EF0-101000**. Deprecated Expedited Flow codepoint in use by most phones. Equivalent to the TOS "CRITIC/ECP" setting reserved for voice. • **EF-101110**. Expedited Forwarding per-hop behavior (PHB) codepoint, represents the highest-priority service. • **AF-011000**. Deprecated Assured Flow per-hop behavior (PHB) codepoint, represents a medium-quality service. Equivalent to the TOS "flash" setting. • **AF11-001010** (Assured Forwarding, Class 1, low drop precedence) • **AF12 - 001100** (Assured Forwarding, Class 1, medium drop precedence) • **AF13-001110** (Assured Forwarding, Class 1, high drop precedence) • **AF2 -010010** (Assured Forwarding, Class 2, low drop precedence) • **AF22-010100** (Assured Forwarding, Class 2, medium drop precedence) • **AF23-010110** (Assured Forwarding, Class 2, high drop precedence) • **AF31 011010** (Assured Forwarding, Class 3, low drop precedence) • **AF32-011100** (Assured Forwarding, Class 3, medium drop precedence) • **AF33-011110** (Assured Forwarding, Class 3, high drop precedence) • **AF4 -100010** (Assured Forwarding, Class 4, low drop precedence) • **AF42-100100** (Assured Forwarding, Class 4, medium drop precedence) • **AF43-100110** (Assured Forwarding, Class 4, high drop precedence) • **802.1p-011** (For medium-priority traffic, often used for call setup packets) • **802.1p-101** (For high-priority traffic, recommended for VoIP data packets)
Use Service Quality in data stream legend?	Select **Yes** to allow service quality to be used in the dynamic legend for data streams. If you select Yes, the job generates unique data stream legends based on Quality of Service (QoS) settings as well as Talker endpoint (E1) and Listener endpoint (E2) settings. Analysis Center does not collapse unique data stream legends. However, Analysis Center does collapse data stream legends that are not unique, like the legends that get created if you select No for this parameter.
Voice activity rate	Specify a voice activity rate percentage. For example, enter 50 to indicate that data is being sent during 50% of a call's duration. The default is 50%.
Delay between voice datagrams	Specify a delay, in milliseconds, between voice datagrams. The delay between datagrams determines the size of the datagram packets. A delay of 20 ms means that accumulated data is sent every 20 milliseconds. A smaller delay value results in smaller, more frequent datagrams that increase processing overhead; a larger delay value results in fewer, larger datagrams that increase delay. The default is 20 ms.
Use silence suppression?	Select **Yes** to enable silence suppression, which means that no data is sent during periods of "call silence" (i.e. when no one is talking). The default is unselected.
Advanced Configuration Settings	
Absolute jitter buffer size	Specify the size of the absolute jitter buffer in milliseconds. The jitter buffer size is a critical component of the MOS calculation. For example, a jitter buffer of 43 ms could hold two 20-ms datagram packets and allow for three extra milliseconds of variability. The default is 40 ms.

Parameter	How To Set It
Additional fixed delay	Specify any additional fixed delay in milliseconds. Use this parameter to add a delay value from a known, constant source. For instance, if your test equipment adds 10 ms of delay to each datagram, enter 10 here. The default is 0 ms.
Source port number	Specify the port number of the test source computer. Accept the default of AUTO to automatically locate the port number.
Destination port number	Specify the port number of the test destination computer. Accept the default of AUTO to automatically locate the port number.
Event Notification	
Raise event if test fails?	Select **Yes** to raise an event if the VoIP test does not complete successfully. The default is Yes.
Event severity when test fails	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the VoIP test does not complete successfully. The default is 5.
Raise event if MOS/R-value falls below threshold	Select **Yes** to raise an event if the MOS score or R-value falls below the threshold that you set. The default is Yes.
VoIP quality metric for event	Select the VoIP quality metric you want to use for the VoIP test. The default is MOS. • **MOS**. The Mean Opinion Score (MOS) is an overall score representing the quality of a call. The MOS is a number between 1 and 5. A MOS of 5 is excellent; a MOS of 1 is unacceptably bad. The MOS is calculated based on measured items plus jitter buffer size. The jitter buffer size is constant based on the codec/script. Only one jitter buffer size is specified and used throughout the test. • **R-value**. A single score that is derived from delays and equipment impairment factors. An R-value can be mapped to an estimated MOS. R-values range from 100 (excellent) to 0 (poor).
Threshold - Minimum MOS	Specify the minimum Mean Opinion Score (MOS) that must be reached to prevent an event from being raised. The default is 3.60.
Threshold - Minimum R-value	Specify the minimum acceptable R-value that must be reached to prevent an event from being raised. The default is 70.
Event severity when VoIP quality falls below threshold	Set a severity level, between 1 and 40, to indicate the importance of an event in which MOS or R-value falls below the threshold that you set. The default is 5.
Raise event if delay exceeds threshold?	Select **Yes** to raise an event if delay exceeds the threshold that you set. The default is Yes.
Threshold - Maximum delay	Specify the maximum amount of delay that can occur before an event is raised. The delay is calculated on each packet. The delay of the test is the average of the delay for all packets. The default is 400 ms.
Event severity when delay exceeds threshold	Set a severity level, between 1 and 40, to indicate the importance of an event in which delay exceeds the threshold that you set. The default is 15.
Raise event if jitter exceeds threshold?	Select **Yes** to raise an event if jitter exceeds the threshold that you set. The default is Yes.
Threshold - Maximum jitter	Specify the maximum amount of jitter that can occur before an event is raised. Jitter indicates the variation in packet arrival time. The jitter for the test is the average of the jitter between all packets. The default is 60 ms.

Parameter	How To Set It
Event severity when jitter exceeds threshold	Set a severity level, between 1 and 40, to indicate the importance of an event in which jitter exceeds the threshold that you set. The default is 15.
Raise event if jitter buffer loss exceeds threshold?	Select **Yes** to raise an event if jitter buffer loss exceeds the threshold that you set. The default is Yes.
Threshold - Maximum jitter buffer loss	Specify the maximum percentage of jitter buffer loss that can occur before an event is raised. The default is 1.0%. Jitter buffer loss is the amount of data that is lost when jitter exceeds that which the jitter buffer can hold. Jitter buffer loss affects call clarity, which affects the overall MOS score.
Event severity when jitter buffer loss exceeds threshold	Set a severity level, between 1 and 40, to indicate the importance of an event in which jitter buffer loss exceeds the threshold that you set. The default is 15.
Raise event if lost data exceeds threshold?	Select **Yes** to raise an event if lost data exceeds the threshold that you set. The default is Yes.
Threshold - Maximum lost data	Specify the maximum percentage of lost data that can occur before an event is raised. The default is 1.0%. To calculate this percentage, the script divides the number of datagrams lost by the number of datagrams sent.
Event severity when lost data exceeds threshold	Set a severity level, between 1 and 40, to indicate the importance of an event in which lost data exceeds the threshold that you set. The default is 15.

76.6 CallPerf_G729

Use this Knowledge Script to run a VoIP test between Performance Endpoints using the G.729 codec, which offers compression with high quality. This script raises an event if a metric exceeds or falls below a threshold and generates data streams for network delay, MOS, R-value, delay, jitter, jitter buffer loss, and lost data.

76.6.1 Resource Objects

Call Perf object

Call Perf proxy object

When you run this script on an agent computer that acts as proxy for multiple remote computers, AppManager creates only one job that drives the tests for all talkers on that computer. These tests run simultaneously. Running multiple tests at one time can take an undesirable toll on your bandwidth resources. Use the Objects tab on the Knowledge Script Properties dialog box to include or exclude remote resources from the tests.

76.6.2 Default Schedule

By default, this script runs every 15 minutes.

76.6.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How To Set It
General Settings	
Select listener(s)	Select the listener computers from the Select Desired Computers dialog box.
Collect data?	Select **Yes** to collect data about MOS, R-value, delay, jitter, jitter buffer loss, and lost data for charts and graphs. The default is Yes.
Collect network delay data?	Select **Yes** to collect data about network delay for charts and graphs. The default is unselected.
Configuration Settings	
Test duration	Specify the duration of a test event in seconds, between one and 300. The default is 60 seconds.

Parameter	How To Set It
Service Quality	Select a DiffServ (Differentiated Services) codepoint for classifying the bits in the IP header: • **None**. Default setting. No special treatment is given to packets. • **EF0-101000**. Deprecated Expedited Flow codepoint in use by most phones. Equivalent to the TOS "CRITIC/ECP" setting reserved for voice. • **EF-101110**. Expedited Forwarding per-hop behavior (PHB) codepoint, represents the highest-priority service. • **AF-011000**. Deprecated Assured Flow per-hop behavior (PHB) codepoint, represents a medium-quality service. Equivalent to the TOS "flash" setting. • **AF11-001010** (Assured Forwarding, Class 1, low drop precedence) • **AF12 - 001100** (Assured Forwarding, Class 1, medium drop precedence) • **AF13-001110** (Assured Forwarding, Class 1, high drop precedence) • **AF2 -010010** (Assured Forwarding, Class 2, low drop precedence) • **AF22-010100** (Assured Forwarding, Class 2, medium drop precedence) • **AF23-010110** (Assured Forwarding, Class 2, high drop precedence) • **AF31 011010** (Assured Forwarding, Class 3, low drop precedence) • **AF32-011100** (Assured Forwarding, Class 3, medium drop precedence) • **AF33-011110** (Assured Forwarding, Class 3, high drop precedence) • **AF4 -100010** (Assured Forwarding, Class 4, low drop precedence) • **AF42-100100** (Assured Forwarding, Class 4, medium drop precedence) • **AF43-100110** (Assured Forwarding, Class 4, high drop precedence) • **802.1p-011** (For medium-priority traffic, often used for call setup packets) • **802.1p-101** (For high-priority traffic, recommended for VoIP data packets)
Use Service Quality in data stream legend?	Select **Yes** to allow service quality to be used in the dynamic legend for data streams. If you select Yes, the job generates unique data stream legends based on Quality of Service (QoS) settings as well as Talker endpoint (E1) and Listener endpoint (E2) settings. Analysis Center does not collapse unique data stream legends. However, Analysis Center does collapse data stream legends that are not unique, like the legends that get created if you select No for this parameter.
Voice activity rate	Specify a voice activity rate percentage. For example, enter 50 to indicate that data is being sent during 50% of a call's duration. The default is 50%.
Delay between voice datagrams	Specify a delay, in milliseconds, between voice datagrams. The delay between datagrams determines the size of the datagram packets. A delay of 20 ms means that accumulated data is sent every 20 milliseconds. A smaller delay value results in smaller, more frequent datagrams that increase processing overhead; a larger delay value results in fewer, larger datagrams that increase delay. The default is 20 ms.
Use silence suppression?	Select **Yes** to enable silence suppression, which means that no data is sent during periods of "call silence" (i.e. when no one is talking). The default is unselected.
Advanced Configuration Settings	
Absolute jitter buffer size	Specify the size of the absolute jitter buffer in milliseconds. The jitter buffer size is a critical component of the MOS calculation. For example, a jitter buffer of 43 ms could hold two 20-ms datagram packets and allow for three extra milliseconds of variability. The default is 40 ms.

Parameter	How To Set It
Additional fixed delay	Specify any additional fixed delay in milliseconds. Use this parameter to add a delay value from a known, constant source. For instance, if your test equipment adds 10 ms of delay to each datagram, enter 10 here. The default is 0 ms.
Source port number	Specify the port number of the test source computer. Accept the default of AUTO to automatically locate the port number.
Destination port number	Specify the port number of the test destination computer. Accept the default of AUTO to automatically locate the port number.
Event Notification	
Raise event if test fails?	Select **Yes** to raise an event if the VoIP test does not complete successfully. The default is Yes.
Event severity when test fails	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the VoIP test does not complete successfully. The default is 5.
Raise event if MOS/R-value falls below threshold	Select **Yes** to raise an event if the MOS score or R-value falls below the threshold that you set. The default is Yes.
VoIP quality metric for event	Select the VoIP quality metric you want to use for the VoIP test. The default is MOS. • **MOS**. The Mean Opinion Score (MOS) is an overall score representing the quality of a call. The MOS is a number between 1 and 5. A MOS of 5 is excellent; a MOS of 1 is unacceptably bad. The MOS is calculated based on measured items plus jitter buffer size. The jitter buffer size is constant based on the codec/script. Only one jitter buffer size is specified and used throughout the test. • **R-value**. A single score that is derived from delays and equipment impairment factors. An R-value can be mapped to an estimated MOS. R-values range from 100 (excellent) to 0 (poor).
Threshold - Minimum MOS	Specify the minimum Mean Opinion Score (MOS) that must be reached to prevent an event from being raised. The default is 3.60.
Threshold - Minimum R-value	Specify the minimum acceptable R-value that must be reached to prevent an event from being raised. The default is 70.
Event severity when VoIP quality falls below threshold	Set a severity level, between 1 and 40, to indicate the importance of an event in which MOS or R-value falls below the threshold that you set. The default is 5.
Raise event if delay exceeds threshold?	Select **Yes** to raise an event if delay exceeds the threshold that you set. The default is Yes.
Threshold - Maximum delay	Specify the maximum amount of delay that can occur before an event is raised. The delay is calculated on each packet. The delay of the test is the average of the delay for all packets. The default is 400 ms.
Event severity when delay exceeds threshold	Set a severity level, between 1 and 40, to indicate the importance of an event in which delay exceeds the threshold that you set. The default is 15.
Raise event if jitter exceeds threshold?	Select **Yes** to raise an event if jitter exceeds the threshold that you set. The default is Yes.
Threshold - Maximum jitter	Specify the maximum amount of jitter that can occur before an event is raised. Jitter indicates the variation in packet arrival time. The jitter for the test is the average of the jitter between all packets. The default is 60 ms.

Parameter	How To Set It
Event severity when jitter exceeds threshold	Set a severity level, between 1 and 40, to indicate the importance of an event in which jitter exceeds the threshold that you set. The default is 15.
Raise event if jitter buffer loss exceeds threshold?	Select **Yes** to raise an event if jitter buffer loss exceeds the threshold that you set. The default is Yes.
Threshold - Maximum jitter buffer loss	Specify the maximum percentage of jitter buffer loss that can occur before an event is raised. The default is 1.0%. Jitter buffer loss is the amount of data that is lost when jitter exceeds that which the jitter buffer can hold. Jitter buffer loss affects call clarity, which affects the overall MOS score.
Event severity when jitter buffer loss exceeds threshold	Set a severity level, between 1 and 40, to indicate the importance of an event in which jitter buffer loss exceeds the threshold that you set. The default is 15.
Raise event if lost data exceeds threshold?	Select **Yes** to raise an event if lost data exceeds the threshold that you set. The default is Yes.
Threshold - Maximum lost data	Specify the maximum percentage of lost data that can occur before an event is raised. The default is 1.0%. To calculate this percentage, the script divides the number of datagrams lost by the number of datagrams sent.
Event severity when lost data exceeds threshold	Set a severity level, between 1 and 40, to indicate the importance of an event in which lost data exceeds the threshold that you set. The default is 15.

76.7 CallPerf_G729A

Use this Knowledge Script to run a VoIP test between Performance Endpoints using the G.729 Annex A codec, which offers compression with high quality. This script raises an event if a metric exceeds or falls below a threshold and generates data streams for network delay, MOS, R-value, delay, jitter, jitter buffer loss, and lost data.

76.7.1 Resource Objects

Call Perf object

Call Perf proxy object

When you run this script on an agent computer that acts as proxy for multiple remote computers, AppManager creates only one job that drives the tests for all talkers on that computer. These tests run simultaneously. Running multiple tests at one time can take an undesirable toll on your bandwidth resources. Use the Objects tab on the Knowledge Script Properties dialog box to include or exclude remote resources from the tests.

76.7.2 Default Schedule

By default, this script runs every 15 minutes.

76.7.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How To Set It
General Settings	
Select listener(s)	Select the listener computers from the Select Desired Computers dialog box.
Collect data?	Select **Yes** to collect data about MOS, R-value, delay, jitter, jitter buffer loss, and lost data for charts and graphs. The default is Yes.
Collect network delay data?	Select **Yes** to collect data about network delay for charts and graphs. The default is unselected.
Configuration Settings	
Test duration	Specify the duration of a test event in seconds, between one and 300. The default is 60 seconds.

Parameter	How To Set It
Service Quality	Select a DiffServ (Differentiated Services) codepoint for classifying the bits in the IP header: • **None**. Default setting. No special treatment is given to packets. • **EF0-101000**. Deprecated Expedited Flow codepoint in use by most phones. Equivalent to the TOS "CRITIC/ECP" setting reserved for voice. • **EF-101110**. Expedited Forwarding per-hop behavior (PHB) codepoint, represents the highest-priority service. • **AF-011000**. Deprecated Assured Flow per-hop behavior (PHB) codepoint, represents a medium-quality service. Equivalent to the TOS "flash" setting. • **AF11-001010** (Assured Forwarding, Class 1, low drop precedence) • **AF12 - 001100** (Assured Forwarding, Class 1, medium drop precedence) • **AF13-001110** (Assured Forwarding, Class 1, high drop precedence) • **AF2 -010010** (Assured Forwarding, Class 2, low drop precedence) • **AF22-010100** (Assured Forwarding, Class 2, medium drop precedence) • **AF23-010110** (Assured Forwarding, Class 2, high drop precedence) • **AF31 011010** (Assured Forwarding, Class 3, low drop precedence) • **AF32-011100** (Assured Forwarding, Class 3, medium drop precedence) • **AF33-011110** (Assured Forwarding, Class 3, high drop precedence) • **AF4 -100010** (Assured Forwarding, Class 4, low drop precedence) • **AF42-100100** (Assured Forwarding, Class 4, medium drop precedence) • **AF43-100110** (Assured Forwarding, Class 4, high drop precedence) • **802.1p-011** (For medium-priority traffic, often used for call setup packets) • **802.1p-101** (For high-priority traffic, recommended for VoIP data packets)
Use Service Quality in data stream legend?	Select **Yes** to allow service quality to be used in the dynamic legend for data streams. If you select Yes, the job generates unique data stream legends based on Quality of Service (QoS) settings as well as Talker endpoint (E1) and Listener endpoint (E2) settings. Analysis Center does not collapse unique data stream legends. However, Analysis Center does collapse data stream legends that are not unique, like the legends that get created if you select No for this parameter.
Voice activity rate	Specify a voice activity rate percentage. For example, enter 50 to indicate that data is being sent during 50% of a call's duration. The default is 50%.
Delay between voice datagrams	Specify a delay between voice datagrams. The delay determines the size of the datagram packets. A delay of 20 ms means that accumulated data is sent every 20 milliseconds. A smaller delay value results in smaller, more frequent datagrams that increase processing overhead; a larger delay value results in fewer, larger datagrams that increase delay. The default is 20 ms.
Use silence suppression?	Select **Yes** to enable silence suppression, which means that no data is sent during periods of "call silence" (i.e. when no one is talking). The default is unselected.
Advanced Configuration Settings	
Absolute jitter buffer size	Specify the size of the absolute jitter buffer in milliseconds. The jitter buffer size is a critical component of the MOS calculation. For example, a jitter buffer of 43 ms could hold two 20-ms datagram packets and allow for three extra milliseconds of variability. The default is 40 ms.

Parameter	How To Set It
Additional fixed delay	Specify any additional fixed delay in milliseconds. Use this parameter to add a delay value from a known, constant source. For instance, if your test equipment adds 10 ms of delay to each datagram, enter 10 here. The default is 0 ms.
Source port number	Specify the port number of the test source computer. Accept the default of AUTO to automatically locate the port number.
Destination port number	Specify the port number of the test destination computer. Accept the default of AUTO to automatically locate the port number.
Event Notification	
Raise event if test fails?	Select **Yes** to raise an event if the VoIP test does not complete successfully. The default is Yes.
Event severity when test fails	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the VoIP test does not complete successfully. The default is 5.
Raise event if MOS/R-value falls below threshold	Select **Yes** to raise an event if the MOS score or R-value falls below the threshold that you set. The default is Yes.
VoIP quality metric for event	Select the VoIP quality metric you want to use for the VoIP test. The default is MOS. • **MOS**. The Mean Opinion Score (MOS) is an overall score representing the quality of a call. The MOS is a number between 1 and 5. A MOS of 5 is excellent; a MOS of 1 is unacceptably bad. The MOS is calculated based on measured items plus jitter buffer size. The jitter buffer size is constant based on the codec/script. Only one jitter buffer size is specified and used throughout the test. • **R-value**. A single score that is derived from delays and equipment impairment factors. An R-value can be mapped to an estimated MOS. R-values range from 100 (excellent) to 0 (poor).
Threshold - Minimum MOS	Specify the minimum Mean Opinion Score (MOS) that must be reached to prevent an event from being raised The default is 3.60.
Threshold - Minimum R-value	Specify the minimum acceptable R-value that must be reached to prevent an event from being raised. The default is 70.
Event severity when VoIP quality falls below threshold	Set a severity level, between 1 and 40, to indicate the importance of an event in which MOS or R-value falls below the threshold that you set. The default is 5.
Raise event if delay exceeds threshold?	Select **Yes** to raise an event if delay exceeds the threshold that you set. The default is Yes.
Threshold - Maximum delay	Specify the maximum amount of delay that can occur before an event is raised. The delay is calculated on each packet. The delay of the test is the average of the delay for all packets. The default is 400 ms.
Event severity when delay exceeds threshold	Set a severity level, between 1 and 40, to indicate the importance of an event in which delay exceeds the threshold that you set. The default is 15.
Raise event if jitter exceeds threshold?	Select **Yes** to raise an event if jitter exceeds the threshold that you set. The default is Yes.
Threshold - Maximum jitter	Specify the maximum amount of jitter that can occur before an event is raised. Jitter indicates the variation in packet arrival time. The jitter for the test is the average of the jitter between all packets. The default is 60 ms.

Parameter	How To Set It
Event severity when jitter exceeds threshold	Set a severity level, between 1 and 40, to indicate the importance of an event in which jitter exceeds the threshold that you set. The default is 15.
Raise event if jitter buffer loss exceeds threshold?	Select **Yes** to raise an event if jitter buffer loss exceeds the threshold that you set. The default is Yes.
Threshold - Maximum jitter buffer loss	Specify the maximum percentage of jitter buffer loss that can occur before an event is raised. The default is 1.0%. Jitter buffer loss is the amount of data that is lost when jitter exceeds that which the jitter buffer can hold. Jitter buffer loss affects call clarity, which affects the overall MOS score.
Event severity when jitter buffer loss exceeds threshold	Set a severity level, between 1 and 40, to indicate the importance of an event in which jitter buffer loss exceeds the threshold that you set. The default is 15.
Raise event if lost data exceeds threshold?	Select **Yes** to raise an event if lost data exceeds the threshold that you set. The default is Yes.
Threshold - Maximum lost data	Specify the maximum percentage of lost data that can occur before an event is raised. The default is 1.0%. To calculate this percentage, the script divides the number of datagrams lost by the number of datagrams sent.
Event severity when lost data exceeds threshold	Set a severity level, between 1 and 40, to indicate the importance of an event in which lost data exceeds the threshold that you set. The default is 15.

76.8 CiscoSAA_G711a

Use this Knowledge Script to run a VoIP test between Cisco SAA-enabled routers using the G.711a codec, which uses the A-law for companding, a popular standard in Europe. This script raises an event if a threshold is exceeded. In addition, this script generates data streams for delay, jitter, and lost data.

76.8.1 Resource Object

Cisco SAA object

76.8.2 Default Schedule

By default, this script runs every 15 minutes.

76.8.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How To Set It
Collect data?	Select **y** to collect data about delay, jitter, and lost data for charts and graphs. The default is y.
Select target router(s)	Select the target routers (listeners) that you want to include in the VoIP test.
Threshold - Maximum delay	Specify the maximum amount of delay that can occur before an event is raised. The default is 400 ms. The delay is calculated on each packet. The delay of the test is the average of the delay for all packets.
Threshold - Maximum jitter	Specify the maximum amount of jitter that can occur before an event is raised. The default is 60 ms. Jitter indicates the variation in packet arrival time. The jitter for the test is the average of the jitter between all packets.
Threshold - Maximum lost data	Specify the maximum percentage of data that can be lost before an event is raised. The default is 1.0%. To generate this percentage, the script divides the number of datagrams lost by the number of datagrams sent.
Event severity when test fails	Set a severity level, between 1 and 40, to indicate the importance of an event in which the VoIP test fails. The default is 5. Select 0 if you do not want to raise an event.
Event severity when delay exceeds threshold	Set a severity level, between 1 and 40, to indicate the importance of an event in which delay exceeds the threshold. The default is 15. Select 0 if you do not want to raise an event.
Event severity when jitter exceeds threshold	Set a severity level, between 1 and 40, to indicate the importance of an event in which jitter exceeds the threshold. The default is 15. Select 0 if you do not want to raise an event.

Parameter	How To Set It
Event severity when lost data exceeds threshold	Set a severity level, between 1 and 40, to indicate the importance of an event in which lost data exceeds the threshold. The default is 15. Select 0 if you do not want to raise an event.
Test duration	Specify the duration of a test event in seconds. The default is 60 seconds.
Service Quality	Select a quality of service (QoS) option for the IP Type of Service (TOS) precedence bits in the IP header: • **None - 000**. This is the default setting. No special treatment is given to packets. • **DiffServAF - 011**. The DiffServ Assured Flow setting represents a medium-quality service. This setting is equivalent to the TOS "flash" setting. • **DiffServEF - 101**. The DiffServ Expedited Flow setting represents the highest-priority service. This setting is equivalent to the TOS "CRITIC/ECP" setting reserved for voice.
Source port number	Specify the port number of the test source computer. Accept the default of AUTO to automatically locate the port number.
Destination port number	Specify the port number of the test destination computer. Accept the default of AUTO to automatically locate the port number.
Delay between voice datagrams	Specify a delay in milliseconds between voice datagrams. The delay between datagrams determines the size of the datagram packets. A delay of 20 ms means that accumulated data is sent every 20 milliseconds. A smaller delay value results in smaller, more frequent datagrams that increase processing overhead; a larger delay value results in fewer, larger datagrams that increase delay. The default is 20 ms.
Additional fixed delay	Specify any additional fixed delay in milliseconds. Use this parameter to add a delay value from a known, constant source. For instance, if your test equipment adds 10 ms of delay to each datagram, enter 10 here. The default is 0 ms.

76.9 CiscoSAA_G711u

Use this Knowledge Script to run a VoIP test between Cisco SAA-enabled routers using the G.711u codec, which uses the u-law for companding, the most frequently used method in the USA. This script raises an event if a threshold is exceeded. In addition, this script generates data streams for delay, jitter, and lost data.

76.9.1 Resource Object

Cisco SAA object

76.9.2 Default Schedule

By default, this script runs every 15 minutes.

76.9.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How To Set It
Collect data?	Select **y** to collect data about delay, jitter, and lost data for charts and graphs. The default is y.
Select target router(s)	Select the target routers (listeners) that you want to include in the VoIP test.
Threshold - Maximum delay	Specify the maximum amount of delay that can occur before an event is raised. The default is 400 ms. The delay is calculated on each packet. The delay of the test is the average of the delay for all packets.
Threshold - Maximum jitter	Specify the maximum amount of jitter that can occur before an event is raised. The default is 60 ms. Jitter indicates the variation in packet arrival time. The jitter for the test is the average of the jitter between all packets.
Threshold - Maximum lost data	Specify the maximum percentage of data that can be lost before an event is raised. The default is 1.0%. To generate this percentage, the script divides the number of datagrams lost by the number of datagrams sent.
Event severity when test fails	Set a severity level, between 1 and 40, to indicate the importance of an event in which the VoIP test fails. The default is 5. Select 0 if you do not want to raise an event.
Event severity when delay exceeds threshold	Set a severity level, between 1 and 40, to indicate the importance of an event in which delay exceeds the threshold. The default is 15. Select 0 if you do not want to raise an event.
Event severity when jitter exceeds threshold	Set a severity level, between 1 and 40, to indicate the importance of an event in which jitter exceeds the threshold. The default is 15. Select 0 if you do not want to raise an event.

Parameter	How To Set It
Event severity when lost data exceeds threshold	Set a severity level, between 1 and 40, to indicate the importance of an event in which lost data exceeds the threshold. The default is 15. Select 0 if you do not want to raise an event.
Test duration	Specify the duration of a test event in seconds. The default is 60 seconds.
Service Quality	Select a quality of service (QoS) option for the IP Type of Service (TOS) precedence bits in the IP header: • **None - 000**. This is the default setting. No special treatment is given to packets. • **DiffServAF - 011**. The DiffServ Assured Flow setting represents a medium-quality service. This setting is equivalent to the TOS "flash" setting. • **DiffServEF - 101**. The DiffServ Expedited Flow setting represents the highest-priority service. This setting is equivalent to the TOS "CRITIC/ECP" setting reserved for voice.
Source port number	Specify the port number of the test source computer. Accept the default of AUTO to automatically locate the port number.
Destination port number	Specify the port number of the test destination computer. Accept the default of AUTO to automatically locate the port number.
Delay between voice datagrams	Specify a delay in milliseconds between voice datagrams. The delay between datagrams determines the size of the datagram packets. A delay of 20 ms means that accumulated data is sent every 20 milliseconds. A smaller delay value results in smaller, more frequent datagrams that increase processing overhead; a larger delay value results in fewer, larger datagrams that increase delay. The default is 20 ms.
Additional fixed delay	Specify any additional fixed delay in milliseconds. Use this parameter to add a delay value from a known, constant source. For instance, if your test equipment adds 10 ms of delay to each datagram, enter 10 here. The default is 0 ms.

76.10 CiscoSAA_G723.1-ACELP

Use this Knowledge Script to run a VoIP test between Cisco SAA-enabled routers using the G.723.1-ACELP codec, which uses the conjugate structure algebraic code excited linear predictive compression (ACELP) algorithm. This script raises an event if a threshold is exceeded. In addition, this script generates data streams for delay, jitter, and lost data.

76.10.1 Resource Object

Cisco SAA object

76.10.2 Default Schedule

By default, this script runs every 15 minutes.

76.10.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How To Set It
Collect data?	Select **y** to collect data about delay, jitter, and lost data for charts and graphs. The default is y.
Select target router(s)	Select the target routers (listeners) that you want to include in the VoIP test.
Threshold - Maximum delay	Specify the maximum amount of delay that can occur before an event is raised. The default is 400 ms. The delay is calculated on each packet. The delay of the test is the average of the delay for all packets.
Threshold - Maximum jitter	Specify the maximum amount of jitter that can occur before an event is raised. The default is 60 ms. Jitter indicates the variation in packet arrival time. The jitter for the test is the average of the jitter between all packets.
Threshold - Maximum lost data	Specify the maximum percentage of data that can be lost before an event is raised. The default is 1.0%. To generate this percentage, the script divides the number of datagrams lost by the number of datagrams sent.
Event severity when test fails	Set a severity level, between 1 and 40, to indicate the importance of an event in which the VoIP test fails. The default is 5. Select 0 if you do not want to raise an event.
Event severity when delay exceeds threshold	Set a severity level, between 1 and 40, to indicate the importance of an event in which delay exceeds the threshold. The default is 15. Select 0 if you do not want to raise an event.
Event severity when jitter exceeds threshold	Set a severity level, between 1 and 40, to indicate the importance of an event in which jitter exceeds the threshold. The default is 15. Select 0 if you do not want to raise an event.

Parameter	How To Set It
Event severity when lost data exceeds threshold	Set a severity level, between 1 and 40, to indicate the importance of an event in which lost data exceeds the threshold. The default is 15. Select 0 if you do not want to raise an event.
Test duration	Specify the duration of a test event in seconds. The default is 60 seconds.
Service Quality	Select a quality of service (QoS) option for the IP Type of Service (TOS) precedence bits in the IP header: • **None - 000**. This is the default setting. No special treatment is given to packets. • **DiffServAF - 011**. The DiffServ Assured Flow setting represents a medium-quality service. This setting is equivalent to the TOS "flash" setting. • **DiffServEF - 101**. The DiffServ Expedited Flow setting represents the highest-priority service. This setting is equivalent to the TOS "CRITIC/ECP" setting reserved for voice.
Source port number	Specify the port number of the test source computer. Accept the default of AUTO to automatically locate the port number.
Destination port number	Specify the port number of the test destination computer. Accept the default of AUTO to automatically locate the port number.
Delay between voice datagrams	Specify a delay in milliseconds between voice datagrams. The delay between datagrams determines the size of the datagram packets. A delay of 20 ms means that accumulated data is sent every 20 milliseconds. A smaller delay value results in smaller, more frequent datagrams that increase processing overhead; a larger delay value results in fewer, larger datagrams that increase delay. The default is 20 ms.
Additional fixed delay	Specify any additional fixed delay in milliseconds. Use this parameter to add a delay value from a known, constant source. For instance, if your test equipment adds 10 ms of delay to each datagram, enter 10 here. The default is 0 ms.

76.11 CiscoSAA_G723.1-MPMLQ

Use this Knowledge Script to run a VoIP test between Cisco SAA-enabled routers using the G.723.1-MPMLQ codec, which uses the multipulse maximum likelihood quantization (MPMLQ) compression algorithm. This script raises an event if a threshold is exceeded. In addition, this script generates data streams for delay, jitter, and lost data.

76.11.1 Resource Object

Cisco SAA object

76.11.2 Default Schedule

By default, this script runs every 15 minutes.

76.11.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How To Set It
Collect data?	Select **y** to collect data about delay, jitter, and lost data for charts and graphs. The default is y.
Select target router(s)	Select the target routers (listeners) that you want to include in the VoIP test.
Threshold - Maximum delay	Specify the maximum amount of delay that can occur before an event is raised. The default is 400 ms. The delay is calculated on each packet. The delay of the test is the average of the delay for all packets.
Threshold - Maximum jitter	Specify the maximum amount of jitter that can occur before an event is raised. The default is 60 ms. Jitter indicates the variation in packet arrival time. The jitter for the test is the average of the jitter between all packets.
Threshold - Maximum lost data	Specify the maximum percentage of data that can be lost before an event is raised. The default is 1.0%. To generate this percentage, the script divides the number of datagrams lost by the number of datagrams sent.
Event severity when test fails	Set a severity level, between 1 and 40, to indicate the importance of an event in which the VoIP test fails. The default is 5. Select 0 if you do not want to raise an event.
Event severity when delay exceeds threshold	Set a severity level, between 1 and 40, to indicate the importance of an event in which delay exceeds the threshold. The default is 15. Select 0 if you do not want to raise an event.
Event severity when jitter exceeds threshold	Set a severity level, between 1 and 40, to indicate the importance of an event in which jitter exceeds the threshold. The default is 15. Select 0 if you do not want to raise an event.

Parameter	How To Set It
Event severity when lost data exceeds threshold	Set a severity level, between 1 and 40, to indicate the importance of an event in which lost data exceeds the threshold. The default is 15. Select 0 if you do not want to raise an event.
Test duration	Specify the duration of a test event in seconds. The default is 60 seconds.
Service Quality	Select a quality of service (QoS) option for the IP Type of Service (TOS) precedence bits in the IP header: • **None - 000**. This is the default setting. No special treatment is given to packets. • **DiffServAF - 011**. The DiffServ Assured Flow setting represents a medium-quality service. This setting is equivalent to the TOS "flash" setting. • **DiffServEF - 101**. The DiffServ Expedited Flow setting represents the highest-priority service. This setting is equivalent to the TOS "CRITIC/ECP" setting reserved for voice.
Source port number	Specify the port number of the test source computer. Accept the default of AUTO to automatically locate the port number.
Destination port number	Specify the port number of the test destination computer. Accept the default of AUTO to automatically locate the port number.
Delay between voice datagrams	Specify a delay in milliseconds between voice datagrams. The delay between datagrams determines the size of the datagram packets. A delay of 20 ms means that accumulated data is sent every 20 milliseconds. A smaller delay value results in smaller, more frequent datagrams that increase processing overhead; a larger delay value results in fewer, larger datagrams that increase delay. The default is 20 ms.
Additional fixed delay	Specify any additional fixed delay in milliseconds. Use this parameter to add a delay value from a known, constant source. For instance, if your test equipment adds 10 ms of delay to each datagram, enter 10 here. The default is 0 ms.

76.12 CiscoSAA_G726

Use this Knowledge Script to run a VoIP test between Cisco SAA-enabled routers using the G.726 codec, a waveform coder that uses Adaptive Differential Pulse Code Modulation (ADPCM). ADPCM is a variation of pulse code modulation (PCM), which sends only the difference between two adjacent samples, producing a lower bit rate. This script raises an event if a threshold is exceeded. In addition, this script generates data streams for delay, jitter, and lost data.

76.12.1 Resource Object

Cisco SAA object

76.12.2 Default Schedule

By default, this script runs every 15 minutes.

76.12.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How To Set It
Collect data?	Select **y** to collect data about delay, jitter, and lost data for charts and graphs. The default is y.
Select target router(s)	Select the target routers (listeners) that you want to include in the VoIP test.
Threshold - Maximum delay	Specify the maximum amount of delay that can occur before an event is raised. The default is 400 ms. The delay is calculated on each packet. The delay of the test is the average of the delay for all packets.
Threshold - Maximum jitter	Specify the maximum amount of jitter that can occur before an event is raised. The default is 60 ms. Jitter indicates the variation in packet arrival time. The jitter for the test is the average of the jitter between all packets.
Threshold - Maximum lost data	Specify the maximum percentage of data that can be lost before an event is raised. The default is 1.0%. To generate this percentage, the script divides the number of datagrams lost by the number of datagrams sent.
Event severity when test fails	Set a severity level, between 1 and 40, to indicate the importance of an event in which the VoIP test fails. The default is 5. Select 0 if you do not want to raise an event.
Event severity when delay exceeds threshold	Set a severity level, between 1 and 40, to indicate the importance of an event in which delay exceeds the threshold. The default is 15. Select 0 if you do not want to raise an event.
Event severity when jitter exceeds threshold	Set a severity level, between 1 and 40, to indicate the importance of an event in which jitter exceeds the threshold. The default is 15. Select 0 if you do not want to raise an event.

Parameter	How To Set It
Event severity when lost data exceeds threshold	Set a severity level, between 1 and 40, to indicate the importance of an event in which lost data exceeds the threshold. The default is 15. Select 0 if you do not want to raise an event.
Test duration	Specify the duration of a test event in seconds. The default is 60 seconds.
Service Quality	Select a quality of service (QoS) option for the IP Type of Service (TOS) precedence bits in the IP header: • **None - 000**. This is the default setting. No special treatment is given to packets. • **DiffServAF - 011**. The DiffServ Assured Flow setting represents a medium-quality service. This setting is equivalent to the TOS "flash" setting. • **DiffServEF - 101**. The DiffServ Expedited Flow setting represents the highest-priority service. This setting is equivalent to the TOS "CRITIC/ECP" setting reserved for voice.
Source port number	Specify the port number of the test source computer. Accept the default of AUTO to automatically locate the port number.
Destination port number	Specify the port number of the test destination computer. Accept the default of AUTO to automatically locate the port number.
Delay between voice datagrams	Specify a delay in milliseconds between voice datagrams. The delay between datagrams determines the size of the datagram packets. A delay of 20 ms means that accumulated data is sent every 20 milliseconds. A smaller delay value results in smaller, more frequent datagrams that increase processing overhead; a larger delay value results in fewer, larger datagrams that increase delay. The default is 20 ms.
Additional fixed delay	Specify any additional fixed delay in milliseconds. Use this parameter to add a delay value from a known, constant source. For instance, if your test equipment adds 10 ms of delay to each datagram, enter 10 here. The default is 0 ms.

76.13 CiscoSAA_G729

Use this Knowledge Script to run a VoIP test between Cisco SAA-enabled routers using the G.729 codec, which offers compression with high quality. This script raises an event if a threshold is exceeded. In addition, this script generates data streams for delay, jitter, and lost data.

76.13.1 Resource Object

Cisco SAA object

76.13.2 Default Schedule

By default, this script runs every 15 minutes.

76.13.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How To Set It
Collect data?	Select **y** to collect data about delay, jitter, and lost data for charts and graphs. The default is y.
Select target router(s)	Select the target routers (listeners) that you want to include in the VoIP test.
Threshold - Maximum delay	Specify the maximum amount of delay that can occur before an event is raised. The default is 400 ms. The delay is calculated on each packet. The delay of the test is the average of the delay for all packets.
Threshold - Maximum jitter	Specify the maximum amount of jitter that can occur before an event is raised. The default is 60 ms. Jitter indicates the variation in packet arrival time. The jitter for the test is the average of the jitter between all packets.
Threshold - Maximum lost data	Specify the maximum percentage of data that can be lost before an event is raised. The default is 1.0%. To generate this percentage, the script divides the number of datagrams lost by the number of datagrams sent.
Event severity when test fails	Set a severity level, between 1 and 40, to indicate the importance of an event in which the VoIP test fails. The default is 5. Select 0 if you do not want to raise an event.
Event severity when delay exceeds threshold	Set a severity level, between 1 and 40, to indicate the importance of an event in which delay exceeds the threshold. The default is 15. Select 0 if you do not want to raise an event.
Event severity when jitter exceeds threshold	Set a severity level, between 1 and 40, to indicate the importance of an event in which jitter exceeds the threshold. The default is 15. Select 0 if you do not want to raise an event.

Parameter	How To Set It
Event severity when lost data exceeds threshold	Set a severity level, between 1 and 40, to indicate the importance of an event in which lost data exceeds the threshold. The default is 15. Select 0 if you do not want to raise an event.
Test duration	Specify the duration of a test event in seconds. The default is 60 seconds.
Service Quality	Select a quality of service (QoS) option for the IP Type of Service (TOS) precedence bits in the IP header: • **None - 000**. This is the default setting. No special treatment is given to packets. • **DiffServAF - 011**. The DiffServ Assured Flow setting represents a medium-quality service. This setting is equivalent to the TOS "flash" setting. • **DiffServEF - 101**. The DiffServ Expedited Flow setting represents the highest-priority service. This setting is equivalent to the TOS "CRITIC/ECP" setting reserved for voice.
Source port number	Specify the port number of the test source computer. Accept the default of AUTO to automatically locate the port number.
Destination port number	Specify the port number of the test destination computer. Accept the default of AUTO to automatically locate the port number.
Delay between voice datagrams	Specify a delay in milliseconds between voice datagrams. The delay between datagrams determines the size of the datagram packets. A delay of 20 ms means that accumulated data is sent every 20 milliseconds. A smaller delay value results in smaller, more frequent datagrams that increase processing overhead; a larger delay value results in fewer, larger datagrams that increase delay. The default is 20 ms.
Additional fixed delay	Specify any additional fixed delay in milliseconds. Use this parameter to add a delay value from a known, constant source. For instance, if your test equipment adds 10 ms of delay to each datagram, enter 10 here. The default is 0 ms.

76.14 CiscoSAA_G729A

Use this Knowledge Script to run a VoIP test between Cisco SAA-enabled routers using the G.729 Annex A codec, which offers compression with high quality. This script raises an event if a threshold is exceeded. In addition, this script generates data streams for delay, jitter, and lost data.

76.14.1 Resource Object

Cisco SAA object

76.14.2 Default Schedule

By default, this script runs every 15 minutes.

76.14.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How To Set It
Collect data?	Select **y** to collect data about delay, jitter, and lost data for charts and graphs. The default is y.
Select target router(s)	Select the target routers (listeners) that you want to include in the VoIP test.
Threshold - Maximum delay	Specify the maximum amount of delay that can occur before an event is raised. The default is 400 ms. The delay is calculated on each packet. The delay of the test is the average of the delay for all packets.
Threshold - Maximum jitter	Specify the maximum amount of jitter that can occur before an event is raised. The default is 60 ms. Jitter indicates the variation in packet arrival time. The jitter for the test is the average of the jitter between all packets.
Threshold - Maximum lost data	Specify the maximum percentage of data that can be lost before an event is raised. The default is 1.0%. To generate this percentage, the script divides the number of datagrams lost by the number of datagrams sent.
Event severity when test fails	Set a severity level, between 1 and 40, to indicate the importance of an event in which the VoIP test fails. The default is 5. Select 0 if you do not want to raise an event.
Event severity when delay exceeds threshold	Set a severity level, between 1 and 40, to indicate the importance of an event in which delay exceeds the threshold. The default is 15. Select 0 if you do not want to raise an event.
Event severity when jitter exceeds threshold	Set a severity level, between 1 and 40, to indicate the importance of an event in which jitter exceeds the threshold. The default is 15. Select 0 if you do not want to raise an event.

Parameter	How To Set It
Event severity when lost data exceeds threshold	Set a severity level, between 1 and 40, to indicate the importance of an event in which lost data exceeds the threshold. The default is 15. Select 0 if you do not want to raise an event.
Test duration	Specify the duration of a test event in seconds. The default is 60 seconds.
Service Quality	Select a quality of service (QoS) option for the IP Type of Service (TOS) precedence bits in the IP header: • **None - 000**. This is the default setting. No special treatment is given to packets. • **DiffServAF - 011**. The DiffServ Assured Flow setting represents a medium-quality service. This setting is equivalent to the TOS "flash" setting. • **DiffServEF - 101**. The DiffServ Expedited Flow setting represents the highest-priority service. This setting is equivalent to the TOS "CRITIC/ECP" setting reserved for voice.
Source port number	Specify the port number of the test source computer. Accept the default of AUTO to automatically locate the port number.
Destination port number	Specify the port number of the test destination computer. Accept the default of AUTO to automatically locate the port number.
Delay between voice datagrams	Specify a delay in milliseconds between voice datagrams. The delay between datagrams determines the size of the datagram packets. A delay of 20 ms means that accumulated data is sent every 20 milliseconds. A smaller delay value results in smaller, more frequent datagrams that increase processing overhead; a larger delay value results in fewer, larger datagrams that increase delay. The default is 20 ms.
Additional fixed delay	Specify any additional fixed delay in milliseconds. Use this parameter to add a delay value from a known, constant source. For instance, if your test equipment adds 10 ms of delay to each datagram, enter 10 here. The default is 0 ms.

76.15 Report_Configuration

Use this Knowledge Script to summarize the VoIP Quality configuration for selected computers.

76.15.1 Resource Object

Report agent

76.15.2 Default Schedule

By default, this script runs once.

76.15.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How To Set It
Data Source	
Computer selection by	Select the computers that you want to include in the report. You can select computers by category: View, Server Group, or Computer. The default is View.
Select computers	Select the view in which you want to see the results. The default is Master.
Report Settings	
Include parameter help card?	Select **y** to include a table in the report that lists parameter settings for the script. The default is y.
Select output folder	Select the name and location of the folder in which the report will be saved. The default is VoIPQuality_Configuration.
Add job ID to output folder name?	Select **y** to add the job ID to the name of the output folder. The default is n. The job ID is helpful to make the correlation between a specific instance of a Report script and the corresponding report.
Select properties	Select and enter miscellaneous report properties in the Report Properties dialog box.
Add time stamp to title	Select **y** to append a time stamp to the title of the report, making each title unique. The default is n. The time stamp consists of the date and time the report was generated. Adding a time stamp is useful for running consecutive iterations of the same report without overwriting previous output.
Event Notification	
Raise event if report succeeds?	This script automatically raises an event if the report is not generated successfully. Select **y** to raise an event when the report is generated successfully. The default is y.
Event severity when report succeeds	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report is successful. The default is 35.

Parameter	How To Set It
Event severity when report has no data	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report contains no data. The default is 25.
Event severity when report fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report fails. The default is 5.

76.16 Report_GroupSummary

Use this Knowledge Script to summarize average VoIP Quality data stream values (MOS, R-value, availability, delay, jitter, jitter buffer loss, lost data) for a specified period.

76.16.1 Resource Object

Report agent

76.16.2 Default Schedule

By default, this script runs once.

76.16.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How To Set It
Data Source	
Values grouped by	Select the category by which you want to group data for display in the report. The default is Talker.
Select Knowledge Script(s)	Select the Knowledge Scripts that generated the data that you want to include in the report.
Computer selection by	Select the category by which you want to select the computers that you want to include in the report: View, Server Group, or Computer. The default is View.
Select computers	Select the computers that you want to include in the report.
Select time range	Select a **Specific** or **Sliding** date/time range from which the report should pull data. The default is Sliding.
Chart Thresholds	
MOS threshold	Specify the MOS threshold to display on the MOS charts in the report. The default is 0.000.
R-value threshold	Specify the R-value threshold to display on the R-value charts in the report. The default is 0.000.
Availability threshold	Specify the Availability threshold to display on the Availability charts in the report. The default is 0%.
Delay threshold	Specify the Delay threshold to display on the Delay charts in the report. The default is 0 ms.
Jitter threshold	Specify the Jitter threshold to display on the Jitter charts in the report. The default is 0 ms.
Percent Jitter Buffer Loss threshold	Specify the Jitter Buffer Loss threshold to display on the Jitter Buffer Loss charts in the report. The default is 0.000%.
Percent Lost Data threshold	Specify the Lost Data threshold to display on the Percent Lost Data charts in the report. The default is 0.000%.

Parameter	How To Set It
Report Settings	
Include parameter card?	Select **y** to include a table in the report that lists parameter settings for the report script. The default is y.
Include charts?	Select **y** to include a chart in the report. The default is y.
Include table?	Select **y** to include a table of information in the report. The default is y.
Select chart style	Select and enter chart properties in the Chart Settings dialog box. The default style is Bar.
Select output folder	Select the name and location of the folder in which the report will be saved. The default name is VoIPQualityGroupSum.
Add job ID to output folder name?	Select **y** to add the job ID to the name of the output folder. The default is n. The job ID is helpful for making the correlation between a specific instance of a Report script and the corresponding report.
Select properties	Select and enter report properties in the Report Properties dialog box. The default name is VoIP Quality Group Summary.
Add time stamp to title	Select **y** to append a time stamp to the title of the report, making each title unique. The default is n. The time stamp consists of the date and time the report was generated. Adding a time stamp is useful for running consecutive iterations of the same report without overwriting previous output.
Event Notification	
Raise event if report succeeds?	This script automatically raises an event if the report is not generated successfully. Select **y** to raise an event when the report is generated successfully. The default is y.
Event severity when report succeeds	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report is successful. The default is 35.
Event severity when report has no data	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report contains no data. The default is 25.
Event severity when report fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report fails. The default is 5.

76.17 Report_MOSAvailMatrix

Use this Knowledge Script to summarize average MOS and availability between a talker and a listener within a selected period.

76.17.1 Resource Object

Report agent

76.17.2 Default Schedule

By default, this script runs once.

76.17.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How To Set It
Data Source	
Select Knowledge Script(s)	Select the Knowledge Scripts that generated the data that you want to include in the report.
Computer selection by	Select the category by which you want to select the computers that you want to include in the report: View, Server Group, or Computer. The default is View.
Select computers	Select the computers that you want to include in the report.
Select time range	Select a **Specific** or **Sliding** date/time range from which the report should pull data. The default is Sliding.
Report Settings	
Decimal accuracy for % values	Specify the number of decimal places that you want to see in the percentage values generated by this report. The default is 3.
Include parameter card?	Select **y** to include a table in the report that lists parameter settings for the report script. The default is y.
Select output folder	Select the name and location of the folder in which the report will be output. The default name is VoIPQuality_MOSAvailMatrix
Add job ID to output folder name?	Select **y** to add the job ID to the name of the output folder. The default is n. The job is helpful for making the correlation between a specific instance of a Report script and the corresponding report.
Select properties	Select and enter report properties in the Report Properties dialog box. The default report name is VoIP Quality MOS - Availability Matrix.
Add time stamp to title	Select **y** to append a time stamp to the title of the report, making each title unique. The default is n. The time stamp consists of the date and time the report was generated. Adding a time stamp is useful for running consecutive iterations of the same report without overwriting previous output.

Parameter	How To Set It
Event Notification	
Raise event if report succeeds?	This script automatically raises an event if the report is not generated successfully. Select **y** to raise an event when the report is generated successfully. The default is y.
Event severity when report succeeds	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report is generated successfully. The default is 35.
Event severity when report has no data	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report contains no data. The default is 25.
Event severity when report fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report fails. The default is 5.

76.18 Report_MOSSummary

Use this Knowledge Script to summarize average MOS quality within a group within a selected time range.

76.18.1 Resource Object

Report agent

76.18.2 Default Schedule

By default, this script runs once.

76.18.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How To Set It
Data Source	
Calls grouped by	Select the category by which you want to group data for display in the report. The default is Talker.
Select Knowledge Script(s)	Select the Knowledge Scripts that generated the data that you want to include in the report.
Computer selection by	Select the category by which you want to select the computers that you want to include in the report: View, Server Group, or Computer. The default is View.
Select computers	Select the computers that you want to include in the report.
Select time range	Select a **Specific** or **Sliding** date/time range from which the report should pull data. The default is Sliding.
Chart Thresholds	
Good-Acceptable threshold	Specify a MOS value below which the call is acceptable and equal to or above which the call is good. This value appears on the chart as a thick horizontal line. The default is 4.030.
Acceptable-Poor threshold	Specify a MOS value below which the call is poor and above which the call is acceptable. This value appears on the chart as a thick horizontal line. The default is 3.600.
Chart Settings	
Chart size	Select the size of the rendered chart. Choose from Large, Medium, and Small. The default is Medium.
Horizontal chart?	Select **y** to create a horizontal bar chart or accept the default to create a vertical bar chart.
Chart color scheme	Select a color scheme template. The default is NetIQ.
Report Settings	

Parameter	How To Set It
Include parameter card?	Select **y** to include a table in the report that lists parameter settings for the report script. The default is y.
Include charts?	Select **y** to include a chart in the report. The default is y.
Include table?	Select **y** to include a table of information in the report. The default is y.
Select output folder	Select the name and location of the folder in which the report will be output. The default name is VoIPQualityMOSSum.
Add job ID to output folder name?	Select **y** to add the job ID to the name of the output folder. The default is n. The job ID is helpful for making the correlation between a specific instance of a Report script and the corresponding report.
Select properties	Select and enter report properties in the Report Properties dialog box. The default name is VoIP Quality MOS Summary.
Add time stamp to title	Select **y** to append a time stamp to the title of the report, making each title unique. The default is n. The time stamp consists of the date and time the report was generated. Adding a time stamp is useful for running consecutive iterations of the same report without overwriting previous output.
Event Notification	
Raise event if report succeeds?	This script automatically raises an event if the report is not generated successfully. Select **y** to raise an event when the report is generated successfully. The default is y.
Event severity when report succeeds	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report is generated successful. The default is 35.
Event severity when report has no data	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report contains no data. The default is 25.
Event severity when report fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report fails. The default is 5.

76.19 Report_RvalueSummary

Use this Knowledge Script to summarize average R-value quality within a group within a selected time range.

76.19.1 Resource Object

Report agent

76.19.2 Default Schedule

By default, this script runs once.

76.19.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How To Set It
Data Source	
Calls grouped by	Select the category by which you want to group data for display in the report. The default is Talker.
Select Knowledge Script(s)	Select the Knowledge Scripts that generated the data that you want to include in the report.
Computer selection by	Select the category by which you want to select the computers that you want to include in the report: View, Server Group, or Computer. The default is View.
Select computers	Select the computers that you want to include in the report.
Select time range	Select a **Specific** or **Sliding** date/time range from which the report should pull data. The default is Sliding.
Chart Thresholds	
Good-Acceptable threshold	Specify an R-value below which the call is acceptable and equal to or above which the call is good. This value appears on the chart as a thick horizontal line. The default is 80.0.
Acceptable-Poor threshold	Specify an R-value below which the call is poor and above which the call is acceptable. This value appears on the chart as a thick horizontal line. The default is 70.0.
Chart Settings	
Chart size	Select the size of the rendered chart. Choose from Large, Medium, and Small. The default is Medium.
Horizontal chart?	Select **y** to create a horizontal bar chart or accept the default to create a vertical bar chart.
Chart color scheme	Select a color scheme template. The default is NetIQ.
Report Settings	

Parameter	How To Set It
Include parameter card?	Select **y** to include a table in the report that lists parameter settings for the report script. The default is y.
Include charts?	Select **y** to include a chart in the report. The default is y.
Include table?	Select **y** to include a table of information in the report. The default is y.
Select output folder	Select the name and location of the folder in which the report will be output. The default name is VoIPQualityRvalueSum.
Add job ID to output folder name?	Select **y** to add the job ID to the name of the output folder. The default is n. The job ID is helpful for making the correlation between a specific instance of a Report script and the corresponding report.
Select properties	Select and enter report properties in the Report Properties dialog box. The default name is VoIP Quality R-value Summary.
Add time stamp to title	Select **y** to append a time stamp to the title of the report, making each title unique. The default is n. The time stamp consists of the date and time the report was generated. Adding a time stamp is useful for running consecutive iterations of the same report without overwriting previous output.
Event Notification	
Raise event if report succeeds?	This script automatically raises an event if the report is not generated successfully. Select **y** to raise an event when the report is generated successfully. The default is y.
Event severity when report succeeds	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report is generated successfully. The default is 35.
Event severity when report has no data	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report contains no data. The default is 25.
Event severity when report fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report fails. The default is 5.

76.20 Report_TimeDetail

Use this Knowledge Script to summarize the average values by minute of the VoIP Quality data streams (MOS, R-value, availability, delay, jitter, jitter buffer loss, lost data) within a selected period.

76.20.1 Resource Object

Report agent

76.20.2 Default Schedule

By default, this script runs once.

76.20.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How To Set It
Data Source	
Select Knowledge Scripts	Select the Knowledge Scripts that generated the data that you want to include in the report.
Computer selection by	Select the category by which you want to select the computers that you want to include in the report: View, Server Group, or Computer. The default is View.
Select computers	Select the computers that you want to include in the report.
Select time range	Select a **Specific** or **Sliding** date/time range from which the report should pull data. The default is Sliding.
Aggregate by n minutes	Specify the interval in minutes in which time data will be grouped. The default is 30 minutes.
Chart Thresholds	
MOS threshold	Specify the MOS threshold to display on the MOS charts in the report. The default is 0.000.
R-value threshold	Specify the R-value threshold to display on the R-value charts in the report. The default is 0.000.
Availability threshold	Specify the Availability threshold to display on the Availability charts in the report. The default is 0%.
Delay threshold	Specify the Delay threshold to display on the Delay charts in the report. The default is 0 ms.
Jitter threshold	Specify the Jitter threshold to display on the Jitter charts in the report. The default is 0 ms.
Percent Jitter Buffer Loss threshold	Specify the Jitter Buffer Loss threshold to display on the Jitter Buffer Loss charts in the report. The default is 0.000%.
Percent Lost Data threshold	Specify the Lost Data threshold to display on the Percent Lost Data charts in the report. The default is 0.000%.

Parameter	How To Set It
Report Settings	
Include parameter card?	Select **y** to include a table in the report that lists parameter settings for the report script. The default is y.
Include charts?	Select **y** to include a chart in the report. The default is y.
Include table?	Select **y** to include a table of information in the report. The default is y.
Select chart style	Select and enter chart properties in the Chart Settings dialog box. The default style is Line.
Select output folder	Select the name and location of the folder in which the report will be output. The default name is VoIPQualityTimeDetail.
Add job ID to output folder name?	Select **y** to add the job ID to the name of the output folder. The default is n. The job ID is helpful for making the correlation between a specific instance of a Report script and the corresponding report.
Select properties	Select and enter report properties in the Report Properties dialog box. The default name is VoIP Quality Time Detail.
Add time stamp to title	Select **y** to append a time stamp to the title of the report, making each title unique. The default is n. The time stamp consists of the date and time the report was generated. Adding a time stamp is useful for running consecutive iterations of the same report without overwriting previous output.
Event Notification	
Raise event if report succeeds?	This script automatically raises an event if the report is not generated successfully. Select **y** to raise an event when the report is generated successfully. The default is y.
Event severity when report succeeds	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report is generated successfully. The default is 35.
Event severity when report has no data	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report contains no data. The default is 25.
Event severity when report fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report fails. The default is 5.

76.21 Report_VoIPQualitySummary

Use this Knowledge Script to summarize VoIP quality statistics (MOS, R-value, delay, jitter, jitter buffer loss, and lost data) within a group within a selected period.

76.21.1 Resource Object

Report agent

76.21.2 Default Schedule

By default, this script runs once.

76.21.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How To Set It
Data Source	
Calls grouped by	Select the category by which you want to group data for display in the report. The default is Talker.
Select Knowledge Script(s)	Select the Knowledge Scripts that generated the data that you want to include in the report.
Computer selection by	Select the category by which you want to select the computers that you want to include in the report: View, Server Group, or Computer. The default is View.
Select computers	Select the computers that you want to include in the report.
Select time range	Select a **Specific** or **Sliding** date/time range from which the report should pull data. The default is Sliding.
Chart Thresholds	
Good-Acceptable MOS threshold	Specify the MOS threshold for the good-to-acceptable range to display in the report. The default is 4.030.
Acceptable-Poor MOS threshold	Specify the MOS threshold for the acceptable-to-poor range to display in the report. The default is 3.600.
Good-Acceptable R-value threshold	Specify the R-value threshold for the good-to-acceptable range to display in the report. The default is 80.0.
Acceptable-Poor R-value threshold	Specify the R-value threshold for the acceptable-to-poor range to display in the report. The default is 70.0.
Good-Acceptable delay threshold	Specify the delay threshold for the good-to-acceptable range to display in the report. The default is 150 ms.
Acceptable-Poor delay threshold	Specify the delay threshold for the acceptable-to-poor range to display in the report. The default is 400 ms.
Good-Acceptable jitter threshold	Specify the jitter threshold for the good-to-acceptable range to display in the report. The default is 40 ms.

Parameter	How To Set It
Acceptable-Poor jitter threshold	Specify the jitter threshold for the acceptable-poor range to display in the report. The default is 60 ms.
Good-Acceptable packet loss threshold	Specify the packet loss threshold for the good-acceptable range to display in the report. The default is 0.5%.
Acceptable-Poor packet loss threshold	Specify the packet loss threshold for the acceptable-poor range to display in the report. The default is 1.0%.
Good-Acceptable jitter buffer loss threshold	Specify the jitter buffer loss threshold for the good-acceptable range to display in the report. The default is 0.5%.
Acceptable-Poor jitter buffer loss threshold	Specify the jitter buffer loss threshold for the acceptable-poor range to display in the report. The default is 1.0%.
Chart Settings	
Chart size	Select the size of the rendered chart. Choose from Large, Medium, and Small. The default is Medium.
Horizontal chart?	Select **y** to create a horizontal bar chart or accept the default to create a vertical bar chart.
Chart color scheme	Select a color scheme template. The default is NetIQ.
Report Settings	
Include parameter card?	Select **y** to include a table in the report that lists parameter settings for the report script. The default is y.
Include charts?	Select **y** to include a chart in the report. The default is y.
Include table?	Select **y** to include a table of information in the report. The default is y.
Select output folder	Select the name and location of the folder in which the report will be output. The default name is VoIPQualityCallSum.
Add job ID to output folder name?	Select **y** to add the job ID to the name of the output folder. The default is n. The job ID is helpful for making the correlation between a specific instance of a Report script and the corresponding report.
Select properties	Select and enter report properties in the Report Properties dialog box. The default name is VoIP Quality Summary.
Add time stamp to title	Select **y** to append a time stamp to the title of the report, making each title unique. The default is n. The time stamp consists of the date and time the report was generated. Adding a time stamp is useful for running consecutive iterations of the same report without overwriting previous output.
Event Notification	
Raise event if report succeeds?	This script automatically raises an event if the report is not generated successfully. Select **y** to raise an event when the report is generated successfully. The default is y.
Event severity when report succeeds	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report is generated successfully. The default is 35.
Event severity when report has no data	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report contains no data. The default is 25.
Event severity when report fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the report fails. The default is 5.

76.22 Reviewing Call Performance Metrics

The VoIPQuality_CallPerf and VoIPQuality_CiscoSAA Knowledge Scripts generate data streams, based on some or all of the following call performance metrics, for use in graphs and reports.

Metric	Description
MOS	The Mean Opinion Score (MOS) is an overall score representing the quality of a call. The MOS is a number between 1 and 5. A MOS of 5 is excellent; a MOS of 1 is unacceptably bad. The MOS is calculated based on measured items plus jitter buffer size. The jitter buffer size is constant based on the codec. Jitter buffers minimize the call disruptions from delay and jitter. However, jitter buffers themselves contribute to the overall delay experienced by the call. Additionally, in situations with high network delay, jitter buffers can cause data to be lost. Thus the jitter buffer must be factored into the MOS calculation. NetIQ uses a modified version of the ITU (International Telecommunications Union) G.107 standard E-model equation to calculate the MOS. The E-model, developed by the European Telecommunications Standards Institute (ETSI), has become ITU standard G.107. This algorithm is used to evaluate the quality of a transmission by factoring in the "mouth to ear" characteristics of a speech path. **NOTE:** AppManager for Cisco SAA does not generate MOS metrics.
R-value	Defined by ITU (International Telecommunication Union) recommendation G.107, the E-model is a complex calculation, the output of which is a single score called an R-value that is derived from delays and equipment impairment factors. An R-value can be mapped to an estimated MOS. R-values range from 100 (excellent) to 0 (poor). An estimated MOS can be directly calculated from an R-value. **NOTE:** AppManager for Cisco SAA does not generate R-value metrics.
Delay	Measured in milliseconds, delay is perhaps the most common hindrance to VoIP call quality. The delay is calculated on each packet. This value includes all delay factors between the endpoints. The end-to-end delay, or latency, as measured between the endpoints is a key factor in determining voice over IP call quality. The AppManager delay measurement is taken for datagrams traveling between the endpoints in a single direction and includes the following factors: • **Network delay in one direction**—Datagram's RTP timestamp subtracted from time it was received by Endpoint 2. Endpoints must synchronize their high-precision timers to calculate one-way delay. This delay factor actually includes the propagation delay (time spent on the actual network) and the transport delay (time spent getting through intermediate network devices). • **Packetization delay**—Fixed value; dependant on selected codec. • **Jitter buffer delay**—Fixed value; dependant on type and size of configured jitter buffer. • **Additional fixed delay**—Fixed value; user-configured. Most callers notice delay when it exceeds 250ms. ITU-T standard G.114 specifies 150ms as the maximum one-way delay that is tolerable for high-quality VoIP.

Metric	Description
Jitter	As simulated calls run during a VoIP quality test, the endpoints calculate jitter, a factor known to adversely affect call quality. Jitter is also called delay variation, and it indicates the variance of the arrival rate of datagrams sent during a simulated VoIP call. When a datagram is sent, the sender (one of the endpoints) gives it a timestamp. When a datagram is received, the receiver adds another timestamp. These two timestamps are used to calculate the datagram's transit time. If the transit times for datagrams within the same call are different, the call contains jitter. In a video application, jitter manifests itself as a flickering image, while in a telephone call, its effect may be similar to the effect of packet loss: some words may be missing or garbled. The amount of jitter in a call depends on the degree of difference between the datagrams' transit times. If the transit time for all datagrams is the same (no matter how long it took for the datagrams to arrive), the call contains no jitter. If the transit times differ slightly, the call contains some jitter. Jitter values in excess of 50ms probably indicate poor call quality. They provide a short-term measurement of network congestion and can also show the effects of queuing within the network.
Jitter Buffer Loss	Jitter buffer loss is the amount of data that is lost when jitter exceeds that which the jitter buffer can hold. Jitter buffer loss affects call clarity, which affects the overall MOS score. Jitter buffers smooth out variations in calls by holding some datagrams to feed them to the application sequentially. Datagrams that are not contained by the jitter buffer due to excessive delay variation would be lost to the application and are thus called jitter buffer lost datagrams. This statistic includes datagrams with delay too great for the jitter buffer you set ("overruns") as well as those that arrive too quickly while the jitter buffer is still full and must be discarded ("underruns"). Any jitter detected in the call is compared to the size of the jitter buffer in the call script. Jitter buffer lost datagrams are then expressed as a percentage of all datagrams sent. AppManager uses the jitter buffer loss statistic when calculating a MOS for simulated VoIP traffic sent between the target devices.
Percent Lost Data	When a datagram is lost during a VoIP transmission, you can lose an entire syllable or word in a conversation. Obviously, data loss can severely impair call quality. AppManager therefore includes data loss as a call quality impairment factor in calculating the MOS of each simulated VoIP call. To measure data loss, the sending endpoint reports to the receiving endpoint how many bytes it sent, and the receiver compares that value to the amount received to determine lost data. Because *packet loss concealment* (PLC) is enabled by default in the G.711 codecs, call quality is less adversely affected if any data is lost during the VoIP test. PLC makes the codec itself more expensive to manufacture, but does not otherwise add delay or have other bad side effects.

76.23 Diagnosing VoIP Quality Problems

AppManager includes Knowledge Scripts that monitor and detect problems with VoIP quality and call quality. These scripts raise informational events as a result of the detected problems. By using NetIQ Vivinet Diagnostics and AppManager together, you have the means to diagnose more precisely any problems with VoIP quality between phones, endpoints, or other target devices such as routers and gateways.

Using an existing methodology (launching an Action script based on an event), the VoIPQuality_CallPerf Knowledge Scripts can run the Action_DiagnoseVoIPQuality Knowledge Script, which in turn launches Vivinet Diagnostics to diagnose the problem when MOS, R-value, delay, jitter, jitter buffer loss, and percentage of lost data exceed their thresholds.

The Action script runs by default only if Vivinet Diagnostics version 1.1 or later is installed on the computer on which it runs.

To enable a VoIPQuality_CallPerf Knowledge Script to launch Vivinet Diagnostics:

1. In the script's Properties dialog box, click the **Actions** tab. Action_DiagnoseVoIPQuality is selected by default.
2. Click **Properties**.
3. Enter values for all parameters. For more information about the parameter values, click **Help** on the Properties for Action_DiagnoseVoIPQuality dialog box.
4. Continue entering values on the other tabs of the Properties dialog box, or click **OK** to run the job.

76.24 Reviewing Quality of Service

In order for VoIP users to receive an acceptable level of voice quality, VoIP traffic must be given priority over other kinds of network traffic, such as data. The main goal of *Quality of Service* (QoS) is to ensure that VoIP traffic receives the preferential treatment it deserves, thereby reducing or eliminating the delay of voice packets that travel across a network.

In order to work with multiple types of network traffic, QoS first *classifies* the traffic, and then *handles* it. Once traffic is sorted into classes, QoS can determine how the traffic should be treated.

One QoS standard for sorting traffic is *DiffServ* (Differentiated Services). DiffServ sorts packets into groups that have similar QoS requirements and then gives those groups the required treatment at every hop in the network, also known as the *per-hop behavior* (PHB). DiffServ uses the second byte (eight bits) in the IP header to define and sort a packet. Of the eight bits, the last two are reserved for future use. DiffServ uses only the first six bits (the *Differentiated Services* [DS] field) in classifying a packet into one of three *codepoints*: Best Effort, Expedited Forwarding, and Assured Forwarding.

DiffServ-enabled routers can subdivide networks into DiffServ (DS) domains, within which all IP traffic competes for a finite share of bandwidth determined by a committed information rate, or CIR. To ensure that traffic that exceeds the CIR is still delivered without compromising the performance of high-priority traffic, packets within a DS domain are placed into PHB groups, including Expedited Forwarding and Assured Forwarding. Of these two groups, Expedited Forwarding receives slightly lower drop precedence and slightly higher bandwidth allocation than Assured Forwarding.

These groups allow for very exact policy-based QoS: they can be further subdivided to determine which packets are least likely to be dropped and most likely to be forwarded quickly despite congestion. Assured Forwarding includes four classes, AF1-AF4. Within each class, three subclasses may be defined, with increasing drop precedence. For example, AF1 may be the highest class of traffic, but within that class, AF13 will be dropped before AF11 or AF12.

Two DiffServ settings once used as part of the standard implementation may soon be deprecated, or rendered obsolete. Those settings, Expedited Flow and Assured Flow, used only the first three bits of the DiffServ codepoint, the type of service (TOS) bits. More recent DiffServ implementations use all six bits, for a total of 64 possible settings.

NOTE: TOS (Type of Service) is the previous name used to identify the second byte of the IP header. Used in early TCP/IP specs, TOS is described in RFC 791. In more recent TCP/IP specs, the same byte is referred to as the DS field, which is described in RFC2474.

IEEE 802.1p is an OSI Layer 2 standard for prioritizing and queuing network traffic at the data link/MAC sub-layer. It can also be defined as best-effort QoS at Layer 2. 802.1p traffic is classified and sent to the destination with no bandwidth reservation.

The three-bit Prioritization field in the 802.1p tag establishes eight levels of priority, similar to the IP Precedence bits. A level-eight priority is the highest, and is thus reserved for router-update traffic. However, AppManager supports only the two priority levels that are appropriate for VoIP traffic:

- 011–(3) For medium-priority traffic. Often used for call setup packets.
- 101–(5) For high-priority traffic. Recommended for VoIP data packets.

Network adapters and switches route traffic based on the priority level. The hardware itself-usually a NIC card or an IP phone-does the tagging. Many recently developed IP phones are marking voice packets with a priority of five (101).

NOTE: Some older switches support just two or three priority queues, so their implementation of 802.1p does not support all of the eight priority levels in the IEEE 802.1p specification. Such switches place 802.1p values of 0 through 3 in a low-priority queue, and priority levels 4 through 7 in a high-priority queue, using only two different priority levels.

When monitoring call performance with AppManager, you can run a VoIP test using a DiffServ codepoint and one of the VoIP Quality Knowledge Scripts.

77 WebLogic Server UNIX Knowledge Scripts

AppManager provides the following Knowledge Scripts for monitoring WebLogic UNIX servers.

From the Knowledge Script view of Control Center, you can access more information about any NetIQ-supported Knowledge Script by selecting it and clicking **Help**. In the Operator Console, click any Knowledge Script in the Knowledge Script pane and press **F1**.

Knowledge Script	What It Does
Availability	Monitors the availability of a WebLogic Server.
HealthCheck	Verifies that a WebLogic Server is running, can respond to requests, and can accept connections from clients.
LogAccessLog	Returns the number of entries in the WebLogic Server's `access.log` since the last sample that match the search criteria. Provides a way to monitor HTTP requests and sessions.
LogAccessLogSetPath	Sets the absolute pathname for a Web server log file.
LogWebLogic	Monitors entries that are added to the log for a WebLogic Server.
LogWebLogicSetPath	Sets the absolute pathname for a WebLogic Server log file.
Memory	Monitors the physical and virtual memory use of a WebLogic Server.
SecurityUserLockout	Monitors statistics on the number of users locked out because invalid usernames and/or passwords were supplied at login.
ServerCPU	Returns WebLogic Server CPU utilization statistics.
ServerHealthState	Returns the health state of a WebLogic Server.
ServerJVMHeap	Returns statistics on the JVM Heap.
ServerRequests	Returns statistics on the requests received by the WebLogic Server.
ServerSecurity	Monitors statistics on the number of users locked out because invalid usernames and/or passwords were supplied at login.
ServerSockets	Monitors the number of open sockets on a WebLogic Server.
ServerState	Monitors the state (`RUNNING` or not) of a WebLogic Server as reported by the WebLogic Server.
ServerUptime	Monitors how many hours a WebLogic Server has been running.
StartAdminServer	Starts a specified WebLogic Server as the Administration Server for the domain.
StartServer	Starts a specified WebLogic Server as a Managed Server.
StopServer	Stops a specified WebLogic Server, which can be either an Administration Server or a Managed Server.

77.1 Knowledge Scripts by Category

You can run Knowledge Scripts from the following categories to monitor specific services:

77.1.1 Managed Server/Cluster Knowledge Scripts

Run the following Knowledge Scripts on managed servers, the Node Manager, and clusters.

Knowledge Script	What It Does
ClusterMessage	Monitors a server's view of the members of a WebLogic cluster.
StartServerNodeMgr	Starts a WebLogic Server as a Managed Server using the Node Manager.

77.1.2 JDBC Connection Pool Knowledge Scripts

Run the following Knowledge Scripts on JDBC connection pools:

Knowledge Script	What It Does
JDBCAvailableConnections	Monitors the available number of connections in a JDBC Connection Pool.
JDBCClients	Monitors statistics on the clients of a JDBC Connection Pool.
JDBCConnectionCapacity	Monitors the current and maximum capacity of a JDBC Connection Pool.
JDBCConnections	Monitors statistics on the connections in a JDBC Connection Pool.

77.1.3 Java Message System (JMS) Knowledge Scripts

Run the following Knowledge Scripts on the JMS subsystem of a WebLogic Server:

Knowledge Script	What It Does
JMS	Monitors the number of JMS Connections in use and the number of JMS servers deployed by a WebLogic Server.
JMSConnectionsSessions	Returns statistics on the number of sessions for JMS connections.
JMSHealthState	Returns the health state of the JMS subsystem of a WebLogic Server.
JMSServersBytesStored	Returns statistics on the number of bytes stored for the JMS servers.
JMSServersDestinations	Returns statistics on the number of destinations instantiated on the JMS servers.
JMSServersHealthState	Returns the health state of the JMS Servers of a WebLogic Server.
JMSServersMsgsStored	Returns statistics on messages for the JMS servers.
JMSServersSessionPools	Returns statistics on the session pools instantiated on the JMS servers.

77.1.4 Java Virtual Machine (JVM) Knowledge Scripts

Run the following Knowledge Scripts on the JVM:

Knowledge Script	What It Does
JRockitGC	Returns statistics on the last time garbage collection was executed in the server and the total amount of time spent in garbage collection.
JRockitThreads	Returns statistics on the number of daemon threads and the total number of threads within the WebLogic Server.

77.1.5 Java Message System (JMS) Pooled Connection Knowledge Scripts

Run the following Knowledge Scripts to monitor the JMS pooled connections:

Knowledge Script	What It Does
JMSPooledConnAvail	Monitors the number of sessions available, unavailable, and reserved in a JMS Pooled Connection.
JMSPooledConnError	Monitors the sessions leaked and sessions unable to be refreshed in a JMS Pooled Connection.
JMSPooledConnSession	Monitors statistics on the sessions in a JMS Pooled Connection. This script reports on the number of allocated and destroyed sessions, the current and maximum capacity of the pool, and the average number of reserved sessions.
JMSPooledConnWait	Monitors the number of threads waiting on the sessions in a JMS Pooled Connection, and the amount of time the threads wait.

77.1.6 Java Transaction API (JTA) Knowledge Scripts

Run the following Knowledge Scripts on the JTA subsystem of a WebLogic Server:

Knowledge Script	What It Does
JTAActiveTrans	Monitors the current number of transactions in progress on a WebLogic Server.
JTACompletedTrans	Monitors the transactions that have completed on a WebLogic Server since the last sample.
JTAHealthState	Returns the health state of the JTA subsystem of a WebLogic Server.
JTATransRolledBack	Provides statistics on the causes for transaction rollbacks.
TransResources	Returns statistics for the transactional resources of a WebLogic Server.
TransResHealthState	Returns the health state of the transactional resources of a WebLogic Server.
TransResHeuristics	Provides a breakdown of the reasons for heuristic completes for the transactional resources of a WebLogic Server.
TransCateg	Returns statistics for the transaction categories of a WebLogic Server.
TransCategRollBacks	Provides statistics on the reasons why transactions were rolled back for the transaction categories of a WebLogic Server.

77.1.7 Enterprise JavaBeans (EJB) Knowledge Scripts

Run the following Knowledge Scripts on the EJBs on a WebLogic Server:

Knowledge Script	What It Does
EntityEJBCache	Returns statistics on caching for an Entity EJB.
EntityEJBError	Returns statistics on errors generated by an Entity EJB.
EntityEJBPool	Returns the percentage of beans that are idle and in-use for an Entity EJB.
EntityEJBTrans	Returns statistics on transactions for an Entity EJB.
EntityEJBWait	Returns the number of times a client has waited for an Entity EJB and the number of times that clients have timed out waiting for an Entity EJB.
MsgDrivenEJBError	Monitors errors generated by a message-driven EJB.
MsgDrivenEJBPool	Monitors the number of message-driven EJBs that are in use and the number that are idle.
MsgDrivenEJBTrans	Returns statistics on transactions for a message-driven EJB.
MsgDrivenEJBWait	Returns the number of times a client has waited for a message-driven EJB and the number of times that clients have timed out waiting for a message-driven EJB.
StatefulEJBCache	Returns statistics on the cache for a Stateful EJB.
StatefulEJBTrans	Returns statistics on transactions for a Stateful EJB.
StatefulEJBWait	Returns the number of times a client waited for a bean and the number of times that clients have timed out waiting for a bean for the Stateful EJB.

Knowledge Script	What It Does
StatelessEJBError	Monitors errors generated by a Stateless EJB.
StatelessEJBPool	Returns the number and percentage of beans that are idle and in use for a Stateless EJB.
StatelessEJBTrans	Returns statistics on transactions for a Stateless EJB.
StatefulEJBWait	Returns the number of times a client waited for a bean and the number of times that clients have timed out waiting for a bean for the Stateless EJB.

77.1.8 Web Applications and Servlets Knowledge Scripts

Run the following Knowledge Scripts on the Web applications and servlets on a WebLogic Server:

Knowledge Script	What It Does
ServletExecTime	Monitors the execution times and number of times that the servlets of a Web application were invoked.
WebAppSessions	Monitors the current number of sessions of a Web application and the number of sessions that have been run since the last sample.

77.1.9 Connector Connections Knowledge Scripts

Run the following Knowledge Scripts on the Connector connections of a WebLogic Server:

Knowledge Script	What It Does
ConnectorConnCurrent	Monitors statistics on the current number of active and free Connector connections.
ConnectorConnRequests	Returns the number of Connector connections created, destroyed, matched, rejected and recycled since the last sample.

77.1.10 Data-Gathering Knowledge Script

Run the following Knowledge Script to start or stop components that gather data for the Knowledge Scripts:

Knowledge Script	What It Does
NetIQAgent	Starts or stops the NetIQ UNIX agent that helps gather data about WebLogic Servers and their components.

77.1.11 SQL Profiling and Monitoring Knowledge Scripts

Run the following Knowledge Script to monitor individual SQL statements:

Knowledge Script	What It Does
JDBCEnableSQLProfiling	Enables or disables profiling of SQL statements.
JDBCSQLMonitoring	Monitors the SQL statements executed within a JDBC Connection Pool.
JDBCSQLMonitoringTopN	Monitors the SQL statements executed within a JDBC Connection Pool that take the longest amount of time.

77.1.12 WebLogic Server Report Knowledge Scripts

Run the following Knowledge Scripts to generate reports:

Knowledge Script	What It Does
Report_HealthSummary	Generates a report summarizing the health of monitored WebLogic servers.
Report_PerfSummary	Generates a report summarizing the performance of monitored WebLogic servers.

77.2 Availability

Use this Knowledge Script to monitor availability of a WebLogic Server. This script verifies that a WebLogic Server is running and can accept requests.

77.2.1 Versions of WebLogic Supported

8.1 SP6, 9.0, 9.1, 9.2, and 10.x

77.2.2 Resource Object

WebLogic Server

77.2.3 Default Schedule

The default interval for this Knowledge Script is Every 15 minutes.

77.2.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default value is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default value is n.
Event severity when WebLogic Server is not responding?	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 10.

77.3 ClusterMessage

Use this Knowledge Script to monitor a server's view of the members of a WebLogic cluster. This script reports statistics on the multicast message and fragments sent and received by a WebLogic server.

77.3.1 Versions of WebLogic Supported

8.1 SP6, 9.0, 9.1, 9.2, and 10.x

77.3.2 Resource Object

WebLogic Server

77.3.3 Default Schedule

The default interval for this Knowledge Script is Every 15 minutes.

77.3.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default value is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default value is n.
Fragments sent threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of fragments sent since the last sample exceeds this threshold, this Knowledge Script raises an event. The default value is –1.
Event severity when fragments sent exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Fragments received threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of fragments received since the last sample exceeds this threshold, this Knowledge Script raises an event. The default value is –1.
Event severity when fragments received exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Resend requests threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of requests to resend a message since the last sample exceeds this threshold, this Knowledge Script raises an event. The default value is –1.
Event severity when resend requests exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.

Description	How to Set It
Messages lost threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of incoming messages lost since the last sample exceeds this threshold, this Knowledge Script raises an event. The default value is -1.
Event severity when messages lost exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Foreign fragments dropped threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of fragments received from a foreign domain or foreign cluster since the last sample exceeds this threshold, this Knowledge Script raises an event. The default value is 0.
Event severity when foreign fragments dropped exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.

77.4 ConnectorConnCurrent

Use this Knowledge Script to monitor the number of active and free connections in a Connector Connection Pool. These statistics provide a view of the Connector Connection Pool from the server's perspective, which will help determine if the capacity of the pool is large enough.

77.4.1 Versions of WebLogic Supported

8.1 SP6, 9.0, 9.1, 9.2, and 10.x

77.4.2 Resource Object

WebLogic Server

77.4.3 Default Schedule

The default interval for this Knowledge Script is Every 15 minutes.

77.4.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default value is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default value is n.
Active connections threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the current number of active connections exceeds this threshold, this Knowledge Script raises an event. The default value is –1.
Event severity when active connections exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Peak active connections threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the peak number of active connections exceeds this threshold, this Knowledge Script raises an event. The default value is –1.
Event severity when peak active connections exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Average active connections threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the average number of active connections exceeds this threshold, this Knowledge Script raises an event. The default value is –1.
Event severity when average active connections exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.

Description	How to Set It
Free connections threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the current number of free connections exceeds this threshold, this Knowledge Script raises an event. The default value is –1.
Event severity when free connections exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Peak free connections threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the peak number of free connections exceeds this threshold, this Knowledge Script raises an event. The default value is –1.
Event severity when peak free connections exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Percent of connections in use threshold	Specify a threshold value using an integer greater than or equal to –1 and less than or equal to 100. Use –1 to ignore this threshold. If the percent of connections in use exceeds this threshold, this Knowledge Script raises an event. The default value is –1.
Event severity when percent of connections in use exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.

77.5 ConnectorConnRequests

Use this Knowledge Script to monitor the rate at which a Connector Connection Pool is servicing requests for connections. These statistics provide a view of the Connector Connection Pool from the clients' perspective, which can help determine if the capacity of the pool is large enough.

77.5.1 Versions of WebLogic Supported

8.1 SP6, 9.0, 9.1, 9.2, and 10.x

77.5.2 Resource Object

WebLogic Server

77.5.3 Default Schedule

The default interval for this Knowledge Script is Every 15 minutes.

77.5.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default value is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default value is n.
Connections created threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of connections created since the last sample exceeds this threshold, this Knowledge Script raises an event. The default value is –1.
Event severity when connections created exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Connections destroyed threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of connections destroyed since the last sample exceeds this threshold, this Knowledge Script raises an event. The default value is –1.
Event severity when connections destroyed exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Connections matched threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of times since the last sample that a request for a connection was satisfied via an existing connection exceeds this threshold, this Knowledge Script raises an event. The default value is 0.
Event severity when connections matched exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.

Description	How to Set It
Connections rejected threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of times since the last sample that a request for a connection was rejected exceeds this threshold, this Knowledge Script raises an event. The default value is –1.
Event severity when connections rejected exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Connections recycled threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of connections that have been recycled since the last sample exceeds this threshold, this Knowledge Script raises an event. The default value is –1.
Event severity when connections recycled exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Connections leaked threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of leaked connections since the last sample exceeds this threshold, this Knowledge Script raises an event. The default value is 0.
Event severity when leaked connections exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.

77.6 EntityEJBCache

Use this Knowledge Script to monitor statistics for an Entity EJB. This script reports caching statistics for an Entity EJB.

This script may be used to determine a cache hit ratio and how frequently instances of the Entity EJB are being activated and passivated. These values will help determine if the size of the cache is appropriate.

77.6.1 Versions of WebLogic Supported

8.1 SP6, 9.0, 9.1, 9.2, and 10.x

77.6.2 Resource Object

WebLogic Server

77.6.3 Default Schedule

The default interval for this Knowledge Script is Every 15 minutes.

77.6.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default value is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default value is n.
Current beans threshold	Specify a threshold value using an integer value greater than or equal to –1. Use –1 to ignore this threshold. If the number of beans currently in use exceeds this threshold, this Knowledge Script raises an event. The default value is –1.
Event severity when current beans exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Cache accesses threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of cache accesses since the last sample exceeds this threshold, this Knowledge Script raises an event. The default value is –1.
Event severity when cache accesses exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Cache hit ratio threshold	Specify a threshold value using a real number greater than or equal to –1. Use –1 to ignore this threshold. If the cache hit ratio (expressed as a percentage) since the last sample falls below this threshold, this Knowledge Script raises an event. The default value is –1.
Event severity when cache hit ratio falls below threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.

Description	How to Set It
Activations threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of activations since the last sample exceeds this threshold, this Knowledge Script raises an event. The default value is –1.
Event severity when activations exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Passivations threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of passivations since the last sample exceeds this threshold, this Knowledge Script raises an event. The default value is –1.
Event severity when passivations exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Cache miss count threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the cache miss count since the last sample exceeds this threshold, this Knowledge Script raises an event. The default value is –1.
Event severity when cache miss count exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.

77.7 EntityEJBError

Use this Knowledge Script to monitor errors generated by an Entity EJB. This script reports error statistics for an Entity EJB.

This script may be used to determine the number of times the Entity EJB was destroyed due to an exception, and the number of failed attempts to retrieve an EJB from the pool. These values will help monitor the Entity EJB if errors occur.

77.7.1 Versions of WebLogic Supported

8.1 SP6, 9.0, 9.1, 9.2, and 10.x

77.7.2 Resource Object

WebLogic Server

77.7.3 Default Schedule

The default interval for this Knowledge Script is Every 15 minutes.

77.7.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default value is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default value is n.
Destroyed bean instances threshold	Specify a threshold value using an integer value greater than or equal to –1. Use –1 to ignore this threshold. If the number of times since the last sample that a bean instance was destroyed due to a thrown exception exceeds this threshold, this Knowledge Script raises an event. The default value is 0.
Event severity when destroyed bean instances exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Miss count threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of failed attempts to retrieve a bean from the free pool since the last sample exceeds this threshold, this Knowledge Script raises an event. The default value is 0.
Event severity when miss count exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.

77.8 EntityEJBPool

Use this Knowledge Script to monitor for the number or percentage of in-use and idle beans in an Entity EJB pool. These values will help determine if the size of the pool has been set properly.

77.8.1 Versions of WebLogic Supported

8.1 SP6, 9.0, 9.1, 9.2, and 10.x

77.8.2 Resource Object

WebLogic Server

77.8.3 Default Schedule

The default interval for this Knowledge Script is Every 15 minutes.

77.8.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default value is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default value is n.
Beans idle threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of beans that are allocated but idle exceeds this threshold, this Knowledge Script raises an event. The default value is –1.
Event severity when beans idle exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Beans in use threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of beans in use exceeds this threshold, this Knowledge Script raises an event. The default value is –1.
Event severity when beans in use exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Percent of pool in use threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the percentage of available beans in the pool that are in use exceeds this threshold, this Knowledge Script raises an event. The default value is –1.
Event severity when percent of pool in use exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.

77.9 EntityEJBTrans

Use this Knowledge Script to monitor the transaction rates for an Entity EJB. Transactions are rolled back when timeouts or application, system or resource errors occur. The JTATransRolledBack Knowledge Script provides a breakdown of the reasons for rollbacks.

77.9.1 Versions of WebLogic Supported

8.1 SP6, 9.0, 9.1, 9.2, and 10.x

77.9.2 Resource Object

WebLogic Server

77.9.3 Default Schedule

The default interval for this Knowledge Script is Every 15 minutes.

77.9.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default value is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default value is n.
Transactions committed threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of transactions committed since the last sample exceeds this threshold, this Knowledge Script raises an event. The default value is –1.
Event severity when transactions committed exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Transactions rolled back threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of transactions rolled back since the last sample exceeds this threshold, this Knowledge Script raises an event. The default value is 0.
Event severity when transactions rolled back exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Transactions timed out threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of transactions timed out since the last sample exceeds this threshold, this Knowledge Script raises an event. The default value is 0.
Event severity when transactions timed out exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.

77.10 EntityEJBWait

Use this Knowledge Script to monitor the number of times a request had to wait for an EJB and the number of times a request timed out waiting for an EJB. Increasing the cache size may help reduce the number of timeouts.

77.10.1 Versions of WebLogic Supported

8.1 SP6, 9.0, 9.1, 9.2, and 10.x

77.10.2 Resource Object

WebLogic Server

77.10.3 Default Schedule

The default interval for this Knowledge Script is Every 15 minutes.

77.10.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default value is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default value is n.
Times waited threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of times since the last sample that clients have waited for a bean exceeds this threshold, this Knowledge Script raises an event. The default value is –1.
Event severity when times waited exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Timeouts threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of timeouts since the last sample exceeds this threshold, this Knowledge Script raises an event. The default value is 0.
Event severity when timeouts exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.

77.11 HealthCheck

Use this Knowledge Script to make sure a WebLogic Server is running and is able to service requests. This script performs the following checks:

- Verifies the WebLogic Server is running.
- Verifies the WebLogic Server is able to respond to a request.
- Verifies the WebLogic Server is able to accept connections from clients.

This script may also be used to:

- Restart the WebLogic Server if the script determines it is not running.
- Set response time thresholds for responding to requests and establishing connections.
- Raise events (with user-defined severity levels) if the WebLogic Server is not running, is unable to respond to a request, or is unable to accept connections.

If this script detects that the WebLogic Server is not running, it raises a general event to alert you to the condition but it does not perform additional tests for responding to a request and accepting a connection from a client. Therefore, if the WebLogic Server is not running, the script does not return data or compare the thresholds for the **WebLogic Ping time** and the **Average connection time**, and does not raise events to indicate that a WebLogic Ping or connectivity test failed.

If a WebLogic Server is running but is not able to respond to a request, this Knowledge Script raises an event to indicate the ping request failed, but the script does not return data or compare the thresholds for the **WebLogic Ping time**. Similarly, if a WebLogic Server is running, but is not able to accept a connection from a client, this Knowledge Script raises an event to indicate that the connectivity test failed, but the script does not return data or compare the thresholds for the **Average connection time**.

77.11.1 Versions of WebLogic Supported

8.1 SP6, 9.0, 9.1, 9.2, and 10.x

77.11.2 Resource Object

WebLogic Server

77.11.3 Default Schedule

The default interval for this Knowledge Script is Run once.

77.11.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default value is y.

Description	How to Set It
Collect data?	Set to **y** to collect data for reports and graphs. The default value is n.
Event severity when server is not running	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 10.
Restart WebLogic Server if not running?	Set to **y** to restart the WebLogic server if it is not running. The default value is n.
Use Node Manager to restart server?	Set to **y** to restart the WebLogic server using Node Manager. The default value is n.
Start Command	Set to the name of the script file that you use to start a WebLogic Server, including any parameters that the script requires. The name of the script must include the complete path for the file.
Start Command Parameters	Specify conditions to apply to the Start Command parameter.
Pass name of server, IP address, port, admin username and password to Start Script?	Set to **y** to pass these parameters to the Start Script. These parameters will be added to the end of the string supplied for Start Script. The default value is n.
Start time limit	Set to the number of seconds within which the WebLogic Server should complete initialization. The default value is 300.
Requests	Set to the number of requests, between 1 and 10, that should be made to the server to determine if it is able to respond to requests. The default value is 3.
WebLogic Ping time threshold in secs	Specify a threshold value using a real number greater than or equal to –1. Use –1 to ignore this threshold. If the WebLogic Ping time in seconds exceeds this threshold, this Knowledge Script raises an event. The default value is 0.
Event severity when WebLogic Ping response not received	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 10.
Event severity when WebLogic Ping time exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Connections	Set to the number of connections, between 1 and 10, that should be made to the server to determine if it is able to accept connections from clients. The default value is 3.
Average connection time threshold in secs	Specify a threshold value using a real number greater than or equal to –1. Use –1 to ignore this threshold. If the average time in seconds it took the server to establish a connection exceeds this threshold, this Knowledge Script raises an event. The default value is 0.
Event severity when connection not established	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 10.
Event severity when connection time exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.

77.12 JDBCAvailableConnections

Use this Knowledge Script to monitor the available number of connections in a JDBC Connection Pool. This script reports the number of available and unavailable connections for a JDBC Connection Pool.

This script may be used to monitor the number available and unavailable connections in a JDBC Connection Pool, and the peak number of available and unavailable connections in a JDBC Connection Pool. These values will help determine if the JDBC Connection Pool is over-utilized or under-utilized.

77.12.1 Versions of WebLogic Supported

8.1 SP6, 9.0, 9.1, 9.2, and 10.x

77.12.2 Resource Object

WebLogic Server

77.12.3 Default Schedule

The default interval for this Knowledge Script is Every 15 minutes.

77.12.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default value is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default value is n.
Available connections threshold	Specify a threshold value using an integer value greater than or equal to –1. Use –1 to ignore this threshold. If the number of available connections exceeds this threshold, this Knowledge Script raises an event. The default value is –1.
Event severity when available connections exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Peak number of available connections threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the peak number of available connections exceeds this threshold, this Knowledge Script raises an event. The default value is –1.
Event severity when peak number of available connections exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Unavailable connections threshold	Specify a threshold value using an integer value greater than or equal to –1. Use –1 to ignore this threshold. If the number of unavailable connections exceeds this threshold, this Knowledge Script raises an event. The default value is –1.

Description	How to Set It
Event severity when unavailable connections exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Peak number of unavailable connections threshold	Specify a threshold value using an integer greater than or equal to −1. Use −1 to ignore this threshold. If the peak number of unavailable connections exceeds this threshold, this Knowledge Script raises an event. The default value is −1.
Event severity when peak number of unavailable connections exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.

77.13 JDBCClients

Use this Knowledge Script to monitor the number of requests that had to wait for a JDBC Connection and how long it took for a request to get a connection. If these values are consistently high, consider increasing the size of the pool.

This script may be used to measure how quickly and efficiently the JDBC Connection Pool is servicing clients' requests and will help determine if the capacity of the pool is sufficient.

77.13.1 Versions of WebLogic Supported

8.1 SP6, 9.0, 9.1, 9.2, and 10.x

77.13.2 Resource Object

WebLogic Server

77.13.3 Default Schedule

The default interval for this Knowledge Script is Every 15 minutes.

77.13.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default value is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default value is n.
Clients waiting threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of clients waiting for a JDBC connection exceeds this threshold, this Knowledge Script raises an event. The default value is –1.
Event severity when clients waiting exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Peak clients waiting threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the peak number of clients waiting for a JDBC connection exceeds this threshold, this Knowledge Script raises an event. The default value is 0.
Event severity when peak clients waiting exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Peak wait time threshold in secs	Specify a threshold value using a real number greater than or equal to –1. Use –1 to ignore this threshold. If the longest time (in seconds) that a client waited for a JDBC connection exceeds this threshold, this Knowledge Script raises an event. The default value is –1.

Description	How to Set It
Event severity when peak wait time exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Average connection delay time threshold in secs	Specify a threshold value using a real number greater than or equal to –1. Use –1 to ignore this threshold. If the average time (in seconds) that a client waited for a JDBC connection exceeds this threshold, this Knowledge Script raises an event. The default value is –1.
Event severity when average connection delay time exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.

77.14 JDBCConnections

Use this Knowledge Script to monitor a JDBC Connection Pool. This script reports the number of active connections in the JDBC Connection Pool and will indicate whether the capacity of the pool needs adjustment.

77.14.1 Versions of WebLogic Supported

8.1 SP6, 9.0, 9.1, 9.2, and 10.x

77.14.2 Resource Object

WebLogic Server

77.14.3 Default Schedule

The default interval for this Knowledge Script is Run once.

77.14.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default value is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default value is n.
Active connections threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of active connections exceeds this threshold, this Knowledge Script raises an event. The default value is –1.
Event severity when active connections exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Total connections threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the total number of connections exceeds this threshold, this Knowledge Script raises an event. The default value is –1.
Event severity when total connections exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Peak active connections threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the peak number of active connections exceeds this threshold, this Knowledge Script raises an event. The default value is –1.
Event severity when peak active connections exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.

Description	How to Set It
Percent of connections in use threshold	Specify a threshold value using an integer greater than or equal to –1 and less than or equal to 100. Use –1 to ignore this threshold. If the percent of connections in use exceeds this threshold, this Knowledge Script raises an event. The default value is -1.
Event severity when percent of connections in use exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Leaked connections threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of leaked connections since the last sample exceeds this threshold, this Knowledge Script raises an event. The default value is 0.
Event severity when leaked connections exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Refresh failures threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of refresh failures since the last sample exceeds this threshold, this Knowledge Script raises an event. The default value is 0.
Event severity when refresh failures exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Average active connections threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the average number of active connections exceeds this threshold, this Knowledge Script raises an event. The default value is –1.
Event severity when average active connections exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.

77.15 JDBCConnectionCapacity

Use this Knowledge Script to monitor the current and maximum capacity of a JDBC Connection Pool. These values will help determine if the JDBC Connection Pool is too large or too small.

77.15.1 Versions of WebLogic Supported

8.1 SP6, 9.0, 9.1, 9.2, and 10.x

77.15.2 Resource Object

WebLogic Server

77.15.3 Default Schedule

The default interval for this Knowledge Script is Every 15 minutes.

77.15.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default value is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default value is n.
Current capacity threshold	Specify a threshold value using an integer value greater than or equal to –1. Use –1 to ignore this threshold. If the current capacity exceeds this threshold, this Knowledge Script raises an event. The default value is –1.
Event severity when current capacity exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Maximum capacity threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the maximum capacity exceeds this threshold, this Knowledge Script raises an event. The default value is –1.
Event severity when maximum capacity exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.

77.16 JDBCEnableSQLProfiling

Use this Knowledge Script to enable or disable profiling of SQL statements. This script provides a way to enable or disable SQL statement profiling without using the Administrator Console.

77.16.1 Versions of WebLogic Supported

8.1 SP6, 9.0, 9.1, 9.2, and 10.x

77.16.2 Resource Object

WebLogic Server

77.16.3 Default Schedule

The default interval for this Knowledge Script is Run once.

77.16.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default value is y.
Enable SQL statement profiling	Set to **y** to enable SQL statement profiling within the WebLogic Server. The default value is y.

77.17 JDBCSQLMonitoring

Use this Knowledge Script to monitor the SQL statements executed within a JDBC Connection Pool. These values will help determine if the JDBC Connection Pool is configured properly or has a slow response time, or if the database the pool connects to has a slow response time.

77.17.1 Version of WebLogic Supported

8.1 SP6

77.17.2 Resource Object

WebLogic Server

77.17.3 Default Schedule

The default interval for this Knowledge Script is Every 15 minutes.

77.17.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default value is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default value is n.
SQL statement filter	Set to a string that specifies the SQL statement filter. The SQL statement filter matches substrings of the SQL statement text. The default value is .*.
Number of statements executed threshold	Specify a threshold value using an integer value greater than or equal to –1. Use –1 to ignore this threshold. If the number of SQL statements executed since the last sample exceeds this threshold, an event is raised. The default value is –1.
Event severity when number of statements executed exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Average statement execution time threshold in secs	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the average statement execution time in seconds since the last sample exceeds this threshold, an event is raised. The default value is –1.
Event severity when average statement execution time exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Minimum statement execution time threshold in secs	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the minimum statement execution time in seconds since the last sample exceeds this threshold, an event is raised. The default value is –1.

Description	How to Set It
Event severity when minimum statement execution time exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Maximum statement execution time threshold in secs	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the maximum statement execution time in seconds since the last sample exceeds this threshold, an event is raised. The default value is –1.
Event severity when maximum statement execution time exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.

77.18 JDBCSQLMonitoringTopN

Use this Knowledge Script to monitor the SQL statements executed within a JDBC Connection Pool that take the longest amount of time. These values will help determine which calls to the database are most adversely affecting performance.

77.18.1 Version of WebLogic Supported

8.1 SP6

77.18.2 Resource Object

WebLogic Server

77.18.3 Default Schedule

The default interval for this Knowledge Script is Every 15 minutes.

77.18.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default value is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default value is n.
SQL statement filter	Set to a string that specifies the SQL statement filter. The SQL statement filter matches substrings of the SQL statement text.
Number of statements	Specify the number of statements, between 1 and 5, for which data should be collected. The default value is 5.
Execution time threshold in secs	Specify a threshold value using an integer value greater than or equal to –1. Use –1 to ignore this threshold. If the execution time of a SQL statement in seconds exceeds this threshold, an event is raised. The default value is –1.
Event severity when execution time exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.

77.19 JMS

Use this Knowledge Script to monitor the Java Message System (JMS). This script monitors the number of JMS Connections in use and the number of JMS servers deployed by a WebLogic Server.

77.19.1 Versions of WebLogic Supported

8.1 SP6, 9.0, 9.1, 9.2, and 10.x

77.19.2 Resource Object

WebLogic Server

77.19.3 Default Schedule

The default interval for this Knowledge Script is Every 15 minutes.

77.19.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default value is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default value is n.
Current connections threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the current number of JMS Connections exceeds this threshold, this Knowledge Script raises an event. The default value is –1.
Event severity when current connections exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Peak connections threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the peak number of JMS Connections exceeds this threshold, this Knowledge Script raises an event. The default value is –1.
Event severity when peak connections exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Connections made threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of JMS Connections made to this WebLogic Server since the last sample exceeds this threshold, this Knowledge Script raises an event. The default value is –1.
Event severity when connections made exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.

Description	How to Set It
Current servers threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the current number of deployed JMS Servers exceeds this threshold, this Knowledge Script raises an event. The default value is –1.
Event severity when current servers exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Peak servers threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the peak number of deployed JMS Servers exceeds this threshold, this Knowledge Script raises an event. The default value is –1.
Event severity when peak servers exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Servers deployed threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of JMS Servers deployed since the last sample exceeds this threshold, this Knowledge Script raises an event. The default value is –1.
Event severity when servers deployed exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.

77.20 JMSConnectionsSessions

Use this Knowledge Script to monitor JMS connections. This script monitors the number of sessions in use for each JMS Connection and the rate at which sessions are being opened.

77.20.1 Versions of WebLogic Supported

8.1 SP6, 9.0, 9.1, 9.2, and 10.x

77.20.2 Resource Object

WebLogic Server

77.20.3 Default Schedule

The default interval for this Knowledge Script is Every 15 minutes.

77.20.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default value is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default value is n.
Current sessions threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the current number of sessions for the JMS Connection exceeds this threshold, this Knowledge Script raises an event. The default value is –1.
Event severity when current sessions exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Peak sessions threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the peak number of sessions for the JMS Connection exceeds this threshold, this Knowledge Script raises an event. The default value is –1.
Event severity when peak sessions exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Sessions opened threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of sessions opened for the JMS Connection since the last sample exceeds this threshold, this Knowledge Script raises an event. The default value is –1.
Event severity when sessions opened exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.

77.21 JMSHealthState

Use this Knowledge Script to monitor the health state of the JMS subsystem of a WebLogic Server.

77.21.1 Versions of WebLogic Supported

8.1 SP6, 9.0, 9.1, 9.2, and 10.x

77.21.2 Resource Object

WebLogic Server

77.21.3 Default Schedule

The default interval for this Knowledge Script is Every 15 minutes.

77.21.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Collect data?	Set to **y** to collect data for reports and graphs. The default value is n.
Scale to 100?	Set to **y** to scale the values to 100. The default values range from 0-3, where 0 is `OK`, and 3 is `FAIL`. Setting to y will scale the values from 0-100, where 0 is `FAIL` and 100 is `OK`. The default value is n.
Event for health state of FAIL?	Set to **y** to raise an event if the health state is `FAIL`. The default value is y.
Event severity when health state is FAIL?	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 5.
Event for health state of CRITICAL?	Set to **y** to raise an event if the health state is `CRITICAL`. The default value is y.
Event severity when health state is CRITICAL	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 15.
Event for health state of WARNING?	Set to **y** to raise an event if the health state is `WARNING`. The default value is y.
Event severity when health state is WARNING	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Event for health state of OK?	Set to **y** to raise an event if the health state is `OK`. The default value is n.
Event severity when health state is OK	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 35.

77.22 JMSPooledConnAvail

Use this Knowledge Script to monitor number of sessions available, unavailable, and reserved in a JMS Pooled Connection. These values will help determine if the JMS Pooled Connection is too large or too small.

77.22.1 Versions of WebLogic Supported

8.1 SP6, 9.0, 9.1, 9.2, and 10.x

77.22.2 Resource Object

WebLogic Server

77.22.3 Default Schedule

The default interval for this Knowledge Script is Every 15 minutes.

77.22.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default value is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default value is n.
Available sessions threshold	Specify a threshold value using an integer value greater than or equal to –1. Use –1 to ignore this threshold. If the number of available sessions exceeds this threshold, an event is raised. The default value is –1.
Event severity when available sessions exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Peak available sessions threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the peak number of available sessions exceeds this threshold, an event is raised. The default value is –1.
Event severity when peak available sessions exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Reserved sessions threshold	Specify a threshold value using an integer value greater than or equal to –1. Use –1 to ignore this threshold. If the number of reserved sessions exceeds this threshold, an event is raised. The default value is –1.
Event severity when reserved sessions exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Peak reserved sessions threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the peak number of reserved sessions exceeds this threshold, an event is raised. The default value is –1.

Description	How to Set It
Event severity when peak reserved sessions exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Unavailable sessions threshold	Specify a threshold value using an integer value greater than or equal to −1. Use −1 to ignore this threshold. If the number of unavailable sessions exceeds this threshold, an event is raised. The default value is −1.
Event severity when unavailable sessions exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Peak number of unavailable sessions threshold	Specify a threshold value using an integer greater than or equal to −1. Use −1 to ignore this threshold. If the peak number of unavailable sessions exceeds this threshold, an event is raised. The default value is −1.
Event severity when peak number of unavailable sessions exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.

77.23 JMSPooledConnError

Use this Knowledge Script to monitor the sessions leaked and sessions unable to be refreshed in a JMS Pooled Connection. These values will help determine when errors and leaks occur when using a JMS Pooled Connection.

77.23.1 Versions of WebLogic Supported

8.1 SP6, 9.0, 9.1, 9.2, and 10.x

77.23.2 Resource Object

WebLogic Server

77.23.3 Default Schedule

The default interval for this Knowledge Script is Every 15 minutes.

77.23.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default value is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default value is n.
Leaked sessions threshold	Specify a threshold value using an integer value greater than or equal to –1. Use –1 to ignore this threshold. If the number of leaked sessions since the last sample exceeds this threshold, an event is raised. The default value is 0.
Event severity when leaked sessions exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Refresh failures threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of refresh failures since the last sample exceeds this threshold, an event is raised. The default value is 0.
Event severity when refresh failures exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.

77.24 JMSPooledConnSession

Use this Knowledge Script to monitor statistics on the sessions in a JMS Pooled Connection. This script reports on the number of allocated and destroyed sessions, the current and maximum capacity of the pool, and the average number of reserved sessions. These values will help determine if the JMS Pooled Connection is overloaded or under-utilized.

77.24.1 Versions of WebLogic Supported

8.1 SP6, 9.0, 9.1, 9.2, and 10.x

77.24.2 Resource Object

WebLogic Server

77.24.3 Default Schedule

The default interval for this Knowledge Script is Every 15 minutes.

77.24.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default value is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default value is n.
Current capacity threshold	Specify a threshold value using an integer value greater than or equal to –1. Use –1 to ignore this threshold. If the number of current capacity exceeds this threshold, an event is raised. The default value is –1.
Event severity when current capacity exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Maximum capacity threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the maximum capacity of available sessions exceeds this threshold, an event is raised. The default value is –1.
Event severity when maximum capacity exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Allocated sessions threshold	Specify a threshold value using an integer value greater than or equal to –1. Use –1 to ignore this threshold. If the number of allocated sessions since the last sample exceeds this threshold, an event is raised. The default value is –1.
Event severity when allocated sessions exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.

Description	How to Set It
Destroyed sessions threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of destroyed sessions since the last sample exceeds this threshold, an event is raised. The default value is –1.
Event severity when destroyed sessions exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Average number of reserved sessions threshold	Specify a threshold value using an integer value greater than or equal to –1. Use –1 to ignore this threshold. If the average number of reserved sessions exceeds this threshold, an event is raised. The default value is –1.
Event severity when average number of reserved sessions exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.

77.25 JMSPooledConnWait

Use this Knowledge Script to monitor the number of threads waiting on the sessions in a JMS Pooled Connection, and the amount of time the threads wait. These values will help determine if the JMS Pooled Connection is overloaded.

77.25.1 Versions of WebLogic Supported

8.1 SP6, 9.0, 9.1, 9.2, and 10.x

77.25.2 Resource Object

WebLogic Server

77.25.3 Default Schedule

The default interval for this Knowledge Script is Every 15 minutes.

77.25.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default value is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default value is n.
Threads waiting threshold	Specify a threshold value using an integer value greater than or equal to –1. Use –1 to ignore this threshold. If the number of threads waiting for a session exceeds this threshold, an event is raised. The default value is –1.
Event severity when threads waiting exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Peak number of threads waiting threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the peak number of threads waiting for a session exceeds this threshold, an event is raised. The default value is –1.
Event severity when peak number of threads waiting exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Peak wait time threshold in secs	Specify a threshold value using an integer value greater than or equal to –1. Use –1 to ignore this threshold. If the longest amount of time a thread waited for a session in seconds since the last sample exceeds this threshold, an event is raised. The default value is –1.
Event severity when peak wait time exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.

Description	How to Set It
Average creation delay time threshold in secs	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the average amount of time to create each session in seconds exceeds this threshold, an event is raised. The default value is –1.
Event severity when average creation delay time exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.

77.26 JMSServersBytesStored

Use this Knowledge Script to monitor JMS servers. This script monitors the number of bytes consumed by messages on each JMS server.

The **Time in threshold condition** parameter is the time (in seconds) that the current number of bytes consumed exceeds a WebLogic Server threshold for that JMS server. This value, along with the current number of bytes, can help you adjust the maximum bytes for the JMS server.

77.26.1 Versions of WebLogic Supported

8.1 SP6, 9.0, 9.1, 9.2, and 10.x

77.26.2 Resource Object

WebLogic Server

77.26.3 Default Schedule

The default interval for this Knowledge Script is Every 15 minutes.

77.26.4 Setting Parameter values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default value is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default value is n.
Current bytes threshold	Specify a threshold value using a real number greater than or equal to –1. Use –1 to ignore this threshold. If the current number of bytes stored on this JMS Server exceeds this threshold, this Knowledge Script raises an event. The default value is –1.
Event severity when current bytes exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Pending bytes threshold	Specify a threshold value using a real number greater than or equal to –1. Use –1 to ignore this threshold. If the current number of pending bytes stored on this JMS server exceeds this threshold, this Knowledge Script raises an event. The default value is –1.
Event severity when pending bytes exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Peak bytes threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the peak number of bytes stored on this JMS Server exceeds this threshold, this Knowledge Script raises an event. The default value is –1.

Description	How to Set It
Event severity when peak bytes exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Time in threshold condition threshold in secs	Specify a threshold value using a real number greater than or equal to –1. Use –1 to ignore this threshold. If the number of seconds spent in the threshold condition (due to the number of bytes stored on this JMS Server) since the last sample exceeds this threshold, this Knowledge Script raises an event. The default value is 0.
Event severity when time in threshold condition exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.

77.27 JMSServersDestinations

Use this Knowledge Script to monitor JMS servers. This script monitors the current number of destinations for each JMS server and the rate at which those destinations are being created.

77.27.1 Versions of WebLogic Supported

8.1 SP6, 9.0, 9.1, 9.2, and 10.x

77.27.2 Resource Object

WebLogic Server

77.27.3 Default Schedule

The default interval for this Knowledge Script is Every 15 minutes.

77.27.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default value is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default value is n.
Current destinations threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the current number of destinations for this JMS server exceeds this threshold, this Knowledge Script raises an event. The default value is –1.
Event severity when current destinations exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Peak destinations threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the peak number of destinations for this JMS server exceeds this threshold, this Knowledge Script raises an event. The default value is –1.
Event severity when peak destinations exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Destinations instantiated threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of destinations instantiated on this JMS server since the last sample exceeds this threshold, this Knowledge Script raises an event. The default value is –1.
Event severity when destinations instantiated exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.

77.28 JMSServersHealthState

Use this Knowledge Script to monitor the health state of the JMS servers of a WebLogic Server.

77.28.1 Versions of WebLogic Supported

8.1 SP6, 9.0, 9.1, 9.2, and 10.x

77.28.2 Resource Object

WebLogic Server

77.28.3 Default Schedule

The default interval for this Knowledge Script is Every 15 minutes.

77.28.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Collect data?	Set to **y** to collect data for reports and graphs. The default value is n.
Scale to 100?	Set to y to scale the values to 100. The default values range from 0-3, where 0 is `OK`, and 3 is `FAIL`. Setting to y will scale the values from 0-100, where 0 is `FAIL` and 100 is `OK`. The default value is n.
Event for health state of FAIL?	Set to **y** to raise an event if the health state is `FAIL`. The default value is y.
Event severity when health state is FAIL?	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 5.
Event for health state of CRITICAL?	Set to **y** to raise an event if the health state is `CRITICAL`. The default value is y.
Event severity when health state is CRITICAL	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 15.
Event for health state of WARNING?	Set to **y** to raise an event if the health state is `WARNING`. The default value is y.
Event severity when health state is WARNING	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Event for health state of OK?	Set to **y** to raise an event if the health state is `OK`. The default value is n.
Event severity when health state is OK	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 35.

77.29 JMSServersMsgsStored

Use this Knowledge Script to monitor JMS servers. This script monitors the number of messages on each JMS server. The time in threshold condition is the number of seconds in which the current number of messages is above or below a WebLogic Server threshold for that JMS server. This value, along with the current number of messages, can help you adjust the maximum messages for the JMS server.

77.29.1 Versions of WebLogic Supported

8.1 SP6, 9.0, 9.1, 9.2, and 10.x

77.29.2 Resource Object

WebLogic Server

77.29.3 Default Schedule

The default interval for this Knowledge Script is Every 15 minutes.

77.29.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default value is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default value is n.
Current messages threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the current number of messages stored on this JMS server, not including pending messages, exceeds this threshold, this Knowledge Script raises an event. The default value is –1.
Event severity when current messages exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Pending messages threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the current number of pending messages (unacknowledged or uncommitted) stored on this JMS server exceeds this threshold, this Knowledge Script raises an event. The default value is –1.
Event severity when pending messages exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Peak messages threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the peak number of messages stored on this JMS Server exceeds this threshold, this Knowledge Script raises an event. The default value is –1.

Description	How to Set It
Event severity when peak messages exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Time in threshold condition threshold in secs	Specify a threshold value using a real number greater than or equal to –1. Use –1 to ignore this threshold. If the number of seconds time spent in the threshold condition (due to the number of messages stored on this JMS server) exceeds this threshold, this Knowledge Script raises an event. The default value is 0.
Event severity when time in threshold condition exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.

77.30 JMSServersSessionPools

Use this Knowledge Script to monitor JMS servers. This script monitors the number of session pools in use by each JMS server and the rate at which those pools are being created.

77.30.1 Versions of WebLogic Supported

8.1 SP6, 9.0, 9.1, 9.2, and 10.x

77.30.2 Resource Object

WebLogic Server

77.30.3 Default Schedule

The default interval for this Knowledge Script is Every 15 minutes.

77.30.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default value is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default value is n.
Current session pools threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the current number of session pools instantiated on this JMS server exceeds this threshold, this Knowledge Script raises an event. The default value is –1.
Event severity when current session pools exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Peak session pools threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the peak number of session pools instantiated on this JMS server exceeds this threshold, this Knowledge Script raises an event. The default value is –1.
Event severity when peak session pools exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Session pools instantiated threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of session pools instantiated on this JMS server since the last sample exceeds this threshold, this Knowledge Script raises an event. The default value is –1.
Event severity when session pools instantiated bytes exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.

77.31 JRockitGC

Use this Knowledge Script to monitor the last time garbage collection was executed in the server and the total amount of time spent in garbage collection. These values will help determine potential bottlenecks within the WebLogic Server instance.

77.31.1 Versions of WebLogic Supported

8.1 SP6, 9.0, 9.1, 9.2, and 10.x

77.31.2 Resource Object

WebLogic Server

77.31.3 Default Schedule

The default interval for this Knowledge Script is Every 15 minutes.

77.31.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default value is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default value is n.
Seconds since last garbage collection ended threshold	Specify a threshold value using an integer value greater than or equal to –1. Use –1 to ignore this threshold. If the number of seconds since the last garbage collection run exceeds this threshold, this Knowledge Script raises an event. The default value is –1.
Event severity when seconds since last garbage collection exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Number of garbage collection runs threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of garbage collection runs since the last sample exceeds this threshold, this Knowledge Script raises an event. The default value is –1.
Event severity when number of garbage collection runs exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Average garbage collection time threshold in secs	Specify a threshold value using an integer value greater than or equal to –1. Use –1 to ignore this threshold. If the average time spent in a garbage collection run in seconds since the last sample exceeds this threshold, this Knowledge Script raises an event. The default value is 0.
Event severity when average garbage collection time exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.

77.32 JRockitThreads

Use this Knowledge Script to monitor the number of daemon threads and the total number of threads within the WebLogic Server. These values will help determine potential bottlenecks within the WebLogic Server instance.

77.32.1 Versions of WebLogic Supported

8.1 SP6, 9.0, 9.1, 9.2, and 10.x

77.32.2 Resource Object

WebLogic Server

77.32.3 Default Schedule

The default interval for this Knowledge Script is Every 15 minutes.

77.32.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default value is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default value is n.
Number of daemon threads threshold	Specify a threshold value using an integer value greater than or equal to –1. Use –1 to ignore this threshold. If the number of daemon threads exceeds this threshold, this Knowledge Script raises an event. The default value is –1.
Event severity when number of daemon threads exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Total number of threads threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the total number of threads exceeds this threshold, this Knowledge Script raises an event. The default value is –1.
Event severity when total number of threads exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.

77.33 JTAActiveTrans

Use this Knowledge Script to monitor the current number of transactions in progress on a WebLogic Server.

77.33.1 Versions of WebLogic Supported

8.1 SP6, 9.0, 9.1, 9.2, and 10.x

77.33.2 Resource Object

WebLogic Server

77.33.3 Default Schedule

The default interval for this Knowledge Script is Every 15 minutes.

77.33.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default value is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default value is n.
Active transactions threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of active transactions exceeds this threshold, this Knowledge Script raises an event. The default value is –1.
Event severity when active transactions exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.

77.34 JTACompletedTrans

Use this Knowledge Script to monitor the Java Transaction API (JTA). This script monitors the transactions that have completed on a WebLogic Server since the last sample. Transactions are rolled back when timeouts or application, system or resource errors occur. The JTATransRolledBack script provides a breakdown of the reasons for rollbacks.

77.34.1 Versions of WebLogic Supported

8.1 SP6, 9.0, 9.1, 9.2, and 10.x

77.34.2 Resource Object

WebLogic Server

77.34.3 Default Schedule

The default interval for this Knowledge Script is Every 15 minutes.

77.34.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default value is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default value is n.
Total transactions threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the total number of transactions since the last sample exceeds this threshold, this Knowledge Script raises an event. The default value is –1.
Event severity when total transactions exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Transactions committed threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of transactions committed since the last sample exceeds this threshold, this Knowledge Script raises an event. The default value is –1.
Event severity when transactions committed exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Transactions rolled back threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of transactions rolled back since the last sample exceeds this threshold, this Knowledge Script raises an event. The default value is 0.
Event severity when transactions rolled back exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.

Description	How to Set It
Heuristic completes threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of transactions with heuristic completes since the last sample exceeds this threshold, this Knowledge Script raises an event. The default value is –1.
Event severity when heuristic completes exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Average commit time threshold in secs	Specify a threshold value using a real number greater than or equal to –1. Use –1 to ignore this threshold. If the average commit time in seconds exceeds this threshold, this Knowledge Script raises an event. The default value is –1.
Event severity when average commit time exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Transactions abandoned threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of transactions abandoned since the last sample exceeds this threshold, this Knowledge Script raises an event. The default value is -1.
Event severity when transactions abandoned exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.

77.35 JTAHealthState

Use this Knowledge Script to monitor the health state of the JTA subsystem of a WebLogic Server.

77.35.1 Versions of WebLogic Supported

8.1 SP6, 9.0, 9.1, 9.2, and 10.x

77.35.2 Resource Object

WebLogic Server

77.35.3 Default Schedule

The default interval for this Knowledge Script is Every 15 minutes.

77.35.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Collect data?	Set to **y** to collect data for reports and graphs. The default value is n.
Scale to 100?	Set to y to scale the values to 100. The default values range from 0-3, where 0 is `OK`, and 3 is `FAIL`. Setting to y will scale the values from 0-100, where 0 is `FAIL` and 100 is `OK`. The default value is n.
Event for health state of FAIL?	Set to **y** to raise an event if the health state is `FAIL`. The default value is y.
Event severity when health state is FAIL?	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 5.
Event for health state of CRITICAL?	Set to **y** to raise an event if the health state is `CRITICAL`. The default value is y.
Event severity when health state is CRITICAL	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 15.
Event for health state of WARNING?	Set to **y** to raise an event if the health state is `WARNING`. The default value is y.
Event severity when health state is WARNING	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Event for health state of OK?	Set to **y** to raise an event if the health state is `OK`. The default value is n.
Event severity when health state is OK	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 35.

77.36 JTATransRolledBack

Use this Knowledge Script to obtain a breakdown of the reasons why transactions were rolled back.

77.36.1 Versions of WebLogic Supported

8.1 SP6, 9.0, 9.1, 9.2, and 10.x

77.36.2 Resource Object

WebLogic Server

77.36.3 Default Schedule

The default interval for this Knowledge Script is Every 15 minutes.

77.36.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default value is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default value is n.
Timeouts threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of rollbacks due to timeouts since the last sample exceeds this threshold, this Knowledge Script raises an event. The default value is 0.
Event severity when timeouts exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Resource errors threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of rollbacks due to resource errors since the last sample exceeds this threshold, this Knowledge Script raises an event. The default value is 0.
Event severity when resource errors exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Application errors threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of rollbacks due to application errors since the last sample exceeds this threshold, this Knowledge Script raises an event. The default value is 0.
Event severity when application errors exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.

Description	How to Set It
System errors threshold	Specify a threshold value using an integer greater than or equal to −1. Use −1 to ignore this threshold. If the number of rollbacks due to system errors since the last sample exceeds this threshold, this Knowledge Script raises an event. The default value is 0.
Event severity when system errors exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.

77.37 LogAccessLog

Use this Knowledge Script to monitor entries that are added to the Web server log of a WebLogic Server. The entries that are monitored can be restricted by supplying Perl regular expressions to indicate which entries should be included or excluded from consideration. The script checks only the new log entries that were created since the last time the script examined the log. By monitoring `access.log`, you can gather statistics on HTTP requests and sessions.

77.37.1 Versions of WebLogic Supported

8.1 SP6, 9.0, 9.1, 9.2, and 10.x

77.37.2 Resource Object

WebLogic Server

77.37.3 Default Schedule

The default interval for this Knowledge Script is Every 15 minutes.

77.37.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default value is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default value is n.
Number matched threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of log entries that matched the search criteria exceeds this threshold, this Knowledge Script raises an event. The default value is 0.
Event severity when number matched exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Include filter	Set to a string that is a regular expression that specifies the include filter.
Include modifier	Set to a string that is a modifier for the regular expression include filter. The default value is a null string.
Exclude filter	Set to a string that is a regular expression that specifies the exclude filter. The default value is a null string.
Exclude modifier	Set to a string that is a modifier for the regular expression exclude filter. The default value is a null string.

77.38 LogAccessLogSetPath

Use this Knowledge Script to set the absolute pathname for a Web server log file. The LogAccessLog Knowledge Script needs an absolute pathname for the log file, but the Administration Console of WebLogic Server will accept relative pathnames. This script provides a way to set the absolute path without having to do it through the Administration Console.

77.38.1 Versions of WebLogic Supported

8.1 SP6, 9.0, 9.1, 9.2, and 10.x

77.38.2 Resource Object

WebLogic Server

77.38.3 Default Schedule

The default interval for this Knowledge Script is Run once.

77.38.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default value is y.
Absolute path name for access.log file	The absolute pathname of the log file for the Web server.

77.39 LogWebLogic

Use this Knowledge Script to monitor entries that are added to the log for a WebLogic Server. The entries that are monitored can be restricted by supplying Perl regular expressions that indicate which entries should be included or excluded from consideration. The script checks only the new log entries that were created since the last time the script examined the log.

NOTE: If you are running WebLogic Server 8.1, you must specify an absolute path to the WebLogic log file in order to run the LogWebLogic Knowledge Script successfully. If the LogWebLogic script is run and you have not set an absolute path, you receive the following event message: 'Absolute pathname for log file required'. Use the LogWebLogicSetPath Knowledge Script to specify the absolute path to the WebLogic log file. You will continue to receive an event message until you reboot the WebLogic 8.1 server where the log file resides.

77.39.1 Versions of WebLogic Supported

8.1 SP6, 9.0, 9.1, 9.2, and 10.x

77.39.2 Resource Object

WebLogic Server

77.39.3 Default Schedule

The default interval for this Knowledge Script is Every 15 minutes.

77.39.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default value is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default value is n.
Number matched threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of log entries that matched the search criteria exceeds this threshold, this Knowledge Script raises an event. The default value is 0.
Event severity when number matched exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Include filter	Set to a string that is a regular expression that specifies the include filter. The default value is (*).
Include modifier	Set to a string that is a modifier for the regular expression include filter. The default value is a null string.

Description	How to Set It
Exclude filter	Set to a string that is a regular expression that specifies the exclude filter. The default value is a null string.
Exclude modifier	Set to a string that is a modifier for the regular expression exclude filter. The default value is a null string.

77.40 LogWebLogicSetPath

Use this Knowledge Script to set the absolute pathname for a WebLogic Server log file. The LogWebLogic Knowledge Script needs an absolute pathname for the log file, but the Administration Console of WebLogic Server will accept relative pathnames. This script provides a way to set the absolute path without having to do it through the Administration Console.

77.40.1 Versions of WebLogic Supported

9.0, 9.1, 9.2, and 10.x

77.40.2 Resource Object

WebLogic Server

77.40.3 Default Schedule

The default interval for this Knowledge Script is Run once.

77.40.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default value is y.
Absolute path name for WebLogic Server log file	The absolute pathname of the WebLogic Server's log file.

77.41 Memory

Use this Knowledge Script to monitor the physical and virtual memory use of a WebLogic Server.

77.41.1 Versions of WebLogic Supported

8.1 SP6, 9.0, 9.1, 9.2, and 10.x

77.41.2 Resource Object

WebLogic Server

77.41.3 Default Schedule

The default interval for this Knowledge Script is Every 15 minutes.

77.41.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default value is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default value is n.
Real memory size threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the real memory size of a WebLogic Server in kilobytes exceeds this threshold, this Knowledge Script raises an event. The default value is –1.
Event severity when real memory size exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Virtual memory size threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the virtual memory size of a WebLogic Server in kilobytes exceeds this threshold, this Knowledge Script raises an event. The default value is –1.
Event severity when virtual memory size exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Percent of real memory in use threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the percent of real memory in use of a WebLogic Server in kilobytes exceeds this threshold, this Knowledge Script raises an event. The default value is –1.
Event severity when percent of real memory in use exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.

77.42 MsgDrivenEJBError

Use this Knowledge Script to monitor errors generated by a message-driven EJB. This script reports error statistics for a message-driven EJB.

This script may be used to determine the number of times the message-driven EJB was destroyed due to an exception, and the number of failed attempts to retrieve an EJB from the pool. These values will help monitor the message-driven EJB if errors occur.

77.42.1 Versions of WebLogic Supported

8.1 SP6, 9.0, 9.1, 9.2, and 10.x

77.42.2 Resource Object

WebLogic Server

77.42.3 Default Schedule

The default interval for this Knowledge Script is Every 15 minutes.

77.42.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default value is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default value is n.
Destroyed bean instances threshold	Specify a threshold value using an integer value greater than or equal to –1. Use –1 to ignore this threshold. If the number of times since the last sample that a bean instance was destroyed due to a thrown exception exceeds this threshold, this Knowledge Script raises an event. The default value is 0.
Event severity when destroyed bean instances exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Miss count threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of failed attempts to retrieve a bean from the free pool since the last sample exceeds this threshold, this Knowledge Script raises an event. The default value is 0.
Event severity when miss count exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.

77.43 MsgDrivenEJBPool

Use this Knowledge Script to monitor for the number or percentage of beans that are in use and idle in a message-driven EJB pool. These values will help determine if the size of the pool has been set properly.

77.43.1 Versions of WebLogic Supported

8.1 SP6, 9.0, 9.1, 9.2, and 10.x

77.43.2 Resource Object

WebLogic Server

77.43.3 Default Schedule

The default interval for this Knowledge Script is Every 15 minutes.

77.43.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default value is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default value is n.
Beans idle threshold	Specify a threshold value using an integer greater than or equal to -1. Use -1 to ignore this threshold. If the number of beans that are allocated but idle exceeds this threshold, this Knowledge Script raises an event. The default value is -1.
Event severity when beans idle exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Beans in use threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of beans in use exceeds this threshold, this Knowledge Script raises an event. The default value is –1.
Event severity when beans in use exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Percent of pool in use threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the percent of beans available in the pool in use exceeds this threshold, this Knowledge Script raises an event. The default value is –1.
Event severity when percent of pool in use exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.

77.44 MsgDrivenEJBTrans

Use this Knowledge Script to monitor a message-driven EJB. This script monitors the transaction rates for a message-driven EJB. Transactions are rolled back when timeouts or application, system or resource errors occur. The JTATransRolledBack Knowledge Script provides a breakdown of the reasons for rollbacks.

77.44.1 Versions of WebLogic Supported

8.1 SP6, 9.0, 9.1, 9.2, and 10.x

77.44.2 Resource Object

WebLogic Server

77.44.3 Default Schedule

The default interval for this Knowledge Script is Every 15 minutes.

77.44.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default value is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default value is n.
Transactions committed threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of transactions committed since the last sample exceeds this threshold, this Knowledge Script raises an event. The default value is –1.
Event severity when transactions committed exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Transactions rolled back threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of transactions rolled back since the last sample exceeds this threshold, this Knowledge Script raises an event. The default value is 0.
Event severity when transactions rolled back exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Transactions timed out threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of transactions timed out since the last sample exceeds this threshold, this Knowledge Script raises an event. The default value is 0.
Event severity when transactions timed out exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.

77.45 MsgDrivenEJBWait

Use this Knowledge Script to monitor a message-driven EJB. This script monitors the number of times a request had to wait for an EJB and the number of times a request timed out waiting for an EJB. Increasing the cache size may help reduce the number of timeouts.

77.45.1 Versions of WebLogic Supported

8.1 SP6, 9.0, 9.1, 9.2, and 10.x

77.45.2 Resource Object

WebLogic Server

77.45.3 Default Schedule

The default interval for this Knowledge Script is Every 15 minutes.

77.45.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default value is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default value is n.
Times waited threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of times since the last sample that clients have waited for a bean exceeds this threshold, this Knowledge Script raises an event. The default value is –1.
Event severity when times waited exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Timeouts threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of timeouts since the last sample exceeds this threshold, this Knowledge Script raises an event. The default value is 0.
Event severity when timeouts exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.

77.46 NetIQAgent

Use this Knowledge Script to stop (and start) the NetIQ UNIX agent, which most of the scripts use to gather information from WebLogic servers.

77.46.1 Versions of WebLogic Supported

8.1 SP6, 9.0, 9.1, 9.2, and 10.x

77.46.2 Resource Object

WebLogic Server

77.46.3 Default Schedule

The default interval for this Knowledge Script is Run once.

77.46.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default value is y.
Event severity when NetIQ WebLogic agent cannot be started	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 10.
Event severity when NetIQ WebLogic agent cannot be stopped	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 15.
Event severity when NetIQ WebLogic agent is started	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Event severity when NetIQ WebLogic agent is stopped	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Enable?	Set to **y** to start the NetIQ UNIX agent; set to n to stop it. The default value is y.

77.47 Report_HealthSummary

Use this Report Knowledge Script to generate a report summarizing the health of monitored WebLogic servers. The report provides data gathered by the HealthCheck Knowledge Script.

77.47.1 Resource Object

AppManager repository

77.47.2 Default Schedule

The default schedule for this Knowledge Script is **Run once**.

77.47.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Data source	Use the following parameters to select the data for your report.
Select computer(s)	Click the **Browse [...]** button to start the data wizard. Use the data wizard to select the computers for your report.
Select time range	Click the **Browse (...)** button to open the time browser. Set a specific or sliding time range for data included in your report.
Select peak weekday(s)	Click the **Browse (...)** button to select the days of the week to include in your report.
Aggregation by	Select the time period (Hour, Minute, or Day) by which the data in your report is aggregated.
Aggregation interval	Select the interval between aggregations of the data in your report. This parameter uses the time period specified in the **Aggregation by** parameter to calculate the interval.
Report Component Selection	Use the following parameters to define which data and statistics are displayed in the report.
Include parameter card?	Set to **y** to include a table in the report that lists parameter settings for the report script. The default value is y.
Include Running detail table?	Set to **y** to include data from the Availability detail table in the report. The default value is y.
Include Running chart?	Set to **y** to include data from the Availability chart in the report. The default value is y.
Threshold on running chart	Specify an integer to set a threshold for the Availability chart. Use -1 to ignore this threshold.
Include WebLogic Ping Response Time detail table?	Set to **y** to include data from the WebLogic Ping Response Time detail table in the report. The default value is y.

Description	How to Set It
Include WebLogic Ping Response Time chart?	Set to **y** to include data from the WebLogic Ping Response Time chart in the report. The default value is y.
Units for WebLogic Ping Response Time report	Select the measurement units to be used in the WebLogic Ping Response Time report. The default value is msec (milliseconds).
Threshold on WebLogic Ping Response Time chart	Specify an integer to set a threshold for the WebLogic Ping Response Time chart. Use -1 to ignore this threshold. The default value is 0.
Include WebLogic Connect Time detail table?	Set to **y** to include data from the WebLogic Connect Time detail table in the report. The default value is y.
Include WebLogic Connect Time chart?	Set to **y** to include data from the WebLogic Connect Time chart in the report. The default value is y.
Units for WebLogic Connect Time report	Select the measurement units to be used in the WebLogic Connect Time report. The default value is msec (milliseconds).
Threshold on WebLogic Connect Time chart	Specify an integer to set a threshold for the WebLogic Connect Time chart. Use -1 to ignore this threshold. The default value is 0.
Report settings	Use the following parameters to define the graphical presentation of data, the folder where the report is generated, and properties that identify the report.
Customize chart appearance	Click the **Browse (...)** button to open the Chart Settings window. Define the graphic properties of the charts in your report. The default value is Ribbon.
Select report location	Click the **Browse (...)** button to open the Publishing Options window. Define the report filename and specify a default folder this report. The default value is WebLogicSvrUnix_HealthSummary
Add job ID to output folder name?	Set to **y** to append the job ID to the name of the output folder. This is helpful to make the correlation between a specific instance of a Report Script and the corresponding report. The default value is n.
Index-Report Title	Click in the Value column, and click the **Browse (...)** button to open the Report Properties window. Set the properties parameters as desired The default title is WebLogicSvrUnix_HealthSummary.
Add time stamp to title?	Set to y to append a time stamp to the title of the report, making each title unique. The time stamp is made up of the date and time the report was generated. Adding a time stamp is useful in order to run consecutive iterations of the same report without overwriting previous output. The default value is n.
Event notification	Use the following parameters to raise events associated with generating the report, and to set severity levels for those events.

Description	How to Set It
Generate event on success?	Set to **y** to raise an event when the report is successfully generated. The default value is y.
Severity level for report success	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 35 (magenta level indicator).
Severity level for report with no data	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25 (blue level indicator).
Severity level for report failure.	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 5 (red level indicator).

77.48 Report_PerfSummary

Use this Report Knowledge Script to generate a report summarizing the throughput performance of monitored WebLogic servers. The report provides data from the ServerCPU and ServerRequests Knowledge Scripts.

77.48.1 Resource Object

AppManager repository

77.48.2 Default Schedule

The default schedule for this Knowledge Script is **Run once**.

77.48.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Data source	Use the following parameters to select the data for your report.
Select computer(s)	Click the **Browse [...]** button to start the data wizard. Use the data wizard to select the computers for your report.
Select time range	Click the **Browse (...)** button to open the time browser. Set a specific or sliding time range for data included in your report.
Select peak weekday(s)	Click the **Browse (...)** button to select the days of the week to include in your report.
Aggregation by	Select the time period (Hour, Minute, or Day) by which the data in your report is aggregated.
Aggregation interval	Select the interval between aggregations of the data in your report. This parameter uses the time period specified in the “Aggregation by” parameter to calculate the interval.
Report Component Selection	Use the following parameters to define which data and statistics are displayed in the report.
Include parameter card?	Set to **y** to include a table in the report that lists parameter settings for the report script. The default value is y.
Include CPU Utilization detail table?	Set to **y** to include data from the CPU Utilization detail table in the report. The default value is y.
Include CPU Utilization chart?	Set to **y** to include data from the CPU Utilization chart in the report. The default value is y.
Threshold on CPU Utilization chart?	Specify an integer to set a threshold for the CPU Utilization chart. Use -1 to ignore this threshold. The default value is 0.
Include Throughput detail table?	Set to **y** to include data from the Throughput detail table in the report. The default value is y.

Description	How to Set It
Include Throughput chart?	Set to **y** to include data from the Throughput chart in the report. The default value is y.
Threshold on Throughput chart	Specify an integer to set a threshold for the Throughput chart. Use -1 to ignore this threshold. The default value is 0.
Report settings	Use the following parameters to define the graphical presentation of data, the folder where the report is generated, and properties that identify the report.
Customize chart appearance	Click the **Browse (...)** button to open the Chart Settings window. Define the graphic properties of the charts in your report. The default value is Ribbon.
Select report location	Click the **Browse (...)** button to open the Publishing Options window. Define the report filename and specify a default folder this report. The default value is WebLogicSvrUnix_PerfSummary.
Add job ID to output folder name?	Set to **y** to append the job ID to the name of the output folder. This is helpful to make the correlation between a specific instance of a Report Script and the corresponding report. The default value is n.
Index-Report Title	Click in the Value column, and click the **Browse (...)** button to open the Report Properties window. Set the properties parameters as desired. The default title is WebLogicSvrUnix_Perf Summary.
Add time stamp to title?	Set to **y** to append a time stamp to the title of the report, making each title unique. The time stamp is made up of the date and time the report was generated. Adding a time stamp is useful in order to run consecutive iterations of the same report without overwriting previous output. The default value is n.
Event notification	Use the following parameters to raise events associated with generating the report, and to set severity levels for those events.
Generate event on success?	Set to **y** to raise an event when the report is successfully generated. The default value is y.
Severity level for report success	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 35 (magenta level indicator).
Severity level for report with no data	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25 (blue level indicator).
Severity level for report failure.	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 5 (red level indicator).

77.49 SecurityUserLockout

Use this Knowledge Script to monitor statistics on the number of users locked out because invalid usernames and/or passwords were supplied at login.

77.49.1 Versions of WebLogic Supported

8.1 SP6, 9.0, 9.1, 9.2, and 10.x

77.49.2 Resource Object

WebLogic Server

77.49.3 Default Schedule

The default interval for this Knowledge Script is Every 15 minutes.

77.49.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default value is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default value is n.
User lockouts threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of user lockouts since the last sample exceeds this threshold, this Knowledge Script raises an event. The default value is 0.
Event severity when user lockouts exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Invalid logins threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of invalid logins since the last sample exceeds this threshold, this Knowledge Script raises an event. The default value is 0.
Event severity when invalid logins exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Invalid logins while user locked out threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of invalid logins while a user was locked out since the last sample exceeds this threshold, this Knowledge Script raises an event. The default value is 0.
Event severity when invalid logins while user locked out exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.

Description	How to Set It
User unlocks threshold	Specify a threshold value using an integer greater than or equal to −1. Use −1 to ignore this threshold. If the number of times since the last sample that a user was unlocked exceeds this threshold, this Knowledge Script raises an event. The default value is −1.
Event severity when user unlocks exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Locked users threshold	Specify a threshold value using an integer greater than or equal to −1. Use −1 to ignore this threshold. If the current number of locked users exceeds this threshold, this Knowledge Script raises an event. The default value is 0.
Event severity when locked users exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.

77.50 ServerCPU

Use this Knowledge Script to monitor the utilization of a WebLogic Server. This script monitors the amount of CPU the server is consuming.

This script may be used to track how busy a server is at a given time.

77.50.1 Versions of WebLogic Supported

8.1 SP6, 9.0, 9.1, 9.2, and 10.x

77.50.2 Resource Object

WebLogic Server

77.50.3 Default Schedule

The default interval for this Knowledge Script is Every 15 minutes.

77.50.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default value is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default value is n.
CPU usage threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the CPU utilization for the WebLogic Server exceeds this threshold, this Knowledge Script raises an event. The default value is –1.
Event severity when CPU usage exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.

77.51 ServerHealthState

Use this Knowledge Script to monitor the health state of a WebLogic Server.

77.51.1 Versions of WebLogic Supported

8.1 SP6, 9.0, 9.1, 9.2, and 10.x

77.51.2 Resource Object

WebLogic Server

77.51.3 Default Schedule

The default interval for this Knowledge Script is Every 15 minutes.

77.51.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Collect data?	Set to **y** to collect data for reports and graphs. The default value is n.
Scale to 100?	Set to **y** to scale the values to 100. The default values range from 0-3, where 0 is `OK`, and 3 is `FAIL`. Setting to y will scale the values from 0-100, where 0 is `FAIL` and 100 is `OK`. The default value is n.
Event for health state of FAIL?	Set to **y** to raise an event if the health state is `FAIL`. The default value is y.
Event severity when health state is FAIL?	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 5.
Event for health state of CRITICAL?	Set to **y** to raise an event if the health state is `CRITICAL`. The default value is y.
Event severity when health state is CRITICAL	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 15.
Event for health state of WARNING?	Set to **y** to raise an event if the health state is `WARNING`. The default value is y.
Event severity when health state is WARNING	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Event for health state of OK?	Set to **y** to raise an event if the health state is `OK`. The default value is n.
Event severity when health state is OK	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 35.

77.52 ServerJVMHeap

Use this Knowledge Script to monitor the utilization of a WebLogic Server. This script monitors the percentage of a WebLogic server's JVM heap that is currently used. If this value is consistently near 100%, consider increasing the size of the WebLogic server's JVM heap.

77.52.1 Versions of WebLogic Supported

8.1 SP6, 9.0, 9.1, 9.2, and 10.x

77.52.2 Resource Object

WebLogic Server

77.52.3 Default Schedule

The default interval for this Knowledge Script is Every 15 minutes.

77.52.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default value is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default value is n.
Heap size threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the current size of the heap in KB exceeds this threshold, this Knowledge Script raises an event. The default value is –1.
Event severity when heap size exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Free heap threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of KB available in the heap falls below this threshold, this Knowledge Script raises an event. The default value is –1.
Event severity when free heap falls below threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Percent heap used threshold	Specify a threshold value using a real number greater than or equal to –1. Use –1 to ignore this threshold. If the percentage of the JVM Heap that is currently used exceeds this threshold, this Knowledge Script raises an event. The default value is –1.
Event severity when percent heap used exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.

77.53 ServerRequests

Use this Knowledge Script to monitor the utilization and throughput of a WebLogic Server. This script monitors the server's Execute Queue.

This script may be used to track how busy a server is at a given time.

NOTE: If the number of requests waiting on the Execute Queue is 0, the value for the "Oldest request" on the queue is not returned and the threshold comparison is not performed.

77.53.1 Versions of WebLogic Supported

8.1 SP6, 9.0, 9.1, 9.2, and 10.x

77.53.2 Resource Object

WebLogic Server

77.53.3 Default Schedule

The default interval for this Knowledge Script is Every 15 minutes.

77.53.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default value is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default value is n.
Throughput threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of requests the WebLogic Server has serviced since the last sample exceeds this threshold, this Knowledge Script raises an event. The default value is –1.
Event severity when throughput exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Waiting requests threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of requests waiting on the Execute Queue exceeds this threshold, this Knowledge Script raises an event. The default value is –1.
Event severity when waiting requests exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.

Description	How to Set It
Oldest request threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of seconds the oldest request has been on the Execute Queue exceeds this threshold, this Knowledge Script raises an event. The default value is –1.
Event severity when oldest request exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Idle threads threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of idle threads in the Execute Queue exceeds this threshold, this Knowledge Script raises an event. The default value is –1.
Event severity when idle threads exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Percent threads in use threshold	Specify a threshold value using an integer greater than or equal to –1 and less than or equal to 100. Use –1 to ignore this threshold. If the percent of threads in the Execute Queue exceeds this threshold, this Knowledge Script raises an event. The default value is –1.
Event severity when percent threads in use exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.

77.54 ServerSecurity

Use this Knowledge Script to monitor statistics on the number of users locked out because invalid usernames and/or passwords were supplied at login.

77.54.1 Versions of WebLogic Supported

8.1 SP6, 9.0, 9.1, 9.2, and 10.x

77.54.2 Resource Object

WebLogic Server

77.54.3 Default Schedule

The default interval for this Knowledge Script is Every 15 minutes.

77.54.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default value is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default value is n.
User lockouts threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of user lockouts since the last sample exceeds this threshold, this Knowledge Script raises an event. The default value is 0.
Event severity when user lockouts exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Invalid logins threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of invalid logins since the last sample exceeds this threshold, this Knowledge Script raises an event. The default value is 0.
Event severity when invalid logins exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Invalid logins while user locked out threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of invalid logins while a user was locked out since the last sample exceeds this threshold, this Knowledge Script raises an event. The default value is 0.
Event severity when invalid logins while user locked out exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.

Description	How to Set It
User unlocks threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of times since the last sample that a user was unlocked exceeds this threshold, this Knowledge Script raises an event. The default value is –1.
Event severity when user unlocks exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Locked users threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the current number of locked users exceeds this threshold, this Knowledge Script raises an event. The default value is 0.
Event severity when locked users exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.

77.55 ServerSockets

Use this Knowledge Script to monitor the number of sockets a WebLogic Server has open.

This script may be used to track the number of server connections and how busy a WebLogic Server is.

77.55.1 Versions of WebLogic Supported

8.1 SP6, 9.0, 9.1, 9.2, and 10.x

77.55.2 Resource Object

WebLogic Server

77.55.3 Default Schedule

The default interval for this Knowledge Script is Every 15 minutes.

77.55.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default value is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default value is n.
Sockets currently open threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of sockets currently open exceeds this threshold, this Knowledge Script raises an event. The default value is –1.
Event severity when sockets currently open exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Total sockets opened threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of sockets opened since the last sample exceeds this threshold, this Knowledge Script raises an event. The default value is –1.
Event severity when total sockets opened exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.

77.56 ServerState

Use this Knowledge Script to monitor the state of a WebLogic Server as reported by the WebLogic Server. If the state is anything other than RUNNING, the server may not be responding properly.

77.56.1 Versions of WebLogic Supported

8.1 SP6, 9.0, 9.1, 9.2, and 10.x

77.56.2 Resource Object

WebLogic Server

77.56.3 Default Schedule

The default interval for this Knowledge Script is Every 15 minutes.

77.56.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Collect data?	Set to **y** to collect data for reports and graphs. The default value is n.
Event for any state other than RUNNING?	Set to **y** to raise an event if the health state is not RUNNING. The default value is y.
Event severity when health state is not RUNNING?	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 5.
Event for state of RUNNING?	Set to **y** to raise an event if the state is RUNNING. The default value is n.
Event severity when state is RUNNING	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 35.

77.57 ServerUptime

Use this Knowledge Script to monitor how many hours a WebLogic Server has been running.

77.57.1 Versions of WebLogic Supported

8.1 SP6, 9.0, 9.1, 9.2, and 10.x

77.57.2 Resource Object

WebLogic Server

77.57.3 Default Schedule

The default interval for this Knowledge Script is Every 15 minutes.

77.57.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default value is y.
Maximum server up time threshold	Specify a threshold value using a real number greater than or equal to –1. Use –1 to ignore this threshold. If the overall average execution time (in seconds) of the servlet exceeds this threshold, this Knowledge Script raises an event. The default value is –1.
Collect data?	Set to **y** to collect data for reports and graphs. The default value is n.
Event severity when server has restarted	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.

77.58 ServletExecTime

Use this Knowledge Script to monitor the execution times and number of times that the servlets of a Web application were invoked. The short-term average is the average execution time since the last sample; the long-term average is the average execution time since the WebLogic server was started.

The overall average execution time of a servlet is calculated as the total time that the servlet has run since the WebLogic server was started, divided by the total number of times the servlet was invoked since the WebLogic server was started. This average will not tend to change very much if the WebLogic server has been running for a long time.

The short-term average execution time of a servlet is calculated as the time that the servlet has run since the last sample, divided by the number of times the servlets was invoked since the last sample. This average gives a better impression of how well the servlet has been performing since the last sample.

77.58.1 Versions of WebLogic Supported

8.1 SP6, 9.0, 9.1, 9.2, and 10.x

77.58.2 Resource Object

WebLogic Server

77.58.3 Default Schedule

The default interval for this Knowledge Script is Every 15 minutes.

77.58.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default value is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default value is n.
Overall average threshold in secs	Specify a threshold value using a real number greater than or equal to –1. Use –1 to ignore this threshold. If the overall average execution time (in seconds) of the servlet exceeds this threshold, this Knowledge Script raises an event. The default value is –1.
Event severity when overall average exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Short term average threshold in secs	Specify a threshold value using a real number greater than or equal to –1. Use –1 to ignore this threshold. If the short-term average execution time (in seconds) of the servlet exceeds this threshold, this Knowledge Script raises an event. The default value is –1.

Description	How to Set It
Event severity when short-term average exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Longest time threshold in secs	Specify a threshold value using a real number greater than or equal to –1. Use –1 to ignore this threshold. If the longest execution time (in seconds) of the servlet exceeds this threshold, this Knowledge Script raises an event. The default value is –1.
Event severity when longest time exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Shortest time threshold	Specify a threshold value using a real number greater than or equal to –1. Use –1 to ignore this threshold. If the shortest execution time (in seconds) of the servlet exceeds this threshold, this Knowledge Script raises an event. The default value is –1.
Event severity when shortest time exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Invocations threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of invocations of the servlet since the last sample exceeds this threshold, this Knowledge Script raises an event. The default value is –1.
Event severity when invocations exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Reloads threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of reloads of the servlet since the last sample exceeds this threshold, this Knowledge Script raises an event. The default value is –1.
Event severity when reloads exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.

77.59 StartAdminServer

Use this Knowledge Script to start a WebLogic Server as the Administration Server for a domain.

77.59.1 Versions of WebLogic Supported

8.1 SP6, 9.0, 9.1, 9.2, and 10.x

77.59.2 Resource Object

WebLogic Server

77.59.3 Default Schedule

The default interval for this Knowledge Script is Run once.

77.59.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default value is y.
Event severity when script fails	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 10.
Event severity when server cannot be started	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 10.
Event severity when server is started	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Start Script	Enter the name (with the full path) of the script that you use to start an Administration Server. The default value is blank (no default). This is a mandatory field.
Start Script Parameters	Enter the parameters for the start script, if any.
Restart server if already running? (y/n)	Set to **y** to restart the server if it is already running. The default value is y.
Pass name of server, IP address, port, admin username and password to Start Script?	Set to **y** to pass these parameters to the Start Script. These parameters will be added to the end of the string supplied for Start Script. The default value is n.
Start time limit	Set to the number of seconds within which the WebLogic Server should complete initialization. The default value is 300.

77.60 StartServer

Use this Knowledge Script to start a managed WebLogic Server.

77.60.1 Versions of WebLogic Supported

8.1 SP6, 9.0, 9.1, 9.2, and 10.x

77.60.2 Resource Object

WebLogic Server

77.60.3 Default Schedule

The default interval for this Knowledge Script is Run once.

77.60.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default value is y.
Event severity when server cannot be started	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 10.
Event severity when server is started	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Start Script	Set to the name of the script that you use to start an Administration Server. The default value is blank (no default).
Start Script Parameters	Enter the parameters for the start script, if any.
Restart server if already running?	Set to **y** to restart the server if it is already running. The default value is y.
Pass name of server, IP address, port, admin username and password to Start Script?	Set to **y** to pass these parameters to the Start Script. These parameters will be added to the end of the string supplied for Start Script. The default value is n.
Start time limit	Set to the number of seconds within which the WebLogic Server should complete initialization. The default value is 300.

77.61 StartServerNodeMgr

Use this Knowledge Script to start WebLogic Server as a Managed Server using the Node Manager.

77.61.1 Versions of WebLogic Supported

8.1 SP6, 9.0, 9.1, 9.2, and 10.x

77.61.2 Resource Object

WebLogic Server

77.61.3 Default Schedule

The default interval for this Knowledge Script is Run once.

77.61.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default value is y.
Event severity when server cannot be started	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 10.
Event severity when server is started	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Restart server if already running?	Set to **y** to restart the server if it is already running. The default value is y.

77.62 StatefulEJBCache

Use this Knowledge Script to monitor statistics for a Stateful EJB. This script reports caching statistics for a Stateful EJB.

This script may be used to determine a cache hit ratio and how frequently instances of the Stateful EJB are rendered active or passive. These values will help determine if the size of the cache is appropriate.

77.62.1 Versions of WebLogic Supported

8.1 SP6, 9.0, 9.1, 9.2, and 10.x

77.62.2 Resource Object

WebLogic Server

77.62.3 Default Schedule

The default interval for this Knowledge Script is Every 15 minutes.

77.62.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default value is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default value is n.
Current beans threshold	Specify a threshold value using an integer value greater than or equal to –1. Use –1 to ignore this threshold. If the number of beans currently in use exceeds this threshold, this Knowledge Script raises an event. The default value is –1.
Event severity when current beans exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Cache accesses threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of cache accesses since the last sample exceeds this threshold, this Knowledge Script raises an event. The default value is –1.
Event severity when cache accesses exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Cache hit ratio threshold	Specify a threshold value using a real number greater than or equal to –1. Use –1 to ignore this threshold. If the cache hit ratio (expressed as a percentage) since the last sample falls below this threshold, this Knowledge Script raises an event. The default value is –1.
Event severity when cache hit ratio falls below threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.

Description	How to Set It
Activations threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of activations since the last sample exceeds this threshold, this Knowledge Script raises an event. The default value is –1.
Event severity when activations exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Passivations threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of passivations since the last sample exceeds this threshold, this Knowledge Script raises an event. The default value is –1.
Event severity when passivations exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Cache miss count threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the cache miss count since the last sample exceeds this threshold, this Knowledge Script raises an event. The default value is –1.
Event severity when cache miss count exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.

77.63 StatefulEJBTrans

Use this Knowledge Script to monitor Stateful EJBs. This script monitors the transaction rates for a Stateful EJB. Transactions are rolled back when timeouts or application, system, or resource errors occur. The JTATransRolledBack Knowledge Script provides a breakdown of the reasons for rollbacks.

77.63.1 Versions of WebLogic Supported

8.1 SP6, 9.0, 9.1, 9.2, and 10.x

77.63.2 Resource Object

WebLogic Server

77.63.3 Default Schedule

The default interval for this Knowledge Script is Every 15 minutes.

77.63.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default value is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default value is n.
Transactions committed threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of transactions committed since the last sample exceeds this threshold, this Knowledge Script raises an event. The default value is –1.
Event severity when transactions committed exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Transactions rolled back threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of transactions rolled back since the last sample exceeds this threshold, this Knowledge Script raises an event. The default value is 0.
Event severity when transactions rolled back exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Transactions timed out threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of transactions timed out since the last sample exceeds this threshold, this Knowledge Script raises an event. The default value is 0.
Event severity when transactions timed out exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.

77.64 StatefulEJBWait

Use this Knowledge Script to monitor Stateful EJBs. This script monitors the number of times a request had to wait for an EJB and the number of times a request timed out waiting for an EJB. Increasing the cache size may help reduce the number of timeouts.

77.64.1 Versions of WebLogic Supported

8.1 SP6, 9.0, 9.1, 9.2, and 10.x

77.64.2 Resource Object

WebLogic Server

77.64.3 Default Schedule

The default interval for this Knowledge Script is Every 15 minutes.

77.64.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default value is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default value is n.
Times waited threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of times since the last sample that clients have waited for a bean exceeds this threshold, this Knowledge Script raises an event. The default value is –1.
Event severity when times waited exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Timeouts threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of timeouts since the last sample exceeds this threshold, this Knowledge Script raises an event. The default value is 0.
Event severity when timeouts exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.

77.65 StatelessEJBError

Use this Knowledge Script to monitor errors generated by a Stateless EJB. This script reports error statistics for a Stateless EJB.

This script may be used to determine the number of times the Stateless EJB was destroyed due to an exception, and the number of failed attempts to retrieve an EJB from the pool. These values will help monitor the Stateless EJB if errors occur.

77.65.1 Versions of WebLogic Supported

8.1 SP6, 9.0, 9.1, 9.2, and 10.x

77.65.2 Resource Object

WebLogic Server

77.65.3 Default Schedule

The default interval for this Knowledge Script is Every 15 minutes.

77.65.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default value is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default value is n.
Destroyed bean instances threshold	Specify a threshold value using an integer value greater than or equal to –1. Use –1 to ignore this threshold. If the number of times since the last sample that a bean instance was destroyed due to a thrown exception exceeds this threshold, this Knowledge Script raises an event. The default value is 0.
Event severity when destroyed bean instances exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Miss count threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of failed attempts to retrieve a bean from the free pool since the last sample exceeds this threshold, this Knowledge Script raises an event. The default value is 0.
Event severity when miss count exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.

77.66 StatelessEJBPool

Use this Knowledge Script to monitor for the number or percentage of in-use and idle beans in a Stateless EJB pool. These values will help determine if the size of the pool has been set properly.

77.66.1 Versions of WebLogic Supported

8.1 SP6, 9.0, 9.1, 9.2, and 10.x

77.66.2 Resource Object

WebLogic Server

77.66.3 Default Schedule

The default interval for this Knowledge Script is Every 15 minutes.

77.66.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default value is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default value is n.
Beans idle threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of beans that are allocated but idle exceeds this threshold, this Knowledge Script raises an event. The default value is –1.
Event severity when beans idle exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Beans in use threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of beans in use exceeds this threshold, this Knowledge Script raises an event. The default value is –1.
Event severity when beans in use exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Percent of pool in use threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the percentage of beans in the pool that are in use exceeds this threshold, this Knowledge Script raises an event. The default value is –1.
Event severity when percent of pool in use exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.

77.67 StatelessEJBTrans

Use this Knowledge Script to monitor Stateless EJBs. This script monitors the transaction rates for a Stateless EJB. Transactions are rolled back when timeouts or application, system or resource errors occur. The JTATransRolledBack Knowledge Script provides a breakdown of the reasons for rollbacks.

77.67.1 Versions of WebLogic Supported

8.1 SP6, 9.0, 9.1, 9.2, and 10.x

77.67.2 Resource Object

WebLogic Server

77.67.3 Default Schedule

The default interval for this Knowledge Script is Every 15 minutes.

77.67.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default value is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default value is n.
Transactions committed threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of transactions committed since the last sample exceeds this threshold, this Knowledge Script raises an event. The default value is –1.
Event severity when transactions committed exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Transactions rolled back threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of transactions rolled back since the last sample exceeds this threshold, this Knowledge Script raises an event. The default value is 0.
Event severity when transactions rolled back exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Transactions timed out threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of transactions timed out since the last sample exceeds this threshold, this Knowledge Script raises an event. The default value is 0.
Event severity when transactions timed out exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.

77.68 StatelessEJBWait

Use this Knowledge Script to monitor Stateless EJBs. This script monitors the number of times a request had to wait for an EJB and the number of times a request timed out waiting for an EJB. Increasing the cache size may help reduce the number of timeouts.

77.68.1 Versions of WebLogic Supported

8.1 SP6, 9.0, 9.1, 9.2, and 10.x

77.68.2 Resource Object

WebLogic Server

77.68.3 Default Schedule

The default interval for this Knowledge Script is Every 15 minutes.

77.68.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default value is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default value is n.
Times waited threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of times since the last sample that clients have waited for a bean exceeds this threshold, this Knowledge Script raises an event. The default value is –1.
Event severity when times waited exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Timeouts threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of timeouts since the last sample exceeds this threshold, this Knowledge Script raises an event. The default value is 0.
Event severity when timeouts exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.

77.69 StopServer

Use this Knowledge Script to shut down a WebLogic Server.

77.69.1 Versions of WebLogic Supported

8.1 SP6, 9.0, 9.1, 9.2, and 10.x

77.69.2 Resource Object

WebLogic Server

77.69.3 Default Schedule

The default interval for this Knowledge Script is Run once.

77.69.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default value is y.
Event severity when unable to stop server	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 10.
Event severity when server is stopped	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.

77.70 TransCateg

Use this Knowledge Script to monitor statistics for transaction categories. This script monitors the transactions that have completed on a WebLogic Server since the last sample on a per transaction category basis. Transactions are rolled back when timeouts or application, system or resource errors occur. The TransCategRollBacks Knowledge Script provides a breakdown of the reasons for rollbacks.

77.70.1 Versions of WebLogic Supported

8.1 SP6, 9.0, 9.1, 9.2, and 10.x

77.70.2 Resource Object

WebLogic Server

77.70.3 Default Schedule

The default interval for this Knowledge Script is Every 15 minutes.

77.70.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default value is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default value is n.
Transactions completed threshold	Specify a threshold value using an integer greater than or equal to -1. Use -1 to ignore this threshold. If the number of transactions completed since the last sample exceeds this threshold, this Knowledge Script raises an event. The default value is -1.
Event severity when transactions completed exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Transactions committed threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of transactions committed since the last sample exceeds this threshold, this Knowledge Script raises an event. The default value is –1.
Event severity when transactions committed exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Transactions rolled back threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of transactions rolled back since the last sample exceeds this threshold, this Knowledge Script raises an event. The default value is 0.

Description	How to Set It
Event severity when transactions rolled back exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Average commit time threshold in secs	Specify a threshold value using a real number greater than or equal to –1. Use –1 to ignore this threshold. If the average commit time in seconds exceeds this threshold, this Knowledge Script raises an event. The default value is –1.
Event severity when average commit time exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Heuristic completes threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of heuristic completes since the last sample exceeds this threshold, this Knowledge Script raises an event. The default value is –1.
Event severity when heuristic completes exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Transactions abandoned threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of transactions abandoned since the last sample exceeds this threshold, this Knowledge Script raises an event. The default value is 0.
Event severity when transactions abandoned exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.

77.71 TransCategRollBacks

Use this Knowledge Script to monitor the reasons why transactions were rolled back. This script reports this information on a per transaction category basis.

77.71.1 Versions of WebLogic Supported

8.1 SP6, 9.0, 9.1, 9.2, and 10.x

77.71.2 Resource Object

WebLogic Server

77.71.3 Default Schedule

The default interval for this Knowledge Script is Every 15 minutes.

77.71.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default value is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default value is n.
Timeouts threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of rollbacks due to timeouts since the last sample exceeds this threshold, this Knowledge Script raises an event. The default value is 0.
Event severity when timeouts exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Resource errors threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of rollbacks due to resource errors since the last sample exceeds this threshold, this Knowledge Script raises an event. The default value is 0.
Event severity when resource errors exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.

Description	How to Set It
Application errors threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of rollbacks due to application errors since the last sample exceeds this threshold, this Knowledge Script raises an event. The default value is 0.
Event severity when application errors exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
System errors threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of rollbacks due to system errors since the last sample exceeds this threshold, this Knowledge Script raises an event. The default value is 0.
Event severity when system errors exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.

77.72 TransResHealthState

Use this Knowledge Script to monitor the health state of the transactional resources of a WebLogic Server.

77.72.1 Versions of WebLogic Supported

8.1 SP6, 9.0, 9.1, 9.2, and 10.x

77.72.2 Resource Object

WebLogic Server

77.72.3 Default Schedule

The default interval for this Knowledge Script is Every 15 minutes.

77.72.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Collect data?	Set to **y** to collect data for reports and graphs. The default value is n.
Scale to 100?	Set to **y** to scale the values to 100. The default values range from 0-3, where 0 is `OK`, and 3 is `FAIL`. Setting to y will scale the values from 0-100, where 0 is `FAIL` and 100 is `OK`. The default value is n.
Event for health state of FAIL?	Set to **y** to raise an event if the health state is `FAIL`. The default value is y.
Event severity when health state is FAIL?	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 5.
Event for health state of CRITICAL?	Set to **y** to raise an event if the health state is `CRITICAL`. The default value is y.
Event severity when health state is CRITICAL	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 15.
Event for health state of WARNING?	Set to **y** to raise an event if the health state is `WARNING`. The default value is y.
Event severity when health state is WARNING	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Event for health state of OK?	Set to **y** to raise an event if the health state is `OK`. The default value is n.
Event severity when health state is OK	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 35.

77.73 TransResHeuristics

Use this Knowledge Script to monitor the reasons why transactions for transactional resources completed with an heuristic status. This script monitors the transactions that completed with a heuristic status for each of a WebLogic server's transactional resources. Transactions are rolled back when timeouts or application, system or resource errors occur.

77.73.1 Versions of WebLogic Supported

8.1 SP6, 9.0, 9.1, 9.2, and 10.x

77.73.2 Resource Object

WebLogic Server

77.73.3 Default Schedule

The default interval for this Knowledge Script is Every 15 minutes.

77.73.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default value is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default value is n.
Commits threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of heuristic commits since the last sample exceeds this threshold, this Knowledge Script raises an event. The default value is –1.
Event severity when commits exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Rollbacks threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of heuristic rollbacks the last sample exceeds this threshold, this Knowledge Script raises an event. The default value is 0.
Event severity when rollbacks exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.

Description	How to Set It
Mixed threshold	Specify a threshold value using an integer greater than or equal to −1. Use −1 to ignore this threshold. If the number of mixed heuristics since the last sample exceeds this threshold, this Knowledge Script raises an event. The default value is −1.
Event severity when mixed heuristics exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Hazards threshold	Specify a threshold value using an integer greater than or equal to −1. Use −1 to ignore this threshold. If the number of heuristic hazards since the last sample exceeds this threshold, this Knowledge Script raises an event. The default value is 0.
Event severity when hazards exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.

77.74 TransResources

Use this Knowledge Script to monitor statistics for transactional resources. This script monitors the transactions that have completed on a WebLogic server since the last sample on a per transactional resource basis. Transactions are rolled back when timeouts or application, system or resource errors occur.

77.74.1 Versions of WebLogic Supported

8.1 SP6, 9.0, 9.1, 9.2, and 10.x

77.74.2 Resource Object

WebLogic Server

77.74.3 Default Schedule

The default interval for this Knowledge Script is Every 15 minutes.

77.74.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default value is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default value is n.
Transactions completed threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of transactions completed since the last sample exceeds this threshold, this Knowledge Script raises an event. The default value is –1.
Event severity when transactions completed exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Transactions committed threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of transactions committed since the last sample exceeds this threshold, this Knowledge Script raises an event. The default value is –1.
Event severity when transactions committed exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.

Description	How to Set It
Transactions rolled back threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of transactions rolled back since the last sample exceeds this threshold, this Knowledge Script raises an event. The default value is 0.
Event severity when transactions rolled back exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Heuristic completes threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of heuristic completes since the last sample exceeds this threshold, this Knowledge Script raises an event. The default value is –1.
Event severity when heuristic completes exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.

77.75 WebAppSessions

Use this Knowledge Script to monitor Web applications. This script monitors the current number of sessions of a Web application and the number of sessions that have been run since the last sample.

77.75.1 Versions of WebLogic Supported

8.1 SP6, 9.0, 9.1, 9.2, and 10.x

77.75.2 Resource Object

WebLogic Server

77.75.3 Default Schedule

The default interval for this Knowledge Script is Every 15 minutes.

77.75.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default value is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default value is n.
Current sessions threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the current number of sessions of the Web Application exceeds the threshold, this Knowledge Script raises an event. The default value is –1.
Event severity when current sessions exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.
Peak sessions threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the peak number of concurrent sessions of the Web Application exceeds the threshold, this Knowledge Script raises an event. The default value is –1.
Event severity when peak sessions exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.

Description	How to Set It
Sessions run threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of sessions of the Web Application run since the last sample exceeds the threshold, this Knowledge Script raises an event. The default value is 0.
Event severity when sessions run exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default value is 25.

78 WebLogicSvr Knowledge Scripts

AppManager provides the following Knowledge Scripts for monitoring WebLogic Server.

From the Knowledge Script view of the Control Center Console, you can access more information about any Knowledge Script by selecting it and pressing **F1**. Or in the Operator Console, click any Knowledge Script in the Knowledge Script pane and press **F1**.

Knowledge Script	What It Does
Availability	Monitors the availability of a WebLogic Server.
HealthCheck	Verifies that a WebLogic Server is running, can respond to requests, and can accept connections from clients.
LogAccessLog	Returns the number of entries in the WebLogic Server's `access.log` since the last sample that match the search criteria. Provides a way to monitor HTTP requests and sessions.
LogAccessLogSetPath	Sets the absolute pathname for a Web server log file.
LogWebLogic	Monitors entries that are added to the log for a WebLogic Server.
LogWebLogicSetPath	Sets the absolute pathname for a WebLogic Server log file.
Memory	Monitors the physical and virtual memory use of a WebLogic Server.
SecurityUserLockout	Monitors statistics on the number of users locked out because invalid usernames and/or passwords were supplied at login.
ServerCPU	Returns WebLogic Server CPU utilization statistics.
ServerHealthState	Returns the health state of a WebLogic Server.
ServerJVMHeap	Returns statistics on the JVM Heap.
ServerRequests	Returns statistics on the requests received by the WebLogic Server.
ServerSecurity	Monitors statistics on the number of users locked out because invalid usernames and/or passwords were supplied at login.
ServerSockets	Monitors the number of open sockets on a WebLogic Server.
ServerState	Monitors the state (`RUNNING` or not) of a WebLogic Server as reported by the WebLogic Server.
ServerUptime	Monitors how many hours a WebLogic Server has been running.
StartAdminServer	Starts a specified WebLogic Server as the Administration Server for the domain.
StartServer	Starts a specified WebLogic Server as a Managed Server.
StopServer	Stops a specified WebLogic Server, which can be either an Administration Server or a Managed Server.

Managed Server/Cluster Knowledge Scripts

The following Knowledge Scripts are focused on managed servers, the Node Manager, and clusters.

Knowledge Script	What It Does
ClusterMessage	Monitors a server's view of the members of a WebLogic cluster.
StartServerNodeMgr	Starts a WebLogic Server as a Managed Server using the Node Manager.

JDBC Connection Pool Knowledge Scripts

The following Knowledge Scripts are focused on JDBC connection pools:

Knowledge Script	What It Does
JDBCAvailableConnections	Monitors the available number of connections in a JDBC Connection Pool.
JDBCClients	Monitors statistics on the clients of a JDBC Connection Pool.
JDBCConnectionCapacity	Monitors the current and maximum capacity of a JDBC Connection Pool.
JDBCConnections	Monitors statistics on the connections in a JDBC Connection Pool.

Java Message System (JMS) Knowledge Scripts

The following Knowledge Scripts are focused on the JMS subsystem of a WebLogic Server:

Knowledge Script	What It Does
JMS	Monitors the number of JMS Connections in use and the number of JMS servers deployed by a WebLogic Server.
JMSConnectionsSessions	Returns statistics on the number of sessions for JMS connections.
JMSHealthState	Returns the health state of the JMS subsystem of a WebLogic Server.
JMSServersBytesStored	Returns statistics on the number of bytes stored for the JMS servers.
JMSServersDestinations	Returns statistics on the number of destinations instantiated on the JMS servers.
JMSServersHealthState	Returns the health state of the JMS Servers of a WebLogic Server.
JMSServersMsgsStored	Returns statistics on messages for the JMS servers.
JMSServersSessionPools	Returns statistics on the session pools instantiated on the JMS servers.

Java Virtual Machine (JVM) Knowledge Scripts

The following Knowledge Scripts are focused on the JVM:

Knowledge Script	What It Does
JRockitGC	Returns statistics on the last time garbage collection was executed in the server and the total amount of time spent in garbage collection.
JRockitThreads	Returns statistics on the number of daemon threads and the total number of threads within the WebLogic Server.

Java Transaction API (JTA) Knowledge Scripts

The following Knowledge Scripts are focused on the JTA subsystem of a WebLogic Server:

Knowledge Script	What It Does
JTAActiveTrans	Monitors the current number of transactions in progress on a WebLogic Server.
JTACompletedTrans	Monitors the transactions that have completed on a WebLogic Server since the last sample.
JTAHealthState	Returns the health state of the JTA subsystem of a WebLogic Server.
JTATransRolledBack	Provides statistics on the causes for transaction rollbacks.
TransResources	Returns statistics for the transactional resources of a WebLogic Server.
TransResHealthState	Returns the health state of the transactional resources of a WebLogic Server.
TransResHeuristics	Provides a breakdown of the reasons for heuristic completes for the transactional resources of a WebLogic Server.
TransCateg	Returns statistics for the transaction categories of a WebLogic Server.
TransCategRollBacks	Provides statistics on the reasons why transactions were rolled back for the transaction categories of a WebLogic Server.

EJB Knowledge Scripts

The following Knowledge Scripts are focused on the EJBs on a WebLogic Server:

Knowledge Script	What It Does
EntityEJBCache	Returns statistics on caching for an Entity EJB.
EntityEJBError	Returns statistics on errors generated by an Entity EJB.
EntityEJBPool	Returns the percentage of beans that are idle and in-use for an Entity EJB.
EntityEJBTrans	Returns statistics on transactions for an Entity EJB.
EntityEJBWait	Returns the number of times a client has waited for an Entity EJB and the number of times that clients have timed out waiting for an Entity EJB.

Knowledge Script	What It Does
MsgDrivenEJBError	Monitors errors generated by a message-driven EJB.
MsgDrivenEJBPool	Monitors the number of message-driven EJBs that are in use and the number that are idle.
MsgDrivenEJBTrans	Returns statistics on transactions for a message-driven EJB.
MsgDrivenEJBWait	Returns the number of times a client has waited for a message-driven EJB and the number of times that clients have timed out waiting for a message-driven EJB.
StatefulEJBCache	Returns statistics on the cache for a Stateful EJB.
StatefulEJBTrans	Returns statistics on transactions for a Stateful EJB.
StatefulEJBWait	Returns the number of times a client waited for a bean and the number of times that clients have timed out waiting for a bean for the Stateful EJB.
StatelessEJBError	Monitors errors generated by a Stateless EJB.
StatelessEJBPool	Returns the number and percentage of beans that are idle and in use for a Stateless EJB.
StatelessEJBTrans	Returns statistics on transactions for a Stateless EJB.
StatelessEJBWait	Returns the number of times a client waited for a bean and the number of times that clients have timed out waiting for a bean for the Stateless EJB.

Web Applications and Servlets Knowledge Scripts

The following Knowledge Scripts are focused on the Web applications and servlets on a WebLogic Server:

Knowledge Script	What It Does
ServletExecTime	Monitors the execution times and number of times that the servlets of a Web application were invoked.
WebAppSessions	Monitors the current number of sessions of a Web application and the number of sessions that have been run since the last sample.

Connector Connections Knowledge Scripts

The following Knowledge Scripts are focused on the Connector connections of a WebLogic Server:

Knowledge Script	What It Does
ConnectorConnCurrent	Monitors statistics on the current number of active and free Connector connections.
ConnectorConnRequests	Returns the number of Connector connections created, destroyed, matched, rejected and recycled since the last sample.

Data-Gathering Knowledge Script

The following Knowledge Script is used to start or stop components that gather data for the Knowledge Scripts:

Knowledge Script	What It Does
NetIQAgent	Starts or stops the NetIQ agent that helps gather data about WebLogic Servers and their components.

SQL Profiling and Monitoring Knowledge Script

The following Knowledge Script monitors individual SQL statements:

Knowledge Script	What It Does
JDBCEnableSQLProfiling	Enables or disables profiling of SQL statements.

WebLogic Server Report Knowledge Scripts

The following Knowledge Scripts are used to generate reports:

Knowledge Script	What It Does
Report_HealthSummary	Generates a report summarizing the health of monitored WebLogic servers.
Report_PerfSummary	Generates a report summarizing the performance of monitored WebLogic servers.

78.1 Availability

Use this Knowledge Script to monitor availability of a WebLogic Server. This script verifies that a WebLogic Server is running and can accept requests.

78.1.1 Versions of WebLogic Supported

9.0, 9.1, and 9.2

78.1.2 Resource Object

WebLogic Server

78.1.3 Default Schedule

The default interval for this script is Every 15 minutes.

78.1.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default is n.
Event severity when WebLogic Server is not responding?	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 10.

78.2 ClusterMessage

Use this Knowledge Script to monitor a server's view of the members of a WebLogic cluster. This script reports statistics on the multicast message and fragments sent and received by a WebLogic server.

78.2.1 Versions of WebLogic Supported

9.0, 9.1, and 9.2

78.2.2 Resource Object

WebLogic Server

78.2.3 Default Schedule

The default interval for this script is Every 15 minutes.

78.2.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default is n.
Fragments sent threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of fragments sent since the last sample exceeds this threshold, an event is raised. The default is –1.
Event severity when fragments sent exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Fragments received threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of fragments received since the last sample exceeds this threshold, an event is raised. The default is –1.
Event severity when fragments received exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Resend requests threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of requests to resend a message since the last sample exceeds this threshold, an event is raised. The default is –1.
Event severity when resend requests exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.

Description	How to Set It
Messages lost threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of incoming messages lost since the last sample exceeds this threshold, an event is raised. The default is -1.
Event severity when messages lost exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Foreign fragments dropped threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of fragments received from a foreign domain or foreign cluster since the last sample exceeds this threshold, an event is raised. The default is 0.
Event severity when foreign fragments dropped exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.

78.3 ConnectorConnCurrent

Use this Knowledge Script to monitor the number of active and free connections in a Connector Connection Pool. These statistics provide a view of the Connector Connection Pool from the server's perspective, which will help determine if the capacity of the pool is large enough.

78.3.1 Versions of WebLogic Supported

9.0, 9.1, and 9.2

78.3.2 Resource Object

WebLogic Server

78.3.3 Default Schedule

The default interval for this script is Every 15 minutes.

78.3.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default is n.
Active connections threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the current number of active connections exceeds this threshold, an event is raised. The default is –1.
Event severity when active connections exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Peak active connections threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the peak number of active connections exceeds this threshold, an event is raised. The default is –1.
Event severity when peak active connections exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Average active connections threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the average number of active connections exceeds this threshold, an event is raised. The default is –1.
Event severity when average active connections exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.

Description	How to Set It
Free connections threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the current number of free connections exceeds this threshold, an event is raised. The default is –1.
Event severity when free connections exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Peak free connections threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the peak number of free connections exceeds this threshold, an event is raised. The default is –1.
Event severity when peak free connections exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Percent of connections in use threshold	Specify a threshold value using an integer greater than or equal to –1 and less than or equal to 100. Use –1 to ignore this threshold. If the percent of connections in use exceeds this threshold, an event is raised. The default is –1.
Event severity when percent of connections in use exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.

78.4 ConnectorConnRequests

Use this Knowledge Script to monitor the rate at which a Connector Connection Pool is servicing requests for connections. These statistics provide a view of the Connector Connection Pool from the clients' perspective, which can help determine if the capacity of the pool is large enough.

78.4.1 Versions of WebLogic Supported

9.0, 9.1, and 9.2

78.4.2 Resource Object

WebLogic Server

78.4.3 Default Schedule

The default interval for this script is Every 15 minutes.

78.4.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default is n.
Connections created threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of connections created since the last sample exceeds this threshold, an event is raised. The default is –1.
Event severity when connections created exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Connections destroyed threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of connections destroyed since the last sample exceeds this threshold, an event is raised. The default is –1.
Event severity when connections destroyed exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Connections matched threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of times since the last sample that a request for a connection was satisfied via an existing connection exceeds this threshold, an event is raised. The default is 0.
Event severity when connections matched exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.

Description	How to Set It
Connections rejected threshold	Specify a threshold value using an integer greater than or equal to −1. Use −1 to ignore this threshold. If the number of times since the last sample that a request for a connection was rejected exceeds this threshold, an event is raised. The default is −1.
Event severity when connections rejected exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Connections recycled threshold	Specify a threshold value using an integer greater than or equal to −1. Use −1 to ignore this threshold. If the number of connections that have been recycled since the last sample exceeds this threshold, an event is raised. The default is −1.
Event severity when connections recycled exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Connections leaked threshold	Specify a threshold value using an integer greater than or equal to −1. Use −1 to ignore this threshold. If the number of leaked connections since the last sample exceeds this threshold, an event is raised. The default is 0.
Event severity when leaked connections exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.

78.5 EntityEJBCache

Use this Knowledge Script to monitor statistics for an Entity EJB. This script reports caching statistics for an Entity EJB.

This script may be used to determine a cache hit ratio and how frequently instances of the Entity EJB are being activated and passivated. These values will help determine if the size of the cache is appropriate.

78.5.1 Versions of WebLogic Supported

9.0, 9.1, and 9.2

78.5.2 Resource Object

WebLogic Server

78.5.3 Default Schedule

The default interval for this script is Every 15 minutes.

78.5.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default is n.
Current beans threshold	Specify a threshold value using an integer value greater than or equal to –1. Use –1 to ignore this threshold. If the number of beans currently in use exceeds this threshold, an event is raised. The default is –1.
Event severity when current beans exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Cache accesses threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of cache accesses since the last sample exceeds this threshold, an event is raised. The default is –1.
Event severity when cache accesses exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Cache hit ratio threshold	Specify a threshold value using a real number greater than or equal to –1. Use –1 to ignore this threshold. If the cache hit ratio (expressed as a percentage) since the last sample falls below this threshold, an event is raised. The default is –1.
Event severity when cache hit ratio falls below threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.

Description	How to Set It
Activations threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of activations since the last sample exceeds this threshold, an event is raised. The default is –1.
Event severity when activations exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Passivations threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of passivations since the last sample exceeds this threshold, an event is raised. The default is –1.
Event severity when passivations exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Cache miss count threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the cache miss count since the last sample exceeds this threshold, an event is raised. The default is –1.
Event severity when cache miss count exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.

78.6 EntityEJBError

Use this Knowledge Script to monitor errors generated by an Entity EJB. This script reports error statistics for an Entity EJB.

This script may be used to determine the number of times the Entity EJB was destroyed due to an exception, and the number of failed attempts to retrieve an EJB from the pool. These values will help monitor the Entity EJB if errors occur.

78.6.1 Versions of WebLogic Supported

9.0, 9.1, and 9.2

78.6.2 Resource Object

WebLogic Server

78.6.3 Default Schedule

The default interval for this script is Every 15 minutes.

78.6.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default is n.
Destroyed bean instances threshold	Specify a threshold value using an integer value greater than or equal to –1. Use –1 to ignore this threshold. If the number of times since the last sample that a bean instance was destroyed due to a thrown exception exceeds this threshold, an event is raised. The default is 0.
Event severity when destroyed bean instances exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Miss count threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of failed attempts to retrieve a bean from the free pool since the last sample exceeds this threshold, an event is raised. The default is 0.
Event severity when miss count exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.

78.7 EntityEJBPool

Use this Knowledge Script to monitor for the number or percentage of in-use and idle beans in an Entity EJB pool. These values will help determine if the size of the pool has been set properly.

78.7.1 Versions of WebLogic Supported

9.0, 9.1, and 9.2

78.7.2 Resource Object

WebLogic Server

78.7.3 Default Schedule

The default interval for this script is Every 15 minutes.

78.7.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default is n.
Beans idle threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of beans that are allocated but idle exceeds this threshold, an event is raised. The default is –1.
Event severity when beans idle exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Beans in use threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of beans in use exceeds this threshold, an event is raised. The default is –1.
Event severity when beans in use exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Percent of pool in use threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the percentage of available beans in the pool that are in use exceeds this threshold, an event is raised. The default is –1.
Event severity when percent of pool in use exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.

78.8 EntityEJBTrans

Use this Knowledge Script to monitor the transaction rates for an Entity EJB. Transactions are rolled back when timeouts or application, system or resource errors occur. The JTATransRolledBack Knowledge Script provides a breakdown of the reasons for rollbacks.

78.8.1 Versions of WebLogic Supported

9.0, 9.1, and 9.2

78.8.2 Resource Object

WebLogic Server

78.8.3 Default Schedule

The default interval for this script is Every 15 minutes.

78.8.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default is n.
Transactions committed threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of transactions committed since the last sample exceeds this threshold, an event is raised. The default is –1.
Event severity when transactions committed exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Transactions rolled back threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of transactions rolled back since the last sample exceeds this threshold, an event is raised. The default is 0.
Event severity when transactions rolled back exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Transactions timed out threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of transactions timed out since the last sample exceeds this threshold, an event is raised. The default is 0.
Event severity when transactions timed out exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.

78.9 EntityEJBWait

Use this Knowledge Script to monitor the number of times a request had to wait for an EJB and the number of times a request timed out waiting for an EJB. Increasing the cache size may help reduce the number of timeouts.

78.9.1 Versions of WebLogic Supported

9.0, 9.1, and 9.2

78.9.2 Resource Object

WebLogic Server

78.9.3 Default Schedule

The default interval for this script is Every 15 minutes.

78.9.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default is n.
Times waited threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of times since the last sample that clients have waited for a bean exceeds this threshold, an event is raised. The default is –1.
Event severity when times waited exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Timeouts threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of timeouts since the last sample exceeds this threshold, an event is raised. The default is 0.
Event severity when timeouts exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.

78.10 HealthCheck

Use this Knowledge Script to make sure a WebLogic Server is running and is able to service requests. This script performs the following checks:

- Verifies the WebLogic Server is running.
- Verifies the WebLogic Server is able to respond to a request.
- Verifies the WebLogic Server is able to accept connections from clients.

This script may also be used to:

- Restart the WebLogic Server if the script determines it is not running.
- Set response time thresholds for responding to requests and establishing connections.
- Raise events (with user-defined severity levels) if the WebLogic Server is not running, is unable to respond to a request, or is unable to accept connections.

If this script detects that the WebLogic Server is not running, it raises a general event to alert you to the condition but it does not perform additional tests for responding to a request and accepting a connection from a client. Therefore, if the WebLogic Server is not running, the script does not return data or compare the thresholds for the **WebLogic Ping time** and the **Average connection time**, and does not raise events to indicate that a WebLogic Ping or connectivity test failed.

If a WebLogic Server is running but is not able to respond to a request, an event is raised to indicate the ping request failed, but the script does not return data or compare the thresholds for the **WebLogic Ping time**. Similarly, if a WebLogic Server is running, but is not able to accept a connection from a client, an event is raised to indicate that the connectivity test failed, but the script does not return data or compare the thresholds for the **Average connection time**.

78.10.1 Versions of WebLogic Supported

9.0, 9.1, and 9.2

78.10.2 Resource Object

WebLogic Server

78.10.3 Default Schedule

The default interval for this script is Every 15 minutes.

78.10.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default is y.

Description	How to Set It
Collect data?	Set to **y** to collect data for reports and graphs. The default is n.
Event severity when server is not running	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 10.
Restart WebLogic Server if not running?	Set to **y** to restart the WebLogic server if it is not running. The default is n.
Use Node Manager to restart server?	Set to **y** to restart the WebLogic server using Node Manager. The default is n.
Start Command	Set to the name of the script file that you use to start a WebLogic Server, including any parameters that the script requires. The name of the script must include the complete path for the file.
Start Command Parameters	Specify conditions to apply to the Start Command parameter.
Pass name of server, IP address, port, admin username and password to Start Script?	Set to **y** to pass these parameters to the Start Script. These parameters will be added to the end of the string supplied for Start Script. The default is n.
Start time limit	Set to the number of seconds within which the WebLogic Server should complete initialization. The default is 300.
Requests	Set to the number of requests, between 1 and 10, that should be made to the server to determine if it is able to respond to requests. The default is 3.
WebLogic Ping time threshold in secs	Specify a threshold value using a real number greater than or equal to –1. Use –1 to ignore this threshold. If the WebLogic Ping time in seconds exceeds this threshold, an event is raised. The default is 0.
Event severity when WebLogic Ping response not received	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 10.
Event severity when WebLogic Ping time exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Connections	Set to the number of connections, between 1 and 10, that should be made to the server to determine if it is able to accept connections from clients. The default is 3.
Average connection time threshold in secs	Specify a threshold value using a real number greater than or equal to –1. Use –1 to ignore this threshold. If the average time in seconds it took the server to establish a connection exceeds this threshold, an event is raised. The default is 0.
Event severity when connection not established	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 10.
Event severity when connection time exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.

78.11 JDBCAvailableConnections

Use this Knowledge Script to monitor the available number of connections in a JDBC Connection Pool. This script reports the number of available and unavailable connections for a JDBC Connection Pool.

This script may be used to monitor the number available and unavailable connections in a JDBC Connection Pool, and the peak number of available and unavailable connections in a JDBC Connection Pool. These values will help determine if the JDBC Connection Pool is over-utilized or under-utilized.

78.11.1 Versions of WebLogic Supported

9.0, 9.1, and 9.2

78.11.2 Resource Object

WebLogic Server

78.11.3 Default Schedule

The default interval for this script is Every 15 minutes.

78.11.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default is n.
Available connections threshold	Specify a threshold value using an integer value greater than or equal to –1. Use –1 to ignore this threshold. If the number of available connections exceeds this threshold, an event is raised. The default is –1.
Event severity when available connections exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Peak number of available connections threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the peak number of available connections exceeds this threshold, an event is raised. The default is –1.
Event severity when peak number of available connections exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Unavailable connections threshold	Specify a threshold value using an integer value greater than or equal to –1. Use –1 to ignore this threshold. If the number of unavailable connections exceeds this threshold, an event is raised. The default is –1.

Description	How to Set It
Event severity when unavailable connections exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Peak number of unavailable connections threshold	Specify a threshold value using an integer greater than or equal to −1. Use −1 to ignore this threshold. If the peak number of unavailable connections exceeds this threshold, an event is raised. The default is −1.
Event severity when peak number of unavailable connections exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.

78.12 JDBCClients

Use this Knowledge Script to monitor the number of requests that had to wait for a JDBC Connection and how long it took for a request to get a connection. If these values are consistently high, consider increasing the size of the pool.

This script may be used to measure how quickly and efficiently the JDBC Connection Pool is servicing clients' requests and will help determine if the capacity of the pool is sufficient.

78.12.1 Versions of WebLogic Supported

9.0, 9.1, and 9.2

78.12.2 Resource Object

WebLogic Server

78.12.3 Default Schedule

The default interval for this script is Every 15 minutes.

78.12.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default is n.
Clients waiting threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of clients waiting for a JDBC connection exceeds this threshold, an event is raised. The default is –1.
Event severity when clients waiting exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Peak clients waiting threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the peak number of clients waiting for a JDBC connection exceeds this threshold, an event is raised. The default is 0.
Event severity when peak clients waiting exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Peak wait time threshold in secs	Specify a threshold value using a real number greater than or equal to –1. Use –1 to ignore this threshold. If the longest time (in seconds) that a client waited for a JDBC connection exceeds this threshold, an event is raised. The default is –1.

Description	How to Set It
Event severity when peak wait time exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Average connection delay time threshold in secs	Specify a threshold value using a real number greater than or equal to −1. Use −1 to ignore this threshold. If the average time (in seconds) that a client waited for a JDBC connection exceeds this threshold, an event is raised. The default is −1.
Event severity when average connection delay time exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.

78.13 JDBCConnections

Use this Knowledge Script to monitor a JDBC Connection Pool. This script reports the number of active connections in the JDBC Connection Pool and will indicate whether the capacity of the pool needs adjustment.

78.13.1 Versions of WebLogic Supported

9.0, 9.1, and 9.2

78.13.2 Resource Object

WebLogic Server

78.13.3 Default Schedule

The default interval for this script is Every 15 minutes.

78.13.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default is n.
Active connections threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of active connections exceeds this threshold, an event is raised. The default is –1.
Event severity when active connections exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Total connections threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the total number of connections exceeds this threshold, an event is raised. The default is –1.
Event severity when total connections exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Peak active connections threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the peak number of active connections exceeds this threshold, an event is raised. The default is –1.
Event severity when peak active connections exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.

Description	How to Set It
Percent of connections in use threshold	Specify a threshold value using an integer greater than or equal to –1 and less than or equal to 100. Use –1 to ignore this threshold. If the percent of connections in use exceeds this threshold, an event is raised. The default is -1.
Event severity when percent of connections in use exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Leaked connections threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of leaked connections since the last sample exceeds this threshold, an event is raised. The default is 0.
Event severity when leaked connections exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Refresh failures threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of refresh failures since the last sample exceeds this threshold, an event is raised. The default is 0.
Event severity when refresh failures exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Average active connections threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the average number of active connections exceeds this threshold, an event is raised. The default is –1.
Event severity when average active connections exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.

78.14 JDBCConnectionCapacity

Use this Knowledge Script to monitor the current and maximum capacity of a JDBC Connection Pool. These values will help determine if the JDBC Connection Pool is too large or too small.

78.14.1 Versions of WebLogic Supported

9.0, 9.1, and 9.2

78.14.2 Resource Object

WebLogic Server

78.14.3 Default Schedule

The default interval for this script is Every 15 minutes.

78.14.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default is n.
Current capacity threshold	Specify a threshold value using an integer value greater than or equal to –1. Use –1 to ignore this threshold. If the current capacity exceeds this threshold, an event is raised. The default is –1.
Event severity when current capacity exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Maximum capacity threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the maximum capacity exceeds this threshold, an event is raised. The default is –1.
Event severity when maximum capacity exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.

78.15 JDBCEnableSQLProfiling

Use this Knowledge Script to enable or disable profiling of SQL statements. This script provides a way to enable or disable SQL statement profiling without using the Administrator Console.

78.15.1 Versions of WebLogic Supported

9.0, 9.1, and 9.2

78.15.2 Resource Object

WebLogic Server

78.15.3 Default Schedule

The default interval for this script is Run once.

78.15.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default is y.
Enable SQL statement profiling	Set to **y** to enable SQL statement profiling within the WebLogic Server. The default is y.

78.16 JMS

Use this Knowledge Script to monitor the Java Message System (JMS). This script monitors the number of JMS Connections in use and the number of JMS servers deployed by a WebLogic Server.

78.16.1 Versions of WebLogic Supported

9.0, 9.1, and 9.2

78.16.2 Resource Object

WebLogic Server

78.16.3 Default Schedule

The default interval for this script is Every 15 minutes.

78.16.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default is n.
Current connections threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the current number of JMS Connections exceeds this threshold, an event is raised. The default is –1.
Event severity when current connections exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Peak connections threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the peak number of JMS Connections exceeds this threshold, an event is raised. The default is –1.
Event severity when peak connections exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Connections made threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of JMS Connections made to this WebLogic Server since the last sample exceeds this threshold, an event is raised. The default is –1.
Event severity when connections made exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Current servers threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the current number of deployed JMS Servers exceeds this threshold, an event is raised. The default is –1.

Description	How to Set It
Event severity when current servers exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Peak servers threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the peak number of deployed JMS Servers exceeds this threshold, an event is raised. The default is –1.
Event severity when peak servers exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Servers deployed threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of JMS Servers deployed since the last sample exceeds this threshold, an event is raised. The default is –1.
Event severity when servers deployed exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.

78.17 JMSConnectionsSessions

Use this Knowledge Script to monitor JMS connections. This script monitors the number of sessions in use for each JMS Connection and the rate at which sessions are being opened.

78.17.1 Versions of WebLogic Supported

9.0, 9.1, and 9.2

78.17.2 Resource Object

WebLogic Server

78.17.3 Default Schedule

The default interval for this script is Every 15 minutes.

78.17.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default is n.
Current sessions threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the current number of sessions for the JMS Connection exceeds this threshold, an event is raised. The default is –1.
Event severity when current sessions exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Peak sessions threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the peak number of sessions for the JMS Connection exceeds this threshold, an event is raised. The default is –1.
Event severity when peak sessions exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Sessions opened threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of sessions opened for the JMS Connection since the last sample exceeds this threshold, an event is raised. The default is –1.
Event severity when sessions opened exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.

78.18 JMSHealthState

Use this Knowledge Script to monitor the health state of the JMS subsystem of a WebLogic Server.

78.18.1 Versions of WebLogic Supported

9.0, 9.1, and 9.2

78.18.2 Resource Object

WebLogic Server

78.18.3 Default Schedule

The default interval for this script is Every 15 minutes.

78.18.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Collect data?	Set to **y** to collect data for reports and graphs. The default is n.
Scale to 100?	Set to **y** to scale the values to 100. The default values range from 0-3, where 0 is `OK`, and 3 is `FAIL`. Setting to y will scale the values from 0-100, where 0 is `FAIL` and 100 is `OK`. The default is n.
Event for health state of FAIL?	Set to **y** to raise an event if the health state is `FAIL`. The default is y.
Event severity when health state is FAIL?	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 5.
Event for health state of CRITICAL?	Set to **y** to raise an event if the health state is `CRITICAL`. The default is y.
Event severity when health state is CRITICAL	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 15.
Event for health state of WARNING?	Set to **y** to raise an event if the health state is `WARNING`. The default is y.
Event severity when health state is WARNING	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Event for health state of OK?	Set to **y** to raise an event if the health state is `OK`. The default is n.
Event severity when health state is OK	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 35.

78.19 JMSServersBytesStored

Use this Knowledge Script to monitor JMS servers. This script monitors the number of bytes consumed by messages on each JMS server.

The **Time in threshold condition** parameter is the time (in seconds) that the current number of bytes consumed exceeds a WebLogic Server threshold for that JMS server. This value, along with the current number of bytes, can help you adjust the maximum bytes for the JMS server.

78.19.1 Versions of WebLogic Supported

9.0, 9.1, and 9.2

78.19.2 Resource Object

WebLogic Server

78.19.3 Default Schedule

The default interval for this script is Every 15 minutes.

78.19.4 Setting Parameter values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default is n.
Current bytes threshold	Specify a threshold value using a real number greater than or equal to –1. Use –1 to ignore this threshold. If the current number of bytes stored on this JMS Server exceeds this threshold, an event is raised. The default is –1.
Event severity when current bytes exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Pending bytes threshold	Specify a threshold value using a real number greater than or equal to –1. Use –1 to ignore this threshold. If the current number of pending bytes stored on this JMS server exceeds this threshold, an event is raised. The default is –1.
Event severity when pending bytes exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Peak bytes threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the peak number of bytes stored on this JMS Server exceeds this threshold, an event is raised. The default is –1.

Description	How to Set It
Event severity when peak bytes exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Time in threshold condition threshold	Specify a threshold value using a real number greater than or equal to –1. Use –1 to ignore this threshold. If the number of seconds spent in the threshold condition (due to the number of bytes stored on this JMS Server) since the last sample exceeds this threshold, an event is raised. The default is 0.
Event severity when time in threshold condition exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.

78.20 JMSServersDestinations

Use this Knowledge Script to monitor JMS servers. This script monitors the current number of destinations for each JMS server and the rate at which those destinations are being created.

78.20.1 Versions of WebLogic Supported

9.0, 9.1, and 9.2

78.20.2 Resource Object

WebLogic Server

78.20.3 Default Schedule

The default interval for this script is Every 15 minutes.

78.20.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default is n.
Current destinations threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the current number of destinations for this JMS server exceeds this threshold, an event is raised. The default is –1.
Event severity when current destinations exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Peak destinations threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the peak number of destinations for this JMS server exceeds this threshold, an event is raised. The default is –1.
Event severity when peak destinations exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Destinations instantiated threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of destinations instantiated on this JMS server since the last sample exceeds this threshold, an event is raised. The default is –1.
Event severity when destinations instantiated exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.

78.21 JMSServersHealthState

Use this Knowledge Script to monitor the health state of the JMS servers of a WebLogic Server.

78.21.1 Versions of WebLogic Supported

9.0, 9.1, and 9.2

78.21.2 Resource Object

WebLogic Server

78.21.3 Default Schedule

The default interval for this script is Every 15 minutes.

78.21.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Collect data?	Set to **y** to collect data for reports and graphs. The default is n.
Scale to 100?	Set to y to scale the values to 100. The default values range from 0-3, where 0 is `OK`, and 3 is `FAIL`. Setting to y will scale the values from 0-100, where 0 is `FAIL` and 100 is `OK`. The default is n.
Event for health state of FAIL?	Set to **y** to raise an event if the health state is `FAIL`. The default is y.
Event severity when health state is FAIL?	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 5.
Event for health state of CRITICAL?	Set to **y** to raise an event if the health state is `CRITICAL`. The default is y.
Event severity when health state is CRITICAL	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 15.
Event for health state of WARNING?	Set to **y** to raise an event if the health state is `WARNING`. The default is y.
Event severity when health state is WARNING	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Event for health state of OK?	Set to **y** to raise an event if the health state is `OK`. The default is n.
Event severity when health state is OK	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 35.

78.22 JMSServersMsgsStored

Use this Knowledge Script to monitor JMS servers. This script monitors the number of messages on each JMS server. The time in threshold condition is the number of seconds in which the current number of messages is above or below a WebLogic Server threshold for that JMS server. This value, along with the current number of messages, can help you adjust the maximum messages for the JMS server.

78.22.1 Versions of WebLogic Supported

9.0, 9.1, and 9.2

78.22.2 Resource Object

WebLogic Server

78.22.3 Default Schedule

The default interval for this script is Every 15 minutes.

78.22.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default is n.
Current messages threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the current number of messages stored on this JMS server, not including pending messages, exceeds this threshold, an event is raised. The default is –1.
Event severity when current messages exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Pending messages threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the current number of pending messages (unacknowledged or uncommitted) stored on this JMS server exceeds this threshold, an event is raised. The default is –1.
Event severity when pending messages exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Peak messages threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the peak number of messages stored on this JMS Server exceeds this threshold, an event is raised. The default is –1.

Description	How to Set It
Event severity when peak messages exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Time in threshold condition threshold in secs	Specify a threshold value using a real number greater than or equal to –1. Use –1 to ignore this threshold. If the number of seconds time spent in the threshold condition (due to the number of messages stored on this JMS server) exceeds this threshold, an event is raised. The default is 0.
Event severity when time in threshold condition exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.

78.23 JMSServersSessionPools

Use this Knowledge Script to monitor JMS servers. This script monitors the number of session pools in use by each JMS server and the rate at which those pools are being created.

78.23.1 Versions of WebLogic Supported

9.0, 9.1, and 9.2

78.23.2 Resource Object

WebLogic Server

78.23.3 Default Schedule

The default interval for this script is Every 15 minutes.

78.23.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default is n.
Current session pools threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the current number of session pools instantiated on this JMS server exceeds this threshold, an event is raised. The default is –1.
Event severity when current session pools exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Peak session pools threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the peak number of session pools instantiated on this JMS server exceeds this threshold, an event is raised. The default is –1.
Event severity when peak session pools exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Session pools instantiated threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of session pools instantiated on this JMS server since the last sample exceeds this threshold, an event is raised. The default is –1.
Event severity when session pools instantiated bytes exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.

78.24 JRockitGC

Use this Knowledge Script to monitor the last time garbage collection was executed in the server and the total amount of time spent in garbage collection. These values will help determine potential bottlenecks within the WebLogic Server instance.

78.24.1 Versions of WebLogic Supported

9.0, 9.1, and 9.2

78.24.2 Resource Object

WebLogic Server

78.24.3 Default Schedule

The default interval for this script is Every 15 minutes.

78.24.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default is n.
Seconds since last garbage collection ended threshold	Specify a threshold value using an integer value greater than or equal to –1. Use –1 to ignore this threshold. If the number of seconds since the last garbage collection run exceeds this threshold, an event is raised. The default is –1.
Event severity when seconds since last garbage collection exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Number of garbage collection runs threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of garbage collection runs since the last sample exceeds this threshold, an event is raised. The default is –1.
Event severity when number of garbage collection runs exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Average garbage collection time threshold in secs	Specify a threshold value using an integer value greater than or equal to –1. Use –1 to ignore this threshold. If the average time spent in a garbage collection run in seconds since the last sample exceeds this threshold, an event is raised. The default is 0.
Event severity when average garbage collection time exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.

78.25 JRockitThreads

Use this Knowledge Script to monitor the number of daemon threads and the total number of threads within the WebLogic Server. These values will help determine potential bottlenecks within the WebLogic Server instance.

78.25.1 Versions of WebLogic Supported

9.0, 9.1, and 9.2

78.25.2 Resource Object

WebLogic Server

78.25.3 Default Schedule

The default interval for this script is Every 15 minutes.

78.25.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default is n.
Number of daemon threads threshold	Specify a threshold value using an integer value greater than or equal to –1. Use –1 to ignore this threshold. If the number of daemon threads exceeds this threshold, an event is raised. The default is –1.
Event severity when number of daemon threads exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Total number of threads threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the total number of threads exceeds this threshold, an event is raised. The default is –1.
Event severity when total number of threads exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.

78.26 JTAActiveTrans

Use this Knowledge Script to monitor the current number of transactions in progress on a WebLogic Server.

78.26.1 Versions of WebLogic Supported

9.0, 9.1, and 9.2

78.26.2 Resource Object

WebLogic Server

78.26.3 Default Schedule

The default interval for this script is Every 15 minutes.

78.26.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default is n.
Active transactions threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of active transactions exceeds this threshold, an event is raised. The default is –1.
Event severity when active transactions exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.

78.27 JTACompletedTrans

Use this Knowledge Script to monitor the Java Transaction API (JTA). This script monitors the transactions that have completed on a WebLogic Server since the last sample. Transactions are rolled back when timeouts or application, system or resource errors occur. The JTATransRolledBack script provides a breakdown of the reasons for rollbacks.

78.27.1 Versions of WebLogic Supported

9.0, 9.1, and 9.2

78.27.2 Resource Object

WebLogic Server

78.27.3 Default Schedule

The default interval for this script is Every 15 minutes.

78.27.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default is n.
Total transactions threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the total number of transactions since the last sample exceeds this threshold, an event is raised. The default is –1.
Event severity when total transactions exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Transactions committed threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of transactions committed since the last sample exceeds this threshold, an event is raised. The default is –1.
Event severity when transactions committed exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Transactions rolled back threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of transactions rolled back since the last sample exceeds this threshold, an event is raised. The default is 0.
Event severity when transactions rolled back exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.

Description	How to Set It
Heuristic completes threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of transactions with heuristic completes since the last sample exceeds this threshold, an event is raised. The default is –1.
Event severity when heuristic completes exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Average commit time threshold	Specify a threshold value using a real number greater than or equal to –1. Use –1 to ignore this threshold. If the average commit time in seconds exceeds this threshold, an event is raised. The default is –1.
Event severity when average commit time exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Transactions abandoned threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of transactions abandoned since the last sample exceeds this threshold, an event is raised. The default is -1.
Event severity when transactions abandoned exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.

78.28 JTAHealthState

Use this Knowledge Script to monitor the health state of the JTA subsystem of a WebLogic Server.

78.28.1 Versions of WebLogic Supported

9.0, 9.1, and 9.2

78.28.2 Resource Object

WebLogic Server

78.28.3 Default Schedule

The default interval for this script is Every 15 minutes.

78.28.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Collect data?	Set to **y** to collect data for reports and graphs. The default is n.
Scale to 100?	Set to **y** to scale the values to 100. The default values range from 0-3, where 0 is `OK`, and 3 is `FAIL`. Setting to y will scale the values from 0-100, where 0 is `FAIL` and 100 is `OK`. The default is n.
Event for health state of FAIL?	Set to **y** to raise an event if the health state is `FAIL`. The default is y.
Event severity when health state is FAIL?	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 5.
Event for health state of CRITICAL?	Set to **y** to raise an event if the health state is `CRITICAL`. The default is y.
Event severity when health state is CRITICAL	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 15.
Event for health state of WARNING?	Set to **y** to raise an event if the health state is `WARNING`. The default is y.
Event severity when health state is WARNING	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Event for health state of OK?	Set to **y** to raise an event if the health state is `OK`. The default is n.
Event severity when health state is OK	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 35.

78.29 JTATransRolledBack

Use this Knowledge Script to obtain a breakdown of the reasons why transactions were rolled back.

78.29.1 Versions of WebLogic Supported

9.0, 9.1, and 9.2

78.29.2 Resource Object

WebLogic Server

78.29.3 Default Schedule

The default interval for this script is Every 15 minutes.

78.29.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default is n.
Timeouts threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of rollbacks due to timeouts since the last sample exceeds this threshold, an event is raised. The default is 0.
Event severity when timeouts exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Resource errors threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of rollbacks due to resource errors since the last sample exceeds this threshold, an event is raised. The default is 0.
Event severity when resource errors exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Application errors threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of rollbacks due to application errors since the last sample exceeds this threshold, an event is raised. The default is 0.
Event severity when application errors exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
System errors threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of rollbacks due to system errors since the last sample exceeds this threshold, an event is raised. The default is 0.

Description	How to Set It
Event severity when system errors exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.

78.30 LogAccessLog

Use this Knowledge Script to monitor entries that are added to the Web server log of a WebLogic Server. The entries that are monitored can be restricted by supplying Perl regular expressions to indicate which entries should be included or excluded from consideration. The script checks only the new log entries that were created since the last time the script examined the log. By monitoring `access.log`, you can gather statistics on HTTP requests and sessions.

78.30.1 Versions of WebLogic Supported

9.0, 9.1, and 9.2

78.30.2 Resource Object

WebLogic Server

78.30.3 Default Schedule

The default interval for this script is Every 15 minutes.

78.30.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default is n.
Number matched threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of log entries that matched the search criteria exceeds this threshold, an event is raised. The default is 0.
Event severity when number matched exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Include filter	Set to a string that is a regular expression that specifies the include filter. The default is *.
Include modifier	Set to a string that is a modifier for the regular expression include filter. The default is a null string.
Exclude filter	Set to a string that is a regular expression that specifies the exclude filter. The default value is a null string.
Exclude modifier	Set to a string that is a modifier for the regular expression exclude filter. The default is a null string.

78.31 LogAccessLogSetPath

Use this Knowledge Script to set the absolute pathname for a Web server log file. The LogAccessLog Knowledge Script needs an absolute pathname for the log file, but the Administration Console of WebLogic Server will accept relative pathnames. This script provides a way to set the absolute path without having to do it through the Administration Console.

78.31.1 Versions of WebLogic Supported

9.0, 9.1, and 9.2

78.31.2 Resource Object

WebLogic Server

78.31.3 Default Schedule

The default interval for this script is Run once.

78.31.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default is y.
Absolute path	The absolute pathname of the log file for the Web server.

78.32 LogWebLogic

Use this Knowledge Script to monitor entries that are added to the log for a WebLogic Server. The entries that are monitored can be restricted by supplying Perl regular expressions that indicate which entries should be included or excluded from consideration. The script checks only the new log entries that were created since the last time the script examined the log.

NOTE: If you are running WebLogic Server 9.x, you must specify an absolute path to the WebLogic log file in order to run the LogWebLogic Knowledge Script successfully. If the LogWebLogic script is run and you have not set an absolute path, you receive the following event message: 'Absolute pathname for log file required'. Use the LogWebLogicSetPath Knowledge Script to specify the absolute path to the WebLogic log file. You will continue to receive an event message until you reboot the WebLogic Server 9.x where the log file resides.

78.32.1 Versions of WebLogic Supported

9.0, 9.1, and 9.2

78.32.2 Resource Object

WebLogic Server

78.32.3 Default Schedule

The default interval for this script is Every 15 minutes.

78.32.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default is n.
Number matched threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of log entries that matched the search criteria exceeds this threshold, an event is raised. The default is 0.
Event severity when number matched exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Include filter	Set to a string that is a regular expression that specifies the include filter. The default is *.
Include modifier	Set to a string that is a modifier for the regular expression include filter. The default is a null string.
Exclude filter	Set to a string that is a regular expression that specifies the exclude filter. The default value is a null string.
Exclude modifier	Set to a string that is a modifier for the regular expression exclude filter. The default is a null string.

78.33 LogWebLogicSetPath

Use this Knowledge Script to set the absolute pathname for a WebLogic Server log file. The LogWebLogic Knowledge Script needs an absolute pathname for the log file, but the Administration Console of WebLogic Server will accept relative pathnames. This script provides a way to set the absolute path without having to do it through the Administration Console.

NOTE: If you are running BEA WebLogic Server 9.x, you must specify an absolute path to the WebLogic log file in order to run the LogWebLogic Knowledge Script successfully. If you try to run the LogWebLogic Knowledge Script without first setting an absolute path, you receive the following event message: 'Absolute pathname for log file required'.

Use the LogWebLogicSetPath Knowledge Script to specify the absolute path to the WebLogic log file. You will continue to receive an event message until you reboot the WebLogic Server 9.x where the log file resides.

78.33.1 Versions of WebLogic Supported

9.0, 9.1, and 9.2

78.33.2 Resource Object

WebLogic Server

78.33.3 Default Schedule

The default interval for this script is Run once.

78.33.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default is y.
Absolute path	The absolute pathname of the WebLogic Server's log file.

78.34 Memory

Use this Knowledge Script to monitor the physical and virtual memory use of a WebLogic Server.

78.34.1 Versions of WebLogic Supported

9.0, 9.1, and 9.2

78.34.2 Resource Object

WebLogic Server

78.34.3 Default Schedule

The default interval for this script is Every 15 minutes.

78.34.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default is n.
Real memory size threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the real memory size of a WebLogic Server in kilobytes exceeds this threshold, an event is raised. The default is –1.
Event severity when real memory size exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Virtual memory size threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the virtual memory size of a WebLogic Server in kilobytes exceeds this threshold, an event is raised. The default is –1.
Event severity when virtual memory size exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Percent of real memory in use threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the percent of real memory in use of a WebLogic Server in kilobytes exceeds this threshold, an event is raised. The default is –1.
Event severity when percent of real memory in use exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.

78.35 MsgDrivenEJBError

Use this Knowledge Script to monitor errors generated by a message-driven EJB. This script reports error statistics for a message-driven EJB.

This script may be used to determine the number of times the message-driven EJB was destroyed due to an exception, and the number of failed attempts to retrieve an EJB from the pool. These values will help monitor the message-driven EJB if errors occur.

78.35.1 Versions of WebLogic Supported

9.0, 9.1, and 9.2

78.35.2 Resource Object

WebLogic Server

78.35.3 Default Schedule

The default interval for this script is Every 15 minutes.

78.35.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default is n.
Destroyed bean instances threshold	Specify a threshold value using an integer value greater than or equal to –1. Use –1 to ignore this threshold. If the number of times since the last sample that a bean instance was destroyed due to a thrown exception exceeds this threshold, an event is raised. The default is 0.
Event severity when destroyed bean instances exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Miss count threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of failed attempts to retrieve a bean from the free pool since the last sample exceeds this threshold, an event is raised. The default is 0.
Event severity when miss count exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.

78.36 MsgDrivenEJBPool

Use this Knowledge Script to monitor for the number or percentage of beans that are in use and idle in a message-driven EJB pool. These values will help determine if the size of the pool has been set properly.

78.36.1 Versions of WebLogic Supported

9.0, 9.1, and 9.2

78.36.2 Resource Object

WebLogic Server

78.36.3 Default Schedule

The default interval for this script is Every 15 minutes.

78.36.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default is n.
Beans idle threshold	Specify a threshold value using an integer greater than or equal to -1. Use -1 to ignore this threshold. If the number of beans that are allocated but idle exceeds this threshold, an event is raised. The default is -1.
Event severity when beans idle exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Beans in use threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of beans in use exceeds this threshold, an event is raised. The default is –1.
Event severity when beans in use exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Percent of pool in use threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the percent of beans available in the pool in use exceeds this threshold, an event is raised. The default is –1.
Event severity when percent of pool in use exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.

78.37 MsgDrivenEJBTrans

Use this Knowledge Script to monitor a message-driven EJB. This script monitors the transaction rates for a message-driven EJB. Transactions are rolled back when timeouts or application, system or resource errors occur. The JTATransRolledBack Knowledge Script provides a breakdown of the reasons for rollbacks.

78.37.1 Versions of WebLogic Supported

9.0, 9.1, and 9.2

78.37.2 Resource Object

WebLogic Server

78.37.3 Default Schedule

The default interval for this script is Every 15 minutes.

78.37.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default is n.
Transactions committed threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of transactions committed since the last sample exceeds this threshold, an event is raised. The default is –1.
Event severity when transactions committed exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Transactions rolled back threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of transactions rolled back since the last sample exceeds this threshold, an event is raised. The default is 0.
Event severity when transactions rolled back exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Transactions timed out threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of transactions timed out since the last sample exceeds this threshold, an event is raised. The default is 0.
Event severity when transactions timed out exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.

78.38 MsgDrivenEJBWait

Use this Knowledge Script to monitor a message-driven EJB. This script monitors the number of times a request had to wait for an EJB and the number of times a request timed out waiting for an EJB. Increasing the cache size may help reduce the number of timeouts.

78.38.1 Versions of WebLogic Supported

9.0, 9.1, and 9.2

78.38.2 Resource Object

WebLogic Server

78.38.3 Default Schedule

The default interval for this script is Every 15 minutes.

78.38.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default is n.
Times waited threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of times since the last sample that clients have waited for a bean exceeds this threshold, an event is raised. The default is –1.
Event severity when times waited exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Timeouts threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of timeouts since the last sample exceeds this threshold, an event is raised. The default is 0.
Event severity when timeouts exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.

78.39 NetIQAgent

Use this Knowledge Script to stop and start the NetIQ agent, which most of the scripts use to gather information from WebLogic servers.

78.39.1 Versions of WebLogic Supported

9.0, 9.1, and 9.2

78.39.2 Resource Object

WebLogic Server

78.39.3 Default Schedule

The default interval for this script is Run once.

78.39.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default is y.
Event severity when NetIQ WebLogic agent cannot be started	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 10.
Event severity when NetIQ WebLogic agent cannot be stopped	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 15.
Event severity when NetIQ WebLogic agent is started	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Event severity when NetIQ WebLogic agent is stopped	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Enable?	Set to **y** to start the NetIQ agent; set to n to stop it. The default is y.

78.40 Report_HealthSummary

Use this Report Knowledge Script to generate a report summarizing the health of monitored WebLogic servers. The report provides data gathered by the HealthCheck Knowledge Script.

78.40.1 Resource Object

AppManager repository

78.40.2 Default Schedule

The default schedule is **Run once**.

78.40.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Data source	Use the following parameters to select the data for your report.
Select computer(s)	Click the **Browse [...]** button to start the data wizard. Use the data wizard to select the computers for your report.
Select time range	Click the **Browse (...)** button to open the time browser. Set a specific or sliding time range for data included in your report.
Select peak weekday(s)	Click the **Browse (...)** button to select the days of the week to include in your report.
Aggregation by	Select the time period (Hour, Minute, or Day) by which the data in your report is aggregated.
Aggregation interval	Select the interval between aggregations of the data in your report. This parameter uses the time period specified in the **Aggregation by** parameter to calculate the interval.
Report Component Selection	Use the following parameters to define which data and statistics are displayed in the report.
Include parameter card?	Set to **y** to include a table in the report that lists parameter settings for the report script. The default is y.
Include Running detail table?	Set to **y** to include data from the Availability detail table in the report. The default is y.
Include Running chart?	Set to **y** to include data from the Availability chart in the report. The default is y.
Threshold on running chart	Specify an integer to set a threshold for the Availability chart. Use -1 to ignore this threshold.
Include WebLogic Ping Response Time detail table?	Set to **y** to include data from the WebLogic Ping Response Time detail table in the report. The default is y.

Description	How to Set It
Include WebLogic Ping Response Time chart?	Set to **y** to include data from the WebLogic Ping Response Time chart in the report. The default is y.
Units for WebLogic Ping Response Time report	Select the measurement units to be used in the WebLogic Ping Response Time report. The default is msec (milliseconds).
Threshold on WebLogic Ping Response Time chart	Specify an integer to set a threshold for the WebLogic Ping Response Time chart. Use -1 to ignore this threshold. The default is 0.
Include WebLogic Connect Time detail table?	Set to **y** to include data from the WebLogic Connect Time detail table in the report. The default is y.
Include WebLogic Connect Time chart?	Set to **y** to include data from the WebLogic Connect Time chart in the report. The default is y.
Units for WebLogic Connect Time report	Select the measurement units to be used in the WebLogic Connect Time report. The default is msec (milliseconds).
Threshold on WebLogic Connect Time chart	Specify an integer to set a threshold for the WebLogic Connect Time chart. Use -1 to ignore this threshold. The default is 0.
Report settings	Use the following parameters to define the graphical presentation of data, the folder where the report is generated, and properties that identify the report.
Customize chart appearance	Click the **Browse (...)** button to open the Chart Settings window. Define the graphic properties of the charts in your report. The default is Ribbon.
Select report location	Click the **Browse (...)** button to open the Publishing Options window. Define the report filename and specify a default folder this report. The default is WebLogicSvr_HealthSummary
Add job ID to output folder name?	Set to **y** to append the job ID to the name of the output folder. This is helpful to make the correlation between a specific instance of a Report Script and the corresponding report. The default is n.
Index-Report Title	Click in the Value column, and click the **Browse (...)** button to open the Report Properties window. Set the properties parameters as desired The default title is WebLogicSvr_HealthSummary.
Add time stamp to title?	Set to y to append a time stamp to the title of the report, making each title unique. The time stamp is made up of the date and time the report was generated. Adding a time stamp is useful in order to run consecutive iterations of the same report without overwriting previous output. The default is n.
Event notification	Use the following parameters to raise events associated with generating the report, and to set severity levels for those events.

Description	How to Set It
Generate event on success?	Set to **y** to raise an event when the report is successfully generated. The default is y.
Severity level for report success	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 35 (magenta level indicator).
Severity level for report with no data	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25 (blue level indicator).
Severity level for report failure.	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 5 (red level indicator).

78.41 Report_PerfSummary

Use this Report Knowledge Script to generate a report summarizing the throughput performance of monitored WebLogic servers. The report provides data from the ServerCPU and ServerRequests Knowledge Scripts.

78.41.1 Resource Object

AppManager repository

78.41.2 Default Schedule

The default schedule is **Run once**.

78.41.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Data source	Use the following parameters to select the data for your report.
Select computer(s)	Click the **Browse [...]** button to start the data wizard. Use the data wizard to select the computers for your report.
Select time range	Click the **Browse (...)** button to open the time browser. Set a specific or sliding time range for data included in your report.
Select peak weekday(s)	Click the **Browse (...)** button to select the days of the week to include in your report.
Aggregation by	Select the time period (Hour, Minute, or Day) by which the data in your report is aggregated.
Aggregation interval	Select the interval between aggregations of the data in your report. This parameter uses the time period specified in the **Aggregation by** parameter to calculate the interval.
Report Component Selection	Use the following parameters to define which data and statistics are displayed in the report.
Include parameter card?	Set to **y** to include a table in the report that lists parameter settings for the report script. The default is y.
Include CPU Utilization detail table?	Set to **y** to include data from the CPU Utilization detail table in the report. The default is y.
Include CPU Utilization chart?	Set to **y** to include data from the CPU Utilization chart in the report. The default is y.
Threshold on CPU Utilization chart?	Specify an integer to set a threshold for the CPU Utilization chart. Use -1 to ignore this threshold. The default is 0.
Include Throughput detail table?	Set to **y** to include data from the Throughput detail table in the report. The default is y.

Description	How to Set It
Include Throughput chart?	Set to **y** to include data from the Throughput chart in the report. The default is y.
Threshold on Throughput chart	Specify an integer to set a threshold for the Throughput chart. Use -1 to ignore this threshold. The default is 0.
Report settings	Use the following parameters to define the graphical presentation of data, the folder where the report is generated, and properties that identify the report.
Customize chart appearance	Click the **Browse (...)** button to open the Chart Settings window. Define the graphic properties of the charts in your report. The default is Ribbon.
Select report location	Click the **Browse (...)** button to open the Publishing Options window. Define the report filename and specify a default folder this report. The default is WebLogicSvr_PerfSummary.
Add job ID to output folder name?	Set to **y** to append the job ID to the name of the output folder. This is helpful to make the correlation between a specific instance of a Report Script and the corresponding report. The default is n.
Index-Report Title	Click in the Value column, and click the **Browse (...)** button to open the Report Properties window. Set the properties parameters as desired. The default title is WebLogicSvr_Perf Summary.
Add time stamp to title?	Set to **y** to append a time stamp to the title of the report, making each title unique. The time stamp is made up of the date and time the report was generated. Adding a time stamp is useful in order to run consecutive iterations of the same report without overwriting previous output. The default is n.
Event notification	Use the following parameters to raise events associated with generating the report, and to set severity levels for those events.
Generate event on success?	Set to **y** to raise an event when the report is successfully generated. The default is y.
Severity level for report success	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 35 (magenta level indicator).
Severity level for report with no data	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25 (blue level indicator).
Severity level for report failure.	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 5 (red level indicator).

78.42 SecurityUserLockout

Use this Knowledge Script to monitor statistics on the number of users locked out because invalid usernames and/or passwords were supplied at login.

78.42.1 Versions of WebLogic Supported

9.0, 9.1, and 9.2

78.42.2 Resource Object

WebLogic Server

78.42.3 Default Schedule

The default interval for this script is Every 15 minutes.

78.42.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default is n.
User lockouts threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of user lockouts since the last sample exceeds this threshold, an event is raised. The default is 0.
Event severity when user lockouts exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Invalid logins threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of invalid logins since the last sample exceeds this threshold, an event is raised. The default is 0.
Event severity when invalid logins exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Invalid logins while user locked out threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of invalid logins while a user was locked out since the last sample exceeds this threshold, an event is raised. The default is 0.
Event severity when invalid logins while user locked out exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.

Description	How to Set It
User unlocks threshold	Specify a threshold value using an integer greater than or equal to −1. Use −1 to ignore this threshold. If the number of times since the last sample that a user was unlocked exceeds this threshold, an event is raised. The default is −1.
Event severity when user unlocks exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Locked users threshold	Specify a threshold value using an integer greater than or equal to −1. Use −1 to ignore this threshold. If the current number of locked users exceeds this threshold, an event is raised. The default is 0.
Event severity when locked users exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.

78.43 ServerCPU

Use this Knowledge Script to monitor the utilization of a WebLogic Server. This script monitors the amount of CPU the server is consuming.

This script may be used to track how busy a server is at a given time.

78.43.1 Versions of WebLogic Supported

9.0, 9.1, and 9.2

78.43.2 Resource Object

WebLogic Server

78.43.3 Default Schedule

The default interval for this script is Every 15 minutes.

78.43.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default is n.
CPU usage threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the CPU utilization for the WebLogic Server exceeds this threshold, an event is raised. The default is –1.
Event severity when CPU usage exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.

78.44 ServerHealthState

Use this Knowledge Script to monitor the health state of a WebLogic Server.

78.44.1 Versions of WebLogic Supported

9.0, 9.1, and 9.2

78.44.2 Resource Object

WebLogic Server

78.44.3 Default Schedule

The default interval for this script is Every 15 minutes.

78.44.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Collect data?	Set to **y** to collect data for reports and graphs. The default is n.
Scale to 100?	Set to **y** to scale the values to 100. The default values range from 0-3, where 0 is `OK`, and 3 is `FAIL`. Setting to y will scale the values from 0-100, where 0 is `FAIL` and 100 is `OK`. The default is n.
Event for health state of FAIL?	Set to **y** to raise an event if the health state is `FAIL`. The default is y.
Event severity when health state is FAIL?	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 5.
Event for health state of CRITICAL?	Set to **y** to raise an event if the health state is `CRITICAL`. The default is y.
Event severity when health state is CRITICAL	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 15.
Event for health state of WARNING?	Set to **y** to raise an event if the health state is `WARNING`. The default is y.
Event severity when health state is WARNING	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Event for health state of OK?	Set to **y** to raise an event if the health state is `OK`. The default is n.
Event severity when health state is OK	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 35.

78.45 ServerJVMHeap

Use this Knowledge Script to monitor the utilization of a WebLogic Server. This script monitors the percentage of a WebLogic server's JVM heap that is currently used. If this value is consistently near 100%, consider increasing the size of the WebLogic server's JVM heap.

78.45.1 Versions of WebLogic Supported

9.0, 9.1, and 9.2

78.45.2 Resource Object

WebLogic Server

78.45.3 Default Schedule

The default interval for this script is Every 15 minutes.

78.45.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default is n.
Heap size threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the current size of the heap in KB exceeds this threshold, an event is raised. The default is –1.
Event severity when heap size exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Free heap threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of KB available in the heap falls below this threshold, an event is raised. The default is –1.
Event severity when free heap falls below threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Percent heap used threshold	Specify a threshold value using a real number greater than or equal to –1. Use –1 to ignore this threshold. If the percentage of the JVM Heap that is currently used exceeds this threshold, an event is raised. The default is –1.
Event severity when percent heap used exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.

78.46 ServerRequests

Use this Knowledge Script to monitor the utilization and throughput of a WebLogic Server. This script monitors the server's Execute Queue.

This script may be used to track how busy a server is at a given time.

NOTE: If the number of requests waiting on the Execute Queue is 0, the value for the "Oldest request" on the queue is not returned and the threshold comparison is not performed.

78.46.1 Versions of WebLogic Supported

9.0, 9.1, and 9.2

78.46.2 Resource Object

WebLogic Server

78.46.3 Default Schedule

The default interval for this script is Every 15 minutes.

78.46.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default is n.
Throughput threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of requests the WebLogic Server has serviced since the last sample exceeds this threshold, an event is raised. The default is –1.
Event severity when throughput exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Waiting requests threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of requests waiting on the Execute Queue exceeds this threshold, an event is raised. The default is –1.
Event severity when waiting requests exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Oldest request threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of seconds the oldest request has been on the Execute Queue exceeds this threshold, an event is raised. The default is –1.

Description	How to Set It
Event severity when oldest request exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Idle threads threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of idle threads in the Execute Queue exceeds this threshold, an event is raised. The default is –1.
Event severity when idle threads exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Percent threads in use threshold	Specify a threshold value using an integer greater than or equal to –1 and less than or equal to 100. Use –1 to ignore this threshold. If the percent of threads in the Execute Queue exceeds this threshold, an event is raised. The default is –1.
Event severity when percent threads in use exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.

78.47 ServerSecurity

Use this Knowledge Script to monitor statistics on the number of users locked out because invalid usernames and/or passwords were supplied at login.

78.47.1 Versions of WebLogic Supported

9.0, 9.1, and 9.2

78.47.2 Resource Object

WebLogic Server

78.47.3 Default Schedule

The default interval for this script is Every 15 minutes.

78.47.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default is n.
User lockouts threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of user lockouts since the last sample exceeds this threshold, an event is raised. The default is 0.
Event severity when user lockouts exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Invalid logins threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of invalid logins since the last sample exceeds this threshold, an event is raised. The default is 0.
Event severity when invalid logins exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Invalid logins while user locked out threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of invalid logins while a user was locked out since the last sample exceeds this threshold, an event is raised. The default is 0.
Event severity when invalid logins while user locked out exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.

Description	How to Set It
User unlocks threshold	Specify a threshold value using an integer greater than or equal to −1. Use −1 to ignore this threshold. If the number of times since the last sample that a user was unlocked exceeds this threshold, an event is raised. The default is −1.
Event severity when user unlocks exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Locked users threshold	Specify a threshold value using an integer greater than or equal to −1. Use −1 to ignore this threshold. If the current number of locked users exceeds this threshold, an event is raised. The default is 0.
Event severity when locked users exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.

78.48 ServerSockets

Use this Knowledge Script to monitor the number of sockets a WebLogic Server has open.

This script may be used to track the number of server connections and how busy a WebLogic Server is.

78.48.1 Versions of WebLogic Supported

9.0, 9.1, and 9.2

78.48.2 Resource Object

WebLogic Server

78.48.3 Default Schedule

The default interval for this script is Every 15 minutes.

78.48.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default is n.
Sockets currently open threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of sockets currently open exceeds this threshold, an event is raised. The default is –1.
Event severity when sockets currently open exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Total sockets opened threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of sockets opened since the last sample exceeds this threshold, an event is raised. The default is –1.
Event severity when total sockets opened exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.

78.49 ServerState

Use this Knowledge Script to monitor the state of a WebLogic Server as reported by the WebLogic Server. If the state is anything other than RUNNING, the server may not be responding properly.

78.49.1 Versions of WebLogic Supported

9.0, 9.1, and 9.2

78.49.2 Resource Object

WebLogic Server

78.49.3 Default Schedule

The default interval for this script is Every 15 minutes.

78.49.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Collect data?	Set to **y** to collect data for reports and graphs. The default is n.
Event for any state other than RUNNING?	Set to **y** to raise an event if the health state is not RUNNING. The default is y.
Event severity when health state is not RUNNING?	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 5.
Event for state of RUNNING?	Set to **y** to raise an event if the state is RUNNING. The default is n.
Event severity when state is RUNNING	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 35.

78.50 ServerUptime

Use this Knowledge Script to monitor how many hours a WebLogic Server has been running.

78.50.1 Versions of WebLogic Supported

9.0, 9.1, and 9.2

78.50.2 Resource Object

WebLogic Server

78.50.3 Default Schedule

The default interval for this script is Every 15 minutes.

78.50.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default is n.
Event severity when server has restarted	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.

78.51 ServletExecTime

Use this Knowledge Script to monitor the execution times and number of times that the servlets of a Web application were invoked. The short-term average is the average execution time since the last sample; the long-term average is the average execution time since the WebLogic server was started.

The overall average execution time of a servlet is calculated as the total time that the servlet has run since the WebLogic server was started, divided by the total number of times the servlet was invoked since the WebLogic server was started. This average will not tend to change very much if the WebLogic server has been running for a long time.

The short-term average execution time of a servlet is calculated as the time that the servlet has run since the last sample, divided by the number of times the servlets was invoked since the last sample. This average gives a better impression of how well the servlet has been performing since the last sample.

78.51.1 Versions of WebLogic Supported

9.0, 9.1, and 9.2

78.51.2 Resource Object

WebLogic Server

78.51.3 Default Schedule

The default interval for this script is Every 15 minutes.

78.51.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default is n.
Overall average threshold in secs	Specify a threshold value using a real number greater than or equal to –1. Use –1 to ignore this threshold. If the overall average execution time (in seconds) of the servlet exceeds this threshold, an event is raised. The default is –1.
Event severity when overall average exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Short term average threshold in secs	Specify a threshold value using a real number greater than or equal to –1. Use –1 to ignore this threshold. If the short-term average execution time (in seconds) of the servlet exceeds this threshold, an event is raised. The default is –1.
Event severity when short-term average exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.

Description	How to Set It
Longest time threshold in secs	Specify a threshold value using a real number greater than or equal to –1. Use –1 to ignore this threshold. If the longest execution time (in seconds) of the servlet exceeds this threshold, an event is raised. The default is –1.
Event severity when longest time exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Shortest time threshold	Specify a threshold value using a real number greater than or equal to –1. Use –1 to ignore this threshold. If the shortest execution time (in seconds) of the servlet exceeds this threshold, an event is raised. The default is –1.
Event severity when shortest time exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Invocations threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of invocations of the servlet since the last sample exceeds this threshold, an event is raised. The default is –1.
Event severity when invocations exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Reloads threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of reloads of the servlet since the last sample exceeds this threshold, an event is raised. The default is –1.
Event severity when reloads exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.

78.52 StartAdminServer

Use this Knowledge Script to start a WebLogic Server as the Administration Server for a domain.

78.52.1 Versions of WebLogic Supported

9.0, 9.1, and 9.2

78.52.2 Resource Object

WebLogic Server

78.52.3 Default Schedule

The default interval for this script is Run once.

78.52.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default is y.
Event severity when script fails	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 10.
Event severity when server cannot be started	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 10.
Event severity when server is started	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Start Command Script	Enter the name (with the full path) of the script that you use to start an Administration Server. The default is blank (no default). This is a mandatory field.
Start Command Parameters	Specify conditions to apply to the Start Command parameter.
Start Script Parameters	Enter the parameters for the start script, if any.
Restart server if already running? (y/n)	Set to **y** to restart the server if it is already running. The default is y.
Pass name of server, IP address, port, admin username and password to Start Script?	Set to **y** to pass these parameters to the Start Script. These parameters will be added to the end of the string supplied for Start Script. The default is n.
Start time limit	Set to the number of seconds within which the WebLogic Server should complete initialization. The default is 300.

78.53 StartServer

Use this Knowledge Script to start a managed WebLogic Server.

78.53.1 Versions of WebLogic Supported

9.0, 9.1, and 9.2

78.53.2 Resource Object

WebLogic Server

78.53.3 Default Schedule

The default interval for this script is Run once.

78.53.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default is y.
Event severity when server cannot be started	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 10.
Event severity when server is started	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Start Script	Set to the name of the script that you use to start an Administration Server. The default is blank (no default).
Start Command Parameters	Specify conditions to apply to the Start Command parameter.
Restart server if already running?	Set to **y** to restart the server if it is already running. The default is y.
Pass name of server, IP address, port, admin username and password to Start Script?	Set to **y** to pass these parameters to the Start Script. These parameters will be added to the end of the string supplied for Start Script. The default is n.
Start time limit	Set to the number of seconds within which the WebLogic Server should complete initialization. The default is 300.

78.54 StartServerNodeMgr

Use this Knowledge Script to start WebLogic Server as a Managed Server using the Node Manager.

78.54.1 Versions of WebLogic Supported

9.0, 9.1, and 9.2

78.54.2 Resource Object

WebLogic Server

78.54.3 Default Schedule

The default interval for this script is Run once.

78.54.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default is y.
Event severity when server cannot be started	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 10.
Event severity when server is started	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Restart server if already running?	Set to **y** to restart the server if it is already running. The default is y.

78.55 StatefulEJBCache

Use this Knowledge Script to monitor statistics for a Stateful EJB. This script reports caching statistics for a Stateful EJB.

This script may be used to determine a cache hit ratio and how frequently instances of the Stateful EJB are rendered active or passive. These values will help determine if the size of the cache is appropriate.

78.55.1 Versions of WebLogic Supported

9.0, 9.1, and 9.2

78.55.2 Resource Object

WebLogic Server

78.55.3 Default Schedule

The default interval for this script is Every 15 minutes.

78.55.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default is n.
Current beans threshold	Specify a threshold value using an integer value greater than or equal to –1. Use –1 to ignore this threshold. If the number of beans currently in use exceeds this threshold, an event is raised. The default is –1.
Event severity when current beans exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Cache accesses threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of cache accesses since the last sample exceeds this threshold, an event is raised. The default is –1.
Event severity when cache accesses exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Cache hit ratio threshold	Specify a threshold value using a real number greater than or equal to –1. Use –1 to ignore this threshold. If the cache hit ratio (expressed as a percentage) since the last sample falls below this threshold, an event is raised. The default is –1.
Event severity when cache hit ratio falls below threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.

Description	How to Set It
Activations threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of activations since the last sample exceeds this threshold, an event is raised. The default is –1.
Event severity when activations exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Passivations threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of passivations since the last sample exceeds this threshold, an event is raised. The default is –1.
Event severity when passivations exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Cache miss count threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the cache miss count since the last sample exceeds this threshold, an event is raised. The default is –1.
Event severity when cache miss count exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.

78.56 StatefulEJBTrans

Use this Knowledge Script to monitor Stateful EJBs. This script monitors the transaction rates for a Stateful EJB. Transactions are rolled back when timeouts or application, system, or resource errors occur. The JTATransRolledBack Knowledge Script provides a breakdown of the reasons for rollbacks.

78.56.1 Versions of WebLogic Supported

9.0, 9.1, and 9.2

78.56.2 Resource Object

WebLogic Server

78.56.3 Default Schedule

The default interval for this script is Every 15 minutes.

78.56.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default is n.
Transactions committed threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of transactions committed since the last sample exceeds this threshold, an event is raised. The default is –1.
Event severity when transactions committed exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Transactions rolled back threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of transactions rolled back since the last sample exceeds this threshold, an event is raised. The default is 0.
Event severity when transactions rolled back exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Transactions timed out threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of transactions timed out since the last sample exceeds this threshold, an event is raised. The default is 0.
Event severity when transactions timed out exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.

78.57 StatefulEJBWait

Use this Knowledge Script to monitor Stateful EJBs. This script monitors the number of times a request had to wait for an EJB and the number of times a request timed out waiting for an EJB. Increasing the cache size may help reduce the number of timeouts.

78.57.1 Versions of WebLogic Supported

9.0, 9.1, and 9.2

78.57.2 Resource Object

WebLogic Server

78.57.3 Default Schedule

The default interval for this script is Every 15 minutes.

78.57.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default is n.
Times waited threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of times since the last sample that clients have waited for a bean exceeds this threshold, an event is raised. The default is –1.
Event severity when times waited exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Timeouts threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of timeouts since the last sample exceeds this threshold, an event is raised. The default is 0.
Event severity when timeouts exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.

78.58 StatelessEJBError

Use this Knowledge Script to monitor errors generated by a Stateless EJB. This script reports error statistics for a Stateless EJB.

This script may be used to determine the number of times the Stateless EJB was destroyed due to an exception, and the number of failed attempts to retrieve an EJB from the pool. These values will help monitor the Stateless EJB if errors occur.

78.58.1 Versions of WebLogic Supported

9.0, 9.1, and 9.2

78.58.2 Resource Object

WebLogic Server

78.58.3 Default Schedule

The default interval for this script is Every 15 minutes.

78.58.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default is n.
Destroyed bean instances threshold	Specify a threshold value using an integer value greater than or equal to –1. Use –1 to ignore this threshold. If the number of times since the last sample that a bean instance was destroyed due to a thrown exception exceeds this threshold, an event is raised. The default is 0.
Event severity when destroyed bean instances exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Miss count threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of failed attempts to retrieve a bean from the free pool since the last sample exceeds this threshold, an event is raised. The default is 0.
Event severity when miss count exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.

78.59 StatelessEJBPool

Use this Knowledge Script to monitor for the number or percentage of in-use and idle beans in a Stateless EJB pool. These values will help determine if the size of the pool has been set properly.

78.59.1 Versions of WebLogic Supported

9.0, 9.1, and 9.2

78.59.2 Resource Object

WebLogic Server

78.59.3 Default Schedule

The default interval for this script is Every 15 minutes.

78.59.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default is n.
Beans idle threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of beans that are allocated but idle exceeds this threshold, an event is raised. The default is –1.
Event severity when beans idle exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Beans in use threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of beans in use exceeds this threshold, an event is raised. The default is –1.
Event severity when beans in use exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Percent of pool in use threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the percentage of beans in the pool that are in use exceeds this threshold, an event is raised. The default is –1.
Event severity when percent of pool in use exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.

78.60 StatelessEJBTrans

Use this Knowledge Script to monitor Stateless EJBs. This script monitors the transaction rates for a Stateless EJB. Transactions are rolled back when timeouts or application, system or resource errors occur. The JTATransRolledBack Knowledge Script provides a breakdown of the reasons for rollbacks.

78.60.1 Versions of WebLogic Supported

9.0, 9.1, and 9.2

78.60.2 Resource Object

WebLogic Server

78.60.3 Default Schedule

The default interval for this script is Every 15 minutes.

78.60.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default is n.
Transactions committed threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of transactions committed since the last sample exceeds this threshold, an event is raised. The default is –1.
Event severity when transactions committed exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Transactions rolled back threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of transactions rolled back since the last sample exceeds this threshold, an event is raised. The default is 0.
Event severity when transactions rolled back exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Transactions timed out threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of transactions timed out since the last sample exceeds this threshold, an event is raised. The default is 0.
Event severity when transactions timed out exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.

78.61 StatelessEJBWait

Use this Knowledge Script to monitor Stateless EJBs. This script monitors the number of times a request had to wait for an EJB and the number of times a request timed out waiting for an EJB. Increasing the cache size may help reduce the number of timeouts.

78.61.1 Versions of WebLogic Supported

9.0, 9.1, and 9.2

78.61.2 Resource Object

WebLogic Server

78.61.3 Default Schedule

The default interval for this script is Every 15 minutes.

78.61.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default is n.
Times waited threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of times since the last sample that clients have waited for a bean exceeds this threshold, an event is raised. The default is –1.
Event severity when times waited exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Timeouts threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of timeouts since the last sample exceeds this threshold, an event is raised. The default is 0.
Event severity when timeouts exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.

78.62 StopServer

Use this Knowledge Script to shut down a WebLogic Server.

78.62.1 Versions of WebLogic Supported

9.0, 9.1, and 9.2

78.62.2 Resource Object

WebLogic Server

78.62.3 Default Schedule

The default interval for this script is Run once.

78.62.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default is y.
Event severity when unable to stop server	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 10.
Event severity when server is stopped	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.

78.63 TransCateg

Use this Knowledge Script to monitor statistics for transaction categories. This script monitors the transactions that have completed on a WebLogic Server since the last sample on a per transaction category basis. Transactions are rolled back when timeouts or application, system or resource errors occur. The TransCategRollBacks Knowledge Script provides a breakdown of the reasons for rollbacks.

78.63.1 Versions of WebLogic Supported

9.0, 9.1, and 9.2

78.63.2 Resource Object

WebLogic Server

78.63.3 Default Schedule

The default interval for this script is Every 15 minutes.

78.63.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default is n.
Transactions completed threshold	Specify a threshold value using an integer greater than or equal to -1. Use -1 to ignore this threshold. If the number of transactions completed since the last sample exceeds this threshold, an event is raised. The default is -1.
Event severity when transactions completed exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Transactions committed threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of transactions committed since the last sample exceeds this threshold, an event is raised. The default is –1.
Event severity when transactions committed exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Transactions rolled back threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of transactions rolled back since the last sample exceeds this threshold, an event is raised. The default is 0.

Description	How to Set It
Event severity when transactions rolled back exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Average commit time threshold in secs	Specify a threshold value using a real number greater than or equal to –1. Use –1 to ignore this threshold. If the average commit time in seconds exceeds this threshold, an event is raised. The default is –1.
Event severity when average commit time exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Heuristic completes threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of heuristic completes since the last sample exceeds this threshold, an event is raised. The default is –1.
Event severity when heuristic completes exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Transactions abandoned threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of transactions abandoned since the last sample exceeds this threshold, an event is raised. The default is 0.
Event severity when transactions abandoned exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.

78.64 TransCategRollBacks

Use this Knowledge Script to monitor the reasons why transactions were rolled back. This script reports this information on a per transaction category basis.

78.64.1 Versions of WebLogic Supported

9.0, 9.1, and 9.2

78.64.2 Resource Object

WebLogic Server

78.64.3 Default Schedule

The default interval for this script is Every 15 minutes.

78.64.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default is n.
Timeouts threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of rollbacks due to timeouts since the last sample exceeds this threshold, an event is raised. The default is 0.
Event severity when timeouts exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Resource errors threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of rollbacks due to resource errors since the last sample exceeds this threshold, an event is raised. The default is 0.
Event severity when resource errors exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Application errors threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of rollbacks due to application errors since the last sample exceeds this threshold, an event is raised. The default is 0.

Description	How to Set It
Event severity when application errors exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
System errors threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of rollbacks due to system errors since the last sample exceeds this threshold, an event is raised. The default is 0.
Event severity when system errors exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.

78.65 TransResHealthState

Use this Knowledge Script to monitor the health state of the transactional resources of a WebLogic Server.

78.65.1 Versions of WebLogic Supported

9.0, 9.1, and 9.2

78.65.2 Resource Object

WebLogic Server

78.65.3 Default Schedule

The default interval for this script is Every 15 minutes.

78.65.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Collect data?	Set to **y** to collect data for reports and graphs. The default is n.
Scale to 100?	Set to **y** to scale the values to 100. The default values range from 0-3, where 0 is `OK`, and 3 is `FAIL`. Setting to y will scale the values from 0-100, where 0 is `FAIL` and 100 is `OK`. The default is n.
Event for health state of FAIL?	Set to **y** to raise an event if the health state is `FAIL`. The default is y.
Event severity when health state is FAIL?	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 5.
Event for health state of CRITICAL?	Set to **y** to raise an event if the health state is `CRITICAL`. The default is y.
Event severity when health state is CRITICAL	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 15.
Event for health state of WARNING?	Set to **y** to raise an event if the health state is `WARNING`. The default is y.
Event severity when health state is WARNING	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Event for health state of OK?	Set to **y** to raise an event if the health state is `OK`. The default is n.
Event severity when health state is OK	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 35.

78.66 TransResHeuristics

Use this Knowledge Script to monitor the reasons why transactions for transactional resources completed with an heuristic status. This script monitors the transactions that completed with a heuristic status for each of a WebLogic server's transactional resources. Transactions are rolled back when timeouts or application, system or resource errors occur.

78.66.1 Versions of WebLogic Supported

9.0, 9.1, and 9.2

78.66.2 Resource Object

WebLogic Server

78.66.3 Default Schedule

The default interval for this script is Every 15 minutes.

78.66.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default is n.
Commits threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of heuristic commits since the last sample exceeds this threshold, an event is raised. The default is –1.
Event severity when commits exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Rollbacks threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of heuristic rollbacks the last sample exceeds this threshold, an event is raised. The default is 0.
Event severity when rollbacks exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.

Description	How to Set It
Mixed threshold	Specify a threshold value using an integer greater than or equal to −1. Use −1 to ignore this threshold. If the number of mixed heuristics since the last sample exceeds this threshold, an event is raised. The default is −1.
Event severity when mixed heuristics exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Hazards threshold	Specify a threshold value using an integer greater than or equal to −1. Use −1 to ignore this threshold. If the number of heuristic hazards since the last sample exceeds this threshold, an event is raised. The default is 0.
Event severity when hazards exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.

78.67 TransResources

Use this Knowledge Script to monitor statistics for transactional resources. This script monitors the transactions that have completed on a WebLogic server since the last sample on a per transactional resource basis. Transactions are rolled back when timeouts or application, system or resource errors occur.

78.67.1 Versions of WebLogic Supported

9.0, 9.1, and 9.2

78.67.2 Resource Object

WebLogic Server

78.67.3 Default Schedule

The default interval for this script is Every 15 minutes.

78.67.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default is n.
Transactions completed threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of transactions completed since the last sample exceeds this threshold, an event is raised. The default is –1.
Event severity when transactions completed exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Transactions committed threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of transactions committed since the last sample exceeds this threshold, an event is raised. The default is –1.
Event severity when transactions committed exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Transactions rolled back threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of transactions rolled back since the last sample exceeds this threshold, an event is raised. The default is 0.

Description	How to Set It
Event severity when transactions rolled back exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Heuristic completes threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of heuristic completes since the last sample exceeds this threshold, an event is raised. The default is –1.
Event severity when heuristic completes exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.

78.68 WebAppSessions

Use this Knowledge Script to monitor Web applications. This script monitors the current number of sessions of a Web application and the number of sessions that have been run since the last sample.

78.68.1 Versions of WebLogic Supported

9.0, 9.1, and 9.2

78.68.2 Resource Object

WebLogic Server

78.68.3 Default Schedule

The default interval for this script is Every 15 minutes.

78.68.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default is y.
Collect data?	Set to **y** to collect data for reports and graphs. The default is n.
Current sessions threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the current number of sessions of the Web Application exceeds the threshold, an event is raised. The default is –1.
Event severity when current sessions exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Peak sessions threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the peak number of concurrent sessions of the Web Application exceeds the threshold, an event is raised. The default is –1.
Event severity when peak sessions exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Sessions run threshold	Specify a threshold value using an integer greater than or equal to –1. Use –1 to ignore this threshold. If the number of sessions of the Web Application run since the last sample exceeds the threshold, an event is raised. The default is 0.

Description	How to Set It
Event severity when sessions run exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.

79 Web-RT Knowledge Scripts

The Web-RT category provides the following Knowledge Scripts for monitoring Web sites using AppManager ResponseTime for Web.

If you choose to collect data, each Knowledge Script generates the following data streams:

- **Availability.** The availability data point is always one of the following values:
  - 1 or 100 = the test was successful
  - 0 = the test was not successful

  The Availability data point is an indication of whether the response-time test succeeded or failed. If, for example, a connection to the server was established but the test message could not be sent, the Availability data point is 0, which indicates not available or not successful.
- **Response time**. You have two options for collecting response-time data:
  - **Overall response time**. The information returned by this data stream is also saved with the data point, and can be viewed by double-clicking the data point in the Graph Pane or Chart Console.
  - **Response-time Breakdown**. If enabled as separate parameters, you can also collect up to 5 response-time breakdown data streams. These data streams are individual data points for the different parts of the Knowledge Script transaction that are timed.

From the Knowledge Script view of the Control Center Console, you can access more information about any Knowledge Script by selecting it and pressing **F1**. In the Operator Console, click any Knowledge Script in the Knowledge Script pane and press **F1**.

Knowledge Script	What It Does
CheckURL	Monitors availability and performance of a single URL, including validating and searching for text, links, and objects. This Knowledge Script is generated from the URL Check Recorder extension.
FTP	Monitors the availability of an FTP site, and verifies that a specified file can be downloaded from the site.
NNTPConnect	Monitors the availability of an NNTP server.
ReceiveInternetMail	Monitors availability and response time to receive an Internet mail message using the POP3 protocol.
Report_Web-RT_Mail	Generates a report of response time and availability for the Web-RT InternetMail Knowledge Scripts.
Report_Web-RT_Steps	Generates a report of response time and availability for the steps in WebTransaction Knowledge Scripts.

Knowledge Script	What It Does
Report_Web-RT_URLCheck	Generates a report of percent availability for URL Check Recorder Knowledge Scripts.
Report_Web-RT_Web	Generates a report of response time and availability for the WebTransaction Knowledge Scripts.
SendAndReceiveInternetMail	Monitors availability and the response time taken to send and receive an Internet mail message using POP3 and SMTP protocols.
SendInternetMail	Monitors availability and the response time taken to send an Internet mail message using the SMTP protocol.
SMTPConnect	Monitors the availability of an SMTP server.
TakeDesktopOwnership	Reassigns control of the desktop on the managed client to AppManager ResponseTime for Web.
URLCheck	Monitors availability and performance of URLs, including validating and searching for text, links, and objects. This Knowledge Script is generated from the URL Check Recorder extension.
WebTransaction	Monitors availability and response time for Web transactions. This Knowledge Script is generated from the Web Recorder extension.

79.1 AppManager ResponseTime for Web Version Compatibility

Knowledge Scripts from versions of AppManager ResponseTime for Web earlier than version 6.4 are not supported. New Knowledge Scripts that you create with AppManager ResponseTime for Web 7.x are not backward-compatible and cannot run on older modules.

When you upgrade your version of AppManager ResponseTime for Web, also upgrade all of your managed clients so that they are all at the same level. You must re-record or recreate any Knowledge Scripts you created with versions of Web Recorder older than 2.2 after you install the newer version. You must upgrade all other backlevel Knowledge Scripts. You can do this by opening them in the new recorder, saving them, and checking them back in. Backlevel Knowledge Scripts are not supported unless you upgrade them.

The following table provides a more detailed explanation of version compatibility:

Versions of AppManager ResponseTime for Web and Extensions	Description and Compatibility
ResponseTime for Web 1.2 (shipped with AppManager v5.0.1)	Knowledge Scripts from AppManager for WebServices (WebServices Knowledge Script category) were still supported.
ResponseTime for Web 2.0 (Web-download package)	URL Check Recorder extension replaces WebServices Knowledge Scripts. WebServices and WebTransaction Knowledge Scripts were still supported.
ResponseTime for Web 2.1 (Web-download package)	URL Check Recorder added support for WinHTTP. WebServices and WebTransaction Knowledge Scripts still supported.
ResponseTime for Web 2.2 (Web-download package; shipped with AppManager 6.0)	Major upgrade of Web Recorder. • WebTransaction Knowledge Scripts not backward-compatible. • WebServices and older WebTransaction Knowledge Scripts no longer supported.
ResponseTime for Web 6.2 (Web-download package, and shipped as an additional installation for AppManager 6.0.2)	Major upgrade of Web Recorder. • New WebTransaction Knowledge Scripts not backward-compatible. • Older Knowledge Scripts (v2.2 and later) continue to run. Minor upgrade of URL Check Recorder. • New URLCheck Knowledge Scripts not backward-compatible. • Older Knowledge Scripts (v2.2 and later) continue to run.

Versions of AppManager ResponseTime for Web and Extensions	Description and Compatibility
ResponseTime for Web 6.3 (Web-download package)	Minor upgrade of Web Recorder. • New WebTransaction Knowledge Scripts not backward-compatible. • Older Knowledge Scripts (v2.2 and later) continue to run. Major upgrade of URL Check Recorder. • New URLCheck Knowledge Scripts not backward-compatible. • Older Knowledge Scripts (v2.2 and later) continue to run.
ResponseTime for Web 6.4 (Web-download package)	Upgrade of all Knowledge Scripts. • FTP, InternetMail, NNTPConnect, and SMTPConnect Knowledge Scripts not backward-compatible. • Older Knowledge Scripts (v2.2 and later) continue to run. Major upgrade of Web Recorder. • New WebTransaction Knowledge Scripts not backward-compatible. • Older Knowledge Scripts (v6.2 and later) continue to run. • WebTransaction Knowledge Scripts v2.2 and earlier must be re-recorded. Major upgrade of URL Check Recorder. • New URLCheck Knowledge Scripts not backward-compatible. • Older Knowledge Scripts (v2.2 and later) continue to run.

Versions of AppManager ResponseTime for Web and Extensions	Description and Compatibility
ResponseTime for Web 7.0 (Shipped with AppManager version 7.0)	Upgrade of all Knowledge Scripts. • FTP, InternetMail, NNTPConnect, and SMTPConnect Knowledge Scripts not backward-compatible in general. • Older Knowledge Scripts (v6.2 and earlier) are **no longer supported**. Minor upgrade of Web Recorder. • New WebTransaction Knowledge Scripts not backward-compatible in general. • Older Knowledge Scripts (v6.2 and earlier) are **no longer supported**. • All backlevel WebTransaction Knowledge Scripts (v6.2 and earlier) must be upgraded or re-recorded. Minor upgrade of URL Check Recorder. • New URLCheck Knowledge Scripts not backward-compatible. • Older Knowledge Scripts (v6.2 and earlier) are **no longer supported**. • All backlevel URLCheck Knowledge Scripts (v6.2 and earlier) must be upgraded or re-recorded.
ResponseTime for Web 7.1 (Web-download package)	Upgrade of all Knowledge Scripts. • FTP, InternetMail, NNTPConnect, and SMTPConnect Knowledge Scripts not backward-compatible in general. • Older Knowledge Scripts (v6.2 and earlier) are **no longer supported**. Major upgrade of Web Recorder. • New WebTransaction Knowledge Scripts not backward-compatible in general. • Older Knowledge Scripts (v6.2 and earlier) are **no longer supported**. • All backlevel WebTransaction Knowledge Scripts (v6.2 and earlier) must be upgraded or re-recorded. Major upgrade of URL Check Recorder. • New URLCheck Knowledge Script not backward-compatible. • Older Knowledge Scripts (v6.2 and earlier) are **no longer supported**. • All backlevel URLCheck Knowledge Scripts (v6.2 and earlier) must be upgraded or re-recorded.

79.2 CheckURL

Use this Knowledge Script to monitor the availability and performance of a single URL, including measuring connection and download time and validating and searching for text, links, and objects.

The CheckURL Knowledge Script cannot be edited using the URL Check Recorder. This Knowledge Script monitors a single URL, and you can view or modify all available parameter options in the Knowledge Script Values tab, using either the Control Center or Operator Console. To create a custom Knowledge Script that can monitor multiple URLs, use the URL Check Recorder to create a URLCheck Knowledge Script.

NOTE: You cannot use the Report_Web-RT_URLCheck Knowledge Script to generate reports out of data from the CheckURL Knowledge Script. To report on data from the CheckURL Knowledge Script, use the default reports provided with AppManager. For more information about running default reports, see the Control Center User Guide for AppManager.

79.2.1 Resource Object

CheckURL

79.2.2 Default Schedule

The default interval for these Knowledge Scripts is **Every hour**.

79.2.3 Setting Parameter Values

Set the following parameters as needed.

Description	How to Set It
URL	Specify the URL you want to verify.
Description	Specify the logical description or label of the checked URL.
Logical Target	Specify the identifier to use to enable retrieval of data streams by AppManager Analysis Center v2.0 and higher. By default, either the Label or the Link text for the URL.
General	
Username	Specify the URL authentication username.
Password	Specify the URL authentication password. It is automatically encrypted.
Proxy	
Proxy Server (host:port)	Specify the name of the proxy server computer and port to use, if necessary in your environment, using this format: `host:port`.
User ID	Specify a proxy server username if required. Specify the proxy server username using the format: `username` or `domain\username`.
Password	Specify the proxy server authentication password, if necessary.

Description	How to Set It
Header	Enter a header needed for a function executed on the server. Specify the header using the format: `value:parameter`. AppManager only supports one header.
Post Data	Enter any additional data that the receiving page needs to properly process the request, as in an HTTP Get function. Specify the post data using the format: `value1=parameter&value2=parameter2`. This parameter is optional.
Allow auto-redirects?	Select the **Yes** check box to allow the checked URL to auto-redirect. By default, redirects are allowed. By default, when checking the status of a URL that is redirected, both the original URL and all subsequently redirected URLs are verified, and status is returned for all URLs. This option can be disabled by disabling this parameter.
Uses header with redirections?	Select **Yes** to enable the passing of the header information when this URL is redirected.The default is unselected.
Uses post data with redirections?	Select **Yes** to enable the passing of post data information when this URL is redirected. The default is unselected.
Raise event on redirection?	Select the **Yes** check box to raise an event when the checked URL redirects to one or more subsequent URLs. By default, events are raised.
Number of duplicate redirections before considered looping	Specify the number of times a URL can be redirected to the same location before AppManager raises an event for looping. The default is 1 time. **Notes** • If you set the value to 0, the first duplicate redirection generates a 499 failure. The URL appears once on the detail table. • You can set this value per URL and can modify the value from a running job. • If you keep receiving 499 failures, try increasing this value by 1 and running the job again.
Event severity when URL is redirected	Set the event severity level, from 1 to 40, to indicate the importance of the event raised when the checked URL redirects to one or more subsequent URLs. The default severity level is 20 (yellow event indicator).
Redirect event title	A title for the event raised when the checked URL redirects to one or more subsequent URLs. This field accepts the following substitution variables: • `[l]` – Substitute the URL address being measured. The URL corresponds to the value you entered in the URL parameter. • `[d]` – Substitute the URL description. The description corresponds to the value you entered in the **Description** parameter. Default is “URL [l] Redirected: [d].”
Details to be included in events	Set to Failure or All. • Failure – only includes details for failure events or matched event criteria • All – includes details for all results Default is Failure.
Availability	

Description	How to Set It
Collect data?	Select the **Yes** check box to collect data on the availability of the URL. By default, data is collected.
Details to be saved with data point	Set to Failure, Success, All, or None. • Failure – Only includes details for failure events or matched event criteria. • Success – Only includes successful results. • All – Includes details for all results. • None – Includes no data details. Default is None.
Data stream format	Select the data stream format for the Availability data stream. Previous versions of AppManager ResponseTime for Web used a 0 ("not available") or 1 ("available") format to indicate availability. You now have the option to use a 0 ("not available") or 100 ("available") format. The default value is 0-100.
Data stream legend	A legend for the data stream that measures the availability status of the URL. This field accepts the following substitution variables: • `[l]` – Substitute the URL address being measured. The URL corresponds to the value you entered in the URL parameter. • `[d]` – Substitute the URL description. The description corresponds to the value you entered in the **Description** parameter. Default is “Availability for URL [d]”. The URL variable [l] is not included by default, but you can add the variable anywhere within the legend string. **NOTE:** As a best practice, use URL index variables for Knowledge Scripts that monitor multiple URLs. The variables ensure event and data stream legends for each monitored URL are unique. If you remove URL indexes, it is recommended that you do so only for Knowledge Scripts that monitor a single URL.
Raise event on failure	Select the **Yes** check box to raise an event when either the Internet connection or the loading of the base page fails. By default, an event is raised.
Event severity when URL fails	Set the event severity level, from 1 to 40, to indicate the importance of the event raised when a check of the URL fails. Default is 10 (red event indicator).

Description	How to Set It
Failure event title	A title for the event raised when the checked URL returns a status code associated with link failure. For more information, see “Status Code and Status Description” on page 4586. This field accepts the following substitution variables: • `[l]` – Substitute the URL address being measured. The URL corresponds to the value you entered in the URL parameter. • `[d]` – Substitute the URL description. The description corresponds to the value you entered in the **Description** parameter. Default is “URL [d] Failed”. The URL variable [l] is not included by default, but you can add the variable anywhere within the legend string. **NOTE:** As a best practice, use URL index variables for Knowledge Scripts that monitor multiple URLs. The variables ensure event and data stream legends for each monitored URL are unique. If you remove URL indexes, it is recommended that you do so only for Knowledge Scripts that monitor a single URL.
Availability = 0 if Validation in error or Search Criteria met	Set to **Yes** to change Availability to **0** if the URL cannot be validated or if a specific text string is not found.
Measure Processing Time	
Collect data?	Select the **Yes** check box to collect data on the processing time taken for this Knowledge Script to run. By default, data is not collected.
Data stream legend	A legend for the data stream that measures the processing time for the URL. This field accepts the following substitution variables: • `[l]` – Substitute the URL address being measured. The URL corresponds to the value you entered in the URL parameter. • `[d]` – Substitute the URL description. The description corresponds to the value you entered in the **Description** parameter. Default is “Processing Time for URL [d]”. The URL variable [l] is not included by default, but you can add the variable anywhere within the legend string. **NOTE:** As a best practice, use URL index variables for Knowledge Scripts that monitor multiple URLs. The variables ensure event and data stream legends for each monitored URL are unique. If you remove URL indexes, it is recommended that you do so only for Knowledge Scripts that monitor a single URL.
Threshold – Maximum processing time	Set the maximum time allowed to perform all operations, including generating data and events, before an event is raised. The default is 180 seconds.
Raise event if threshold exceeded?	Select the **Yes** check box to raise events if the overall time to process the job exceeds the threshold. By default, events are not raised.
Event severity when processing time threshold exceeded	Set the event severity level, from 1 to 40, to indicate the importance of the event when the overall processing time threshold is exceeded. The default severity level is 20 (blue event indicator).

Description	How to Set It
Processing Time Event title	A title for the event raised when the processing time for the checked URL exceeds the value you set for the **Threshold – Maximum overall processing time** parameter. This field accepts the following substitution variables: • `[l]` – Substitute the URL address being measured. The URL corresponds to the value you entered in the URL parameter. • `[d]` – Substitute the URL description. The description corresponds to the value you entered in the **Description** parameter. Default is "Processing Time Threshold exceeded for URL [d]". The URL variable [l] is not included by default, but you can add the variable anywhere within the legend string. **NOTE:** As a best practice, use URL index variables for Knowledge Scripts that monitor multiple URLs. The variables ensure event and data stream legends for each monitored URL are unique. If you remove URL indexes, it is recommended that you do so only for Knowledge Scripts that monitor a single URL.
Measure Connection Time	Select the **Yes** check box to enable connection time measurement. By default, measurement is not enabled.
Collect data?	Select the **Yes** check box to collect data on the amount of time it took to connect to the page represented by the URL and download the first byte of information. By default, data is not collected.
Include DNS Lookup time (if applicable)?	Set to **Yes** to include the time taken to resolve the URL by means of a DNS server in the connection-time measurement. Default is No.
Data stream legend	A legend for the data stream that totals the connection times: the time it takes to connect to the URL and download a single byte of information. This field accepts the following substitution variables: • `[l]` – Substitute the URL address being measured. The URL corresponds to the value you entered in the URL parameter. • `[d]` – Substitute the URL description. The description corresponds to the value you entered in the **Description** parameter. Default is "Connection Time for URL [d]". The URL variable [l] is not included by default, but you can add the variable anywhere within the legend string.
Threshold – Maximum connection time	Specify the maximum allowed connection time, in milliseconds. This parameter is the time taken to connect to the checked URL and to download the first byte of information from the associated Web page. If the time taken to connect exceeds this threshold, an event is raised. Default is 1000 milliseconds.
Raise event if threshold exceeded?	Set to **Yes** to raise an event when the amount of time to connect to the specified Web page and download a single byte exceeds the Connection Threshold. Default is Yes.
Event severity when connection time threshold is exceeded	Set the event severity level for the **Measure connection time** threshold from 1 to 40 to indicate the importance of the event raised when the URL download threshold is exceeded. Default severity level is 21 (blue event indicator).

Description	How to Set It
Connection Time Event title	A title for the event raised when the connection time for the URL exceeds the value you set for the **URL connection timeout** parameter. This field accepts the following substitution variables: • `[l]` – Substitute the URL address being measured. The URL corresponds to the value you entered in the URL parameter. • `[d]` – Substitute the URL description. The description corresponds to the value you entered in the **Description** column of the URLs table. Default is "URL [d] Connection Time threshold exceeded". The URL variable [l] is not included by default, but you can add the variable anywhere within the legend string. **NOTE:** As a best practice, use URL index variables for Knowledge Scripts that monitor multiple URLs. The variables ensure event and data stream legends for each monitored URL are unique. If you remove URL indexes, it is recommended that you do so only for Knowledge Scripts that monitor a single URL.
Connection timeout	Specify a connection timeout in seconds. Default is 10 seconds. Modify this value if connections and downloads are timing out. In most cases, you get an error code of 12002 for timeout conditions.
Measure Download Time	Select the **Yes** check box to enable download time measurement. By default, measurement is not enabled.
Collect data?	Select the **Yes** check box to collect data on the amount of time it takes to download the HTML and associated objects for the checked URL. By default, data is not collected.
Data stream legend	A legend for the data stream that totals the time it takes to download the HTML and associated objects for the checked URL. This field accepts the following substitution variables: • `[l]` – Substitute the URL address being measured. The URL corresponds to the value you entered in the URL parameter. • `[d]` – Substitute the URL description. The description corresponds to the value you entered in the **Description** parameter. Default is "Download Time for URL [d]". The URL variable [l] is not included by default, but you can add the variable anywhere within the legend string. **NOTE:** As a best practice, use URL index variables for Knowledge Scripts that monitor multiple URLs. The variables ensure event and data stream legends for each monitored URL are unique. If you remove URL indexes, it is recommended that you do so only for Knowledge Scripts that monitor a single URL.
Threshold – Maximum download time	Specify the maximum allowed download time, in milliseconds. This parameter is the time taken to download the HTML and associated objects for the checked URL. If the time taken to download exceeds this threshold, an event is raised. Default is 3000 milliseconds.
Raise event if threshold exceeded?	Set to Yes to raise an event if the download time for the checked URL exceeds the threshold. Default is Yes.

Description	How to Set It
Event severity when download time threshold exceeded	Set the event severity level for the **Measure download time** threshold from 1 to 40 to indicate the importance of the event raised when the URL download threshold is exceeded. Default severity level is 21 (blue event indicator).
Download Time Event title	A title for the event raised when the download time for the URL exceeds the value you set for the **URL download timeout** parameter. This field accepts the following substitution variables: • `[l]` – Substitute the URL address being measured. The URL corresponds to the value you entered in the URL parameter. • `[d]` – Substitute the URL description. The description corresponds to the value you entered in the **Description** parameter. Default is "URL [d] Download Time threshold exceeded". The URL variable [l] is not included by default, but you can add the variable anywhere within the legend string. **NOTE:** As a best practice, use URL index variables for Knowledge Scripts that monitor multiple URLs. The variables ensure event and data stream legends for each monitored URL are unique. If you remove URL indexes, it is recommended that you do so only for Knowledge Scripts that monitor a single URL.
Download timeout	Specify a download timeout in seconds. Default is 30 seconds.
Validate All Links	Select the **Yes** check box to enable link validation. By default, validation is not enabled.
Raise event if link validation is in error?	Select **Yes** or **No** to determine whether the Knowledge Script should raise an overall event if any one of the links it checks fails to validate. Link validation failures are defined as links that return HTTP status codes in the 400s or 500s, WinHTTP error codes (12xxxx), or Windows Sockets error codes (11xxxx). The default is Yes. For more information, see "Status Code and Status Description" on page 4586.
Event severity when link validation is in error	Set the event severity level when a link on a page has an HTTP status code or any WinHTTP errors, to indicate the importance of the event. Default is 22 (blue event indicator). For more information, see "Status Code and Status Description" on page 4586.

Description	How to Set It
Validate Links Event title	A title for the event raised when a link fails to validate. This field accepts the following substitution variables: • `[l]` – Substitute the URL address being measured. The URL corresponds to the value you entered in the URL parameter. • `[d]` – Substitute the URL description. The description corresponds to the value you entered in the **Description** parameter. Default is "URL [d] Validate Link Failure". The URL variable [l] is not included by default, but you can add the variable anywhere within the legend string. **NOTE:** As a best practice, use URL index variables for Knowledge Scripts that monitor multiple URLs. The variables ensure event and data stream legends for each monitored URL are unique. If you remove URL indexes, it is recommended that you do so only for Knowledge Scripts that monitor a single URL.
Validate All Objects	Use these parameters to determine whether to collect data and raise events on object validation. Select the **Yes** check box to enable object validation. By default, validation is not enabled.
Raise event if object validation is in error?	Select **Yes** or **No** to determine whether the Knowledge Script should raise an overall event any time an object fails to validate. Object validation failures are defined as objects that return HTTP status codes in the 400s or 500s, WinHTTP error codes (12xxxx), or Windows Sockets error codes (11xxxx). The default is Yes. For more information, see "Status Code and Status Description" on page 4586.
Event severity when object validation is in error	Set the event severity level when an object on a page has an HTTP status code or any WinHTTP errors, to indicate the importance of the event. Default is 22 (blue event indicator). For more information, see "Status Code and Status Description" on page 4586.
Validate Objects Event title	A title for the event raised when a link fails to validate. This field accepts the following substitution variables: • `[l]` – Substitute the URL address being measured. The URL corresponds to the value you entered in the URL parameter. • `[d]` – Substitute the URL description. The description corresponds to the value you entered in the **Description** parameter. Default is "URL [d] Validate Object Failure." The URL variable [l] is not included by default, but you can add the variable anywhere within the legend string.
Search String	Select the **Yes** check box to enable string searching. By default, string searching is not enabled.
String to search	Specify string for search. Specify only 1 string.
Case Sensitive?	If enabled, the search is case-sensitive.

Description	How to Set It
Raise event if string is	Specify whether to raise an overall event when a string meets a selected condition. You can set the Search Strings URL Property for the checked URL, which instructs URL Check Recorder to search for a particular string on the page. The default is “Not Found”.
Event severity when search string criteria are met	Set the event severity level when a string is Found or Not Found, from 1 to 40, to indicate the importance of the event. Default is 25 (blue event indicator).
Search String Event title	A title for the event raised when any specified search string value is met. This field accepts the following substitution variables: • `[l]` – Substitute the URL address being measured. The URL corresponds to the value you entered in the URL parameter. • `[d]` – Substitute the URL description. The description corresponds to the value you entered in the **Description** parameter. Default is “URL [d] Search String Criteria Met”. The URL variable [l] is not included by default, but you can add the variable anywhere within the legend string.
Search Link	Select the **Yes** check box to enable link searching. By default, link searching is not enabled.
Link to search	Specify link for search. Specify only 1 link.
Raise event if link is	Specify whether to generate an event when the specified links are all "Found" or "Not Found". The default is “Not Found”.
Event severity when search link criteria are met	Set the event severity level when a link is Found or Not Found, from 1 to 40, to indicate the importance of the event. Default is 25 (blue event indicator).
Search Link Event title	The title of the event raised when the specified search link value is met. This field accepts the following substitution variables: • `[l]` – Substitute the URL address being measured. The URL corresponds to the value you entered in the URL parameter. • `[d]` – Substitute the URL description. The description corresponds to the value you entered in the **Description** parameter. The default is “URL [d] Search Link Criteria Met”. The URL variable [l] is not included by default, but you can add the variable anywhere within the legend string. **NOTE:** As a best practice, use URL index variables for Knowledge Scripts that monitor multiple URLs. The variables ensure event and data stream legends for each monitored URL are unique. If you remove URL indexes, it is recommended that you do so only for Knowledge Scripts that monitor a single URL.
Search Object	Select the **Yes** check box to enable object searching. By default, object searching is not enabled.
Object to search	Specify object for search. Specify only 1 object.
Raise event if object is	Specify whether to raise an event when the specified objects are all "Found" or "Not Found". The default is “Not Found”.
Event severity when search object criteria are met	Set the event severity level when an object is Found or Not Found, from 1 to 40, to indicate the importance of the event. Default is 25 (blue event indicator).

Description	How to Set It
Search Object Event title	The title of the event raised when the specified search object value is met. This field accepts the following substitution variables: • `[l]` – Substitute the URL address being measured. The URL corresponds to the value you entered in the URL parameter. • `[d]` – Substitute the URL description. The description corresponds to the value you entered in the **Description** parameter. The default is “URL [d] Search ObjectCriteria Met”. The URL variable [l] is not included by default, but you can add the variable anywhere within the legend string. **NOTE:** As a best practice, use URL index variables for Knowledge Scripts that monitor multiple URLs. The variables ensure event and data stream legends for each monitored URL are unique. If you remove URL indexes, it is recommended that you do so only for Knowledge Scripts that monitor a single URL.

79.2.4 Status Code and Status Description

For the verified URL, the status code and status description from the Web server are returned. This also applies to any redirected URLs.

URLs that return `1xx`, `2xx` and `3xx` HTTP Status codes are considered successes, while `4xx` or `5xx` HTTP Status codes, WinHTTP error codes (`12xxxx`), or Windows Sockets error codes (`11xxxx`) are considered failures. For more information, see .

For more information about HTTP status codes and Windows Socket error codes, see the following references.

Category	Link
HTTP status codes	http://msdn2.microsoft.com/en-us/library/Aa384325.aspx
WinHTTP error codes	http://msdn2.microsoft.com/en-us/library/Aa383770.aspx
Windows Sockets error codes	http://msdn2.microsoft.com/en-us/library/ms740668.aspx

79.3 FTP

Use this Knowledge Script to check the availability of an FTP site, and verify that a file can be downloaded from the site. In addition, you can use this Knowledge Script to compare the contents of a file downloaded from the FTP site with a file on a local computer.

This Knowledge Script raises an event if any of the following conditions occur:

- The specified FTP site does not respond to the FTP connection request.
- A specified FTP file cannot be downloaded from the site.
- The local file cannot be located.
- The contents of a downloaded FTP file are different from the contents of a specified local file.

If you choose to compare the contents of a downloaded file with the contents of a local file, the Knowledge Script downloads the entire file from the FTP site in both binary and ASCII formats and compares both formats against the local file. An event raised if differences are found between the files after the second comparison. The downloaded file is saved in memory and is never placed on disk. The size of the file to download must be 20 MB or fewer.

The FTP Knowledge Script supports the use of different port numbers, Passive FTP (PASV) for use through a firewall, and connections through a proxy server.

You can select where some of the possible events are displayed in the Operator Console TreeView or Control Center Console Server view. This event proxying feature is useful in Control Center Service Map views. It is not supported for jobs that are started in the Operator Web Console. See the description of the **Event on** parameter in the following table.

If you choose to collect data, a data stream for availability is generated, with one of the following values:

- 1 or 100 = the FTP server responded to the connection request, or
- 0 = the FTP server did not respond.

As discussed previously, this Knowledge Script potentially performs as many as four discrete actions. If any one of the following actions fails, the entire ResponseTime transaction fails, and the Availability data point is 0:

- Connection to the FTP server
- File download
- Opening local file
- Comparing downloaded file to local file

79.3.1 Resource Object

FTP

79.3.2 Default Schedule

The default interval for this Knowledge Script is Every 15 minutes.

79.3.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Availability	
Collect data for availability?	Select the **Yes** check box to collect availability data for graphs and reports. If enabled, the Knowledge Script returns: • 1 or 100 = the FTP server responded to the connection request. • 0 = the FTP server did not respond. By default, data is collected.
Data stream format	Select the data stream format for the Availability data stream. Previous versions of AppManager ResponseTime for Web used a 0 ("not available") or 1 ("available") format to indicate availability. You now have the option to use a 0 ("not available") or 100 ("available") format. The default value is 0-100.
Raise event if transaction fails?	Select the **Yes** check box to raise an event when the FTP server cannot be contacted or the transaction fails. By default, an event is raised.
Event severity when transaction fails	If events are enabled, set the event severity level, from 1 to 40, to indicate the importance of the event. Default is 5.
File Download	
Full path and filename to download	Specify the path to the file you want to download from the FTP site, using forward slashes (/) as delimiters. For example: `ftpforms/CAform22.zip` **Notes** You only need to specify the directory in which the file is located and the name of the file. You should not enter a complete, fully qualified URL, for example, `ftp://mysite.com/ftpforms/CAform22.zip`. If you enter a directory path to a local file for the **Full path and filename of local file to compare** parameter, the Knowledge Script can compare the contents of the downloaded file with those of the local file and report any discrepancies. The size of the file to download is limited to 20 MB.

Full path and filename of local file to compare	Specify the path to the local file that you want to use for comparison, using backslashes (\) as delimiters. You can specify a standard path or UNC path. For example:
	`C:\CAforms\CAform22.doc (standard path)`
	`\\CAforms\CAform22.doc (UNC path)`
	This field is case-sensitive.
	Any discrepancies between the files are reported in the Event Details.

Download Time	
Collect data for download time?	Select the **Yes** check box to collect response-time data for graphs and reports. By default, data is collected.
Threshold – Maximum download time (seconds)	Specify the maximum response time in seconds. When response time exceeds this value, an event is raised. The event message contains a breakdown of the total response time. The default is 5 seconds.
Raise event if threshold is exceeded?	Select the **Yes** check box to raise an event when the response-time threshold is exceeded. By default, events are raised.

Description	How to Set It
Event severity when threshold is exceeded	Set the event severity level, from 1 to 40, to indicate the importance of the event. Default is 15.

FTP Server	Specify the path to the FTP server that you want to monitor. For example:
	`ftp://ftp.support.com`
	or
	`ftp.support.com`
	NOTE: You can only enter the path to the FTP server itself. You cannot enter a path to a directory on a server, such as `ftp.support.com/files`.
	You can also click **Browse [...]** to select from a list of available FTP servers. The server you select must already be in the TreeView.
	In addition, you can pass a port number following the FTP servername, for example:
	`ftp://ftp.support.com:2100`.)
	If you are setting the **Event on** parameter, the **FTP Server** parameter lets you select the server where the event appears in your console.

Connect using Passive Mode?	Select the **Yes** check box to enable Passive FTP. Passive FTP may be required if the client or server are behind a firewall. By default, Passive FTP is enabled.
Event on	Select the TreeView location where events should be displayed. Select either: • **Agent** – The client computer in the response-time tests. This is the default. • **Server** – The FTP server being tested; see the **FTP Server** parameter. • **Both** – The event is shown in two locations in the TreeView. **Notes** This setting does not apply to events related to the Knowledge Script itself, such as Knowledge Script failure or initialization problems. Such events are always displayed on the computer where the job ran. You must select `Agent` when starting jobs in the Operator Web Console. If you select `Server`, no events are generated. If you select `Both`, an event is only shown on the agent.
FTP Logon	
Username	Specify the username to use when connecting to the FTP site that you want to monitor. Type the name exactly as you would when using it to access the FTP site.
Password	Specify the password to use when connecting to the FTP site that you want to monitor. Type the password exactly as you would when using it to access the FTP site. **NOTE:** Password entries are limited to a maximum of 32 characters.
Proxy Settings	
Server name	Specify the name of the proxy server computer and port to use, if necessary in your environment, using this format: `proxyserver:port` **NOTE:** When using a proxy server, this script cannot determine the size of the remote file in advance. If the file size exceeds 20 MB, the FTP file transfer may time out.

Description	How to Set It
Username	Specify a proxy server username if required. Specify the proxy server username using the format: `username` or `domain\username`.
Password	Specify a proxy server password if required.

79.4 NNTPConnect

Use this Knowledge Script to monitor the availability of an NNTP server. When the specified NNTP server does not respond to a connection request to the NNTP port (port 119), an event is raised.

You can select where some of the possible events are displayed in the Operator Console TreeView or Control Center Console Server view. This event proxying feature is useful in Control Center Service Map views. It is not supported for jobs that are started in the Operator Web Console. See the description of the **Event on** parameter in the following table.

If you choose to collect data, a data stream for Availability is generated, with one of the following values:

- 1 or 100 = the NNTP server responded to the connection request, or
- 0 = the NNTP server did not respond.

  The Availability data point is an indication of whether the test succeeded or failed. If a connection to the NNTP server cannot be established, the Availability data point is 0, which indicates not available or not successful.

79.4.1 Resource Object

News (NNTP) server.

79.4.2 Default Schedule

The default interval for this Knowledge Script is Every 15 minutes.

79.4.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Availability	
Collect data for availability?	Select the **Yes** check box to collect availability data for graphs and reports. If enabled, the Knowledge Script returns: • 1 or 100 = the NNTP server responded to the connection request. • 0 = the NNTP server did not respond. By default, data is collected.
Data stream format	Select the data stream format for the Availability data stream. Previous versions of AppManager ResponseTime for Web used a 0 ("not available") or 1 ("available") format to indicate availability. You now have the option to use a 0 ("not available") or 100 ("available") format. The default value is 0-100.
Raise event if connection fails?	Select the **Yes** check box to raise events. By default, events are raised.
Event severity when connection fails	Set the event severity level, from 1 to 40, to indicate the importance of the event. Default is 5 (red event indicator).

Description	How to Set It
NNTP Server	Specify the name of the NNTP server that you want to monitor. For example, `msnews.microsoft.com` You can also click **Browse [...]** to select from a list of available NNTP servers. The server you select must already be in the TreeView. In addition, you can pass a port number following the NNTP servername. For example, `msnews.microsoft.com:563`. If you are setting the **Event on** parameter, the **NNTP Server** parameter lets you select the server where the event appears in your console.
Event on	Select the TreeView location where events should be displayed. Select either: • **Agent** – The client computer in the response-time tests. This is the default. • **Server** – The NNTP server being tested; see the **NNTP Server** parameter. • **Both** – The event is shown in two locations in the TreeView. **Notes** This setting does not apply to events related to the Knowledge Script itself, such as Knowledge Script failure or initialization problems. Such events are always displayed on the computer where the job ran. You must select `Agent` when starting jobs in the Operator Web Console. If you select `Server`, no events are generated. If you select `Both`, an event is only shown on the agent.

79.5 ReceiveInternetMail

Use this Knowledge Script to monitor the availability and the response time taken to receive an Internet mail message using POP3 protocol.

You can run this script as "Interactive User." This setting *requires* a user to be physically logged into the computer for the test to run. You might want to do this in environments where a firewall is preventing access to an Active Directory domain controller, or where the test computer is part of a workgroup and not part of a domain. With this feature, the user is not validated, so the test can proceed despite the lack of access to the domain. To run as interactive user, type "`Interactive User`" for the **Run As Username** parameter, and leave the **Password** and **Domain** parameters blank.

79.5.1 Collecting Data

If you choose to collect data, this Knowledge Script generates the following data streams:

- **Response time**
  - **Overall response time**. The information returned by this data stream is also saved with the data point, and can be viewed by double-clicking the data point in the Graph Pane or Chart Console.
  - **Response-time Breakdown**. If enabled as separate parameters, up to 2 response-time breakdown data streams. These are individual data points for the different parts of the Knowledge Script transaction that are timed. For more information, see "Setting Parameter Values" on page 4595.
- **Availability:** Returns one of the following values:
  - 1 or 100 = the transaction was successful
  - 0 = the transaction was not successful

  The Availability data point is an indication of whether the test succeeded or failed. If, for example, a connection to the POP3 mail server was established but the message was never received, the Availability data point is 0, which indicates not available or not successful.

An event is raised whenever one of the following occurs:

- A threshold that you have specified as an event parameter is exceeded.
- The Web-RT InternetMail engine cannot be initialized. An initialization error is generated, but an Availability or Response Time data stream is not generated.
- The transaction does not complete successfully. A transaction error is generated. Only an Availability data stream is generated, with a value of 0.

You can select where some of the possible events are displayed in the Operator Console TreeView or Control Center Console Server view. This event proxying feature is useful in Control Center Service Map views. It is not supported for jobs that are started in the Operator Web Console. See the description of the **Event on** parameter in the following table.

79.5.2 Resource Object

Internet Mail

79.5.3 Default Schedule

The default interval for this Knowledge Script is Every 15 minutes.

79.5.4 Setting Parameter Values

Set the following parameters as needed

Description	How to Set It
Availability	
Collect data for availability?	Select the **Yes** check box to collect availability data for graphs and reports. If enabled, the Knowledge Script returns: • 1 or 100 = the Internet mail server responded to the connection request. • 0 = the Internet mail server did not respond. By default, data is collected.
Data stream format	Select the data stream format for the Availability data stream. Previous versions of AppManager ResponseTime for Web used a 0 ("not available") or 1 ("available") format to indicate availability. You now have the option to use a 0 ("not available") or 100 ("available") format. The default value is 0-100.
Raise event if transaction fails?	Select the **Yes** check box to raise events. By default, events are raised.
Event severity when transaction fails	Set the event severity level, from 1 to 40, to indicate the importance of the event. Default is 5 (red event indicator).
Response Time	
Collect data for response time?	Select the **Yes** check box to collect data for graphs and reports. By default, data is collected.
Threshold – Maximum response time (seconds)	Specify the maximum response time in seconds. When response time exceeds this value, an event is raised. The event message contains a breakdown of the total response time. The default is 15 seconds.
Raise event if threshold is exceeded?	Select the **Yes** check box to raise an event when the threshold is exceeded. By default, events are raised.
Event severity when threshold is exceeded	Set the event severity level, from 1 to 40, to indicate the importance of the event. Default is 15 (yellow event indicator). If you disable Response Time events, this value is ignored.
Response Time Breakdown	
Collect data for connecting to POP3 server?	Select the **Yes** check box to collect a separate response-time data stream for the time taken to connect to the POP3 server. By default, separate response-time data streams are not collected.
Collect data for receiving message?	Select the **Yes** check box to collect a separate response-time data stream for the time taken to receive the test Internet Mail message. By default, separate response-time data streams are not collected.
POP3 Server Settings	

Description	How to Set It
Server name	Specify the name of the POP3 server, or click **Browse [...]** to select from a list of available servers. The server you select must already be in the TreeView. If you are setting the **Event on** parameter, the **Target computer** parameter lets you select the server where the event appears in your console.
Server port number	Specify the port number of the POP3 server. Default is 110.
Username	Specify the POP3 username of the client on which the Knowledge Script is to run.
Password	Specify the POP3 password for the associated POP3 user name.
Leave message on server?	Select the **Yes** check box to leave the message on the POP3 server. Clear the box to delete the message from the server. By default, messages are left on the server.
Event on	Select the TreeView location where events should be displayed. Select either: • **Agent** – The client computer in the response-time tests. This is the default. • **Server** – The mail server being tested; see the **Server name** parameter. • **Both** – The event is shown in two locations in the TreeView. **Notes** This setting does not apply to events related to the Knowledge Script itself, such as Knowledge Script failure or initialization problems. Such events are always displayed on the computer where the job ran. You must select `Agent` when starting jobs in the Operator Web Console. If you select `Server`, no events are generated. If you select `Both`, an event is only shown on the agent.
Run As	
Username	Specify the user ID associated with a specific user who has the required permissions to run this application. Leave the **Password** and **Domain** parameters blank if you specify "`Interactive User`".
Password	Specify the password associated with this user that is required to log on to the network and run the application.
Domain	Specify the domain name of the domain you are logging onto. Required.
Administrators group on managed client	Specify the name of the Administrators Group on the managed client. Typically, this name is "Administrators", except on some foreign-language operating systems. Default is "Administrators".
Timeouts	
Job timeout	Set the timeout value, from 1 to 900 seconds, to determine the maximum time allowed to process a job before it's aborted. When an Web-RT Knowledge Script job runs, a job timer is started. If the transaction takes longer than the Job timeout, the transaction is stopped and a "Job Timeout" event is raised. The default is 120 seconds.

Description	How to Set It
Queue timeout	Set the timeout value, from 1 to 1200 seconds, to determine how long a job can wait for resources before it's aborted. Multiple simultaneous Web-RT Knowledge Script jobs must wait for a token to run. If no token is available for a job you're trying to run, the job is added to the queue and starts a queue timer. When the Queue Timeout for a job expires, the job does not run, a "Queue Timeout" event is raised, and the job is moved to the end of the queue. The default is 300 seconds.
Connection timeout	Set the connection timeout value to determine how long a job can wait for a connection to the POP3 and SMTP servers before the job is aborted. The default is 30 seconds.

79.6 Report_Web-RT_Mail

Use this Knowledge Script to generate a report detailing availability and response time for the following Web-RT Knowledge Scripts:

- ReceiveInternetMail
- SendAndReceiveInternetMail
- SendInternetMail

This report contains two graphs and tables identifying availability and overall response time for a particular Knowledge Script.

79.6.1 Resource Object

Web-RT

79.6.2 Default Schedule

The default schedule is Run once.

79.6.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Data source	
Knowledge Script for report	Select the Knowledge Script to report on. Click **Browse [...]** to show the Select a Knowledge Script dialog box. Highlight a Web-RT Knowledge Script from the **Knowledge Script Name** list and click **Finish** to select it.
Web-RT client(s)	Select the Web-RT clients. Click **Browse [...]** to show the Select View(s) and a filter dialog box. From the **View(s)** list, select up to 25 views. Your subsequent selections are limited to computers or server groups that are visible in the selected views. Select one of the Filters options: • **View:** Includes all computers in the views you selected. • **Computer:** Select from individual computers in the views you selected. • **Server Group:** Select from server groups in the views you selected. Selecting a server group includes all computers in that group.
Mail Server or “All”	Type the name of the Mail Server, or type “All” to designate all computers as Mail Servers. The default is “All”.
Select time range	In the Select Date/Time Range dialog box, set specific start and end report information dates, good for historical or ad hoc reports, or a sliding range, the default, that sets the time range of data to include in the report. This option is useful for reports running on a regular schedule and is the default.

Description	How to Set It
Select peak weekday(s)	Click **Browse [...]** to see the Select Peak Weekday(s) dialog box. Press **Shift** and click on days to select a contiguous range of days, or **Ctrl+Click** to select non-contiguous days.
Aggregation by	Select the time unit by which to aggregate data. The default is Hour. Works in conjunction with the next field, Aggregation interval, which determines the number of units for one interval of data aggregation.
Aggregation interval	Select the interval units in which to aggregate data. The default is 1. For example, if you aggregate by the Hour and select 1 here, data is aggregated once every hour.
Report settings	
Include parameter card?	Select the Yes check box to include a table in the report that lists parameter settings for the report Knowledge Script. By default, the table is included.
Include Availability detail table?	Specify whether to display the Availability detail table as part of the report. By default, the table is included.
Include Availability chart?	Specify whether to display the Availability chart as part of the report. By default, the chart is included.
Threshold on Availability chart	Enter an integer for the availability, as a percent (%), to use as a threshold on the chart. Default is 0, or no threshold is displayed.
Include ResponseTime detail table?	Specify whether to display the ResponseTime detail table as part of the report. By default, the table is included.
Include ResponseTime chart?	Specify whether to display the ResponseTime chart as part of the report. By default, the chart is included.
Units for ResponseTime report	Select the response time unit, either the default, milliseconds, or seconds.
Threshold on Response Time chart (selected units)	Specify the time in the units specified in the previous parameters to use for the threshold indicator on the chart, or use the default of 0.0, for no threshold indicator is used.
Select chart style	Options in the Chart Settings dialog box set the appearance of the chart. The same parameters are used in both the availability and Response Time charts, if both are produced. Default is Ribbon.
Select output folder	In the Specify report folder/filename dialog box, enter an output filename and fill in the remote folder fields.
Add job ID to output folder name?	Specify whether to add a job ID to the output folder name.
Index-Report Title	In the Report Properties dialog box, configure report title settings.
Add time stamp to title	Specify whether to add a timestamp to the report title.
Event notification	
Generate event on success?	Specify whether an event is raised when a report is generated. By default, events are raised.
Severity level for report success	Set the severity level for a successful report. Default is 35 (magenta event indicator).
Severity level for report with no data	Set the severity level for a report with no data. Default is 25 (blue event indicator).
Severity level for report failure	Set the severity level for a report with no data. Default is 5 (red event indicator).

79.7 Report_Web-RT_Steps

Use this Report Knowledge Script to generate a report detailing response time for the transaction steps in WebTransaction Knowledge Scripts created with the Web Recorder extension.

To create this report, enable data collection for individual steps in the selected WebTransaction Knowledge Script. You can also set the *Step default value for "Collect Response Time Data?"* parameter to **Yes** to enable data collection for all steps on a global basis. Click **Settings > Options** and then click the **Knowledge Script** tab in Web Recorder to enable this parameter.

NOTE: This Knowledge Script only works with WebTransaction Knowledge Scripts that use the default step legends.

79.7.1 Resource Object

Web-RT

79.7.2 Default Schedule

The default schedule is Run once.

79.7.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Data source	
Web Transaction Script	Select the Knowledge Script to report on. Click **Browse [...]** to show the Select a Knowledge Script dialog box. Highlight a Web Transaction Knowledge Script from the Knowledge Script Name list and click **Finish** to select it.
Web-RT client(s)	Select the Web-RT clients. Click **Browse [...]** to show the Select View(s) and a filter dialog box. From the **View(s)** list, select from one to twenty-five views. Your subsequent selections are limited to computers or server groups that are visible in the selected views. Select one of the Filters options: • **View:** Includes all computers in the views you selected. • **Computer:** Select from individual computers in the views you selected. • **Server Group:** Select from server groups in the views you selected. Selecting a server group includes all computers in that group.
Select time range	In the Select Date/Time Range dialog box, set specific start and end report information dates, good for historical or ad hoc reports, or a sliding range, the default, that sets the time range of data to include in the report. This option is useful for reports running on a regular schedule and is the default.
Select peak weekday(s)	Click **Browse [...]** to see the Select Peak Weekday(s) dialog box. Press **Shift** and click on days to select a contiguous range of days, or **Ctrl+Click** to select non-contiguous days.

Description	How to Set It
Aggregation by	Select the time unit by which to aggregate data. Default is Hour. This works in conjunction with the next field, Aggregation interval, which determines the number of units for one interval of data aggregation.
Aggregation interval	Select the interval units in which to aggregate data. Default is 1. For example, if you aggregate by the Hour and select 1 here, data is aggregated once every hour.
Report settings	
Include parameter card?	Select the Yes check box to include a table in the report that lists parameter settings for the report Knowledge Script. By default, the table is included.
Include ResponseTime detail table?	Specify whether to display the ResponseTime detail table as part of the report. By default, the table is included.
Include ResponseTime chart?	Specify whether to display the ResponseTime chart as part of the report. By default, the chart is included.
Units for ResponseTime report	Select the response time unit, either the default, msec, or sec.
Threshold on ResponseTime chart (selected units)	Specify the time in the units specified in the previous parameters to use for the threshold indicator on the chart. The default is 0.0, or no threshold indicator.
Select chart style	Options in the Chart Settings dialog box set the appearance of the chart. The same parameters are used in both the availability and ResponseTime charts, if both are produced. Default is Bar_Stacked.
Select output folder	In the Specify Report Folder/Filename dialog box, enter an output filename and fill in the remote folder fields. Default is Web-RT_Steps_(Script Name)
Add job ID to output folder name?	Specify whether to add a job ID to the output folder name.
Index-Report Title	In the Report Properties dialog box, configure report title settings. Default is Web-RT_Steps:(Script Name)
Add time stamp to title	Specify whether to add a timestamp to the report title. By default, no timestamp is added.
Event notification	
Generate event on success?	Specify whether an event is raised when a report is generated. By default, events are raised.
Severity level for report success	Set the severity level for a successful report. Default is 35 (magenta event indicator).
Severity level for report with no data	Set the severity level for a report with no data. Default is 25 (blue event indicator).
Severity level for report failure	Set the severity level for a report with no data. Default is 5 (red event indicator).

79.8 Report_Web-RT_URLCheck

Use this Report Knowledge Script to generate a report of availability as a percentage for the URLCheck Knowledge Script.

This report shows overall availability for all URLs checked by a particular Knowledge Script.

NOTE: This Knowledge Script only works with URLCheck Knowledge Scripts that use the default legend names. In addition, this Knowledge Script does not work with the CheckURL Knowledge Script. To report on data from the CheckURL Knowledge Script, use the default reports provided with AppManager. For more information about running default reports, see the Control Center User Guide for AppManager.

Set the following parameters as needed:

Description	How to Set It
Data source	
URL Check Script	Select the Knowledge Script to report on. Click **Browse [...]** to show the Select a Knowledge Script dialog box. Highlight a Web Transaction Knowledge Script from the Knowledge Script Name list and click Finish to select it.
Web Client(s)	Enter a specific client computer, or type `All` to report on all client computers.
Select time range	In the Select Date/Time Range dialog box, set specific start and end report information dates, good for historical or ad hoc reports, or a sliding range, the default, that sets the time range of data to include in the report. This option is useful for reports running on a regular schedule and is the default.
Select peak weekday(s)	Click **Browse [...]** to see the Select Peak Weekday(s) dialog box. Press **Shift** and click on days to select a contiguous range of days, or **Ctrl+Click** to select non-contiguous days.
Aggregation by	Select the time unit by which to aggregate data. Default is Hour. This works in conjunction with the next field, Aggregation interval, which determines the number of units for one interval of data aggregation.
Aggregation interval	Select the interval units in which to aggregate data. Default is 1. For example, if you aggregate by the Hour and select 1 here, data is aggregated once every hour.
Report settings	
Include parameter card?	Select the **Yes** check box to include a table in the report that lists parameter settings for the report Knowledge Script. By default, the table is included.
Include Percent Available detail table?	Specify whether to display the Percent Available detail table as part of the report. By default, the table is included.
Include Percent Available chart?	Specify whether to display the Percent Available chart as part of the report. By default, the chart is included.
Threshold on Percent Available chart (selected units)	Enter an integer for the availability, as a percent (%), to use as a threshold on the chart. Default is 0, or no threshold is displayed.
Select chart style	Options in the Chart Settings dialog box set the appearance of the chart. The same parameters are used in both the availability and ResponseTime charts, if both are produced. Default is Ribbon.
Select output folder	In the Specify report folder/filename dialog box, enter an output filename and fill in the remote folder fields. The default is Web-RT_ Script Name>.

Description	How to Set It
Add job ID to output folder name?	Specify whether to add a job ID to the output folder name.
Index-Report Title	In the Report Properties dialog box, configure report title settings. Default is Web-RT_URLCheck:(Script Name).
Add time stamp to title	Specify whether to add a time stamp to the report title. By default, no timestamp is added.
Event notification	
Generate event on success?	Specify whether an event is raised when a report is generated. By default, events are raised.
Severity level for report success	Set the severity level for a successful report. Default is 35 (magenta event indicator).
Severity level for report with no data	Set the severity level for a report with no data. Default is 25 (blue event indicator).
Severity level for report failure	Set the severity level for a report with no data. Default is 5 (red event indicator).

79.9 Report_Web-RT_Web

Use this Report Knowledge Script to generate a report detailing availability and response time for the WebTransaction Knowledge Scripts created with the Web Recorder extension.

This contains two graphs and tables with Availability and overall Response Time for a particular Knowledge Script. For more information, see .

NOTE: This Knowledge Script only works with WebTransaction Knowledge Scripts that use the default legend names.

79.9.1 Resource Object

Web-RT

79.9.2 Default Schedule

The default schedule is Run once.

79.9.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Data source	
WebTransaction Script	Select the Knowledge Script to report on. Click **Browse [...]** to show the Select a Knowledge Script dialog box. Highlight a WebTransaction Knowledge Script from the **Knowledge Script Name** list and click **Finish** to select it.
Web-RT client(s)	Select the Web-RT clients. Click **Browse [...]** to show the Select View(s) and a Filter dialog box. From the **View(s)** list, select from 1 to 25 views. Your subsequent selections are limited to computers or server groups that are visible in the selected views. Select one of the Filters options: • **View:** Includes all computers in the views you selected. • **Computer:** Select from individual computers in the views you selected. • **Server Group:** Select from server groups in the views you selected. Selecting a server group includes all computers in that group.
Select time range	In the Select Date/Time Range dialog box, click **Browse [...]** to set specific start and end report information dates, good for historical or ad hoc reports, or a sliding range, the default, that sets the time range of data to include in the report. This option is useful for reports running on a regular schedule and is the default.
Select peak weekday(s)	Click **Browse [...]** to see the Select Peak Weekday(s) dialog box. Press **Shift** and click on days to select a contiguous range of days, or **Ctrl+Click** to select non-contiguous days.

Description	How to Set It
Aggregation by	Select the time unit by which to aggregate data. The default is Hour. This works in conjunction with the next field, Aggregation interval, which determines the number of units for one interval of data aggregation.
Aggregation interval	Select the interval units in which to aggregate data. The default is 1. For example, if you aggregate by the Hour and select 1 here, data is aggregated once every hour.
Report settings	
Include parameter card?	Select the **Yes** check box to include a table in the report that lists parameter settings for the report Knowledge Script. By default, the table is included.
Include Availability detail table?	Specify whether to display the Availability detail table as part of the report. By default, the table is included.
Include Availability chart?	Specify whether to display the Availability chart as part of the report. By default, the chart is included.
Threshold on Availability chart	Enter an integer for the availability, as a percent (%), to use as a threshold on the chart. Default is 0, or no threshold is displayed.
Include Response Time detail table?	Specify whether to display the Response Time detail table as part of the report. By default, the table is included.
Include Response Time chart?	Specify whether to display the Response Time chart as part of the report. By default, the chart is included.
Units for Response Time report	Select the response time unit, either the default, msec, or sec.
Threshold on Response Time chart (selected units)	Specify the time for the threshold in units specified in the previous parameters, or use the default of 0.0. Zero suppresses the threshold indicator in the chart.
Select chart style	Options in the Chart Settings dialog box set the appearance of the chart. The same parameters are used in both the availability and Response Time charts, if both are produced. Default is Ribbon.
Select output folder	In the Specify report folder/filename dialog box, enter an output filename and fill in the remote folder fields.
Add job ID to output folder name?	Specify whether to add a job ID to the output folder name.
Index-Report Title	In the Report Properties dialog box, configure report title settings.
Add time stamp to title?	Specify whether to add a timestamp to the report title.
Event notification	
Generate event on success?	Specify whether an event is raised when a report is generated. By default, events are raised.
Severity level for report success	Set the severity level for a successful report. Default is 35 (magenta event indicator).
Severity level for report with no data	Set the severity level for a report with no data. Default is 25 (blue event indicator).
Severity level for report failure	Set the severity level for a report with no data. Default is 5 (red event indicator).

79.10 SendAndReceiveInternetMail

Use this Knowledge Script to monitor the response time taken to send and receive an Internet mail message using the POP3 and SMTP protocols.

You can run this script as "Interactive User." This setting *requires* a user to be physically logged into the computer for the test to run. You might want to do this in environments where a firewall is preventing access to an Active Directory domain controller, or where the test computer is part of a workgroup and not part of a domain. With this feature, the user is not validated, so the test can proceed despite the lack of access to the domain. To run as interactive user, type "`Interactive User`" for the **Run As Username** parameter, and leave the **Password** and **Domain** parameters blank.

79.10.1 Collecting Data

If you choose to collect data, this Knowledge Script generates the following data streams:

- **Response time**
  - **Overall response time**. The information returned by this data stream is also saved with the data point, and can be viewed by double-clicking the data point in the Graph Pane or Chart Console.
  - **Response-time Breakdown**. If enabled as separate parameters, up to 5 response-time breakdown data streams. These data streams are individual data points for the different parts of the Knowledge Script transaction that are timed. For more information, see "Setting Parameter Values" on page 4607.
- **Availability:** Returns one of the following values:
  - 1 or 100 = the transaction was successful
  - 0 = the transaction was not successful

  The Availability data point is an indication of whether the test succeeded or failed. If, for example, a connection to the POP3 mail server was established but the message was never sent, the Availability data point is 0, which indicates not available or not successful.

An event is raised whenever one of the following occurs:

- A threshold that you have specified as an event parameter is exceeded.
- The Web-RT InternetMail engine cannot be initialized. An initialization error is generated, but an Availability or Response Time data stream is not generated.
- The transaction does not complete successfully. A transaction error is generated. Only an Availability data stream is generated, with a value of 0.

You can select where some of the possible events are displayed in the Operator Console TreeView or Control Center Console Server view. This event proxying feature is useful in Control Center Service Map views. It is not supported for jobs that are started in the Operator Web Console. See the description of the **Event on** parameter in the following table.

79.10.2 Resource Object

Internet Mail

79.10.3 Default Schedule

The default interval for this Knowledge Script is Every 15 minutes.

79.10.4 Setting Parameter Values

Set the following parameters as needed

Description	How to Set It
Availability	
Collect data for availability?	Select the **Yes** check box to collect availability data for graphs and reports. If enabled, the Knowledge Script returns: • 1 or 100 = the server responded to the connection request. • 0 = the server did not respond. By default, data is collected.
Data stream format	Select the data stream format for the Availability data stream. Previous versions of AppManager ResponseTime for Web used a 0 ("not available") or 1 ("available") format to indicate availability. You now have the option to use a 0 ("not available") or 100 ("available") format. The default value is 0-100.
Raise event if transaction fails?	Select the **Yes** check box to raise events. By default, events are raised.
Event severity when transaction fails	Set the event severity level, from 1 to 40, to indicate the importance of the event. Default is 5 (red event indicator).
Response Time	
Collect data for response time?	Select the **Yes** check box to collect data for graphs and reports. By default, data is collected.
Threshold – Maximum response time (seconds)	Specify the maximum response time in seconds. When response time exceeds this value, an event is raised. The event message contains a breakdown of the total response time. The default is 15 seconds.
Raise event when threshold is exceeded?	Select the **Yes** check box to raise an event when the threshold is exceeded. By default, events are raised.
Event severity when threshold exceeded	Set the event severity level, from 1 to 40, to indicate the importance of the event. Default is 15 (yellow event indicator). If you disable Response Time events, this value is ignored.
Response Time Breakdown	
Collect data for connecting to SMTP server?	Select the **Yes** check box to collect a separate response-time data stream for the time taken to connect to the SMTP server. By default, separate response-time data streams are not collected.
Collect data for sending message?	Select the **Yes** check box to collect a separate response-time data stream for the time taken to send the test message. By default, separate response-time data streams are not collected.
Collect data for connecting to POP3 server?	Select the **Yes** check box to collect a separate response-time data stream for the time taken to connect to the POP3 server. By default, separate response-time data streams are not collected.

Description	How to Set It
Collect data for scanning incoming mail for message?	Select the **Yes** check box to collect a separate response-time data stream for the time taken to check the mailbox for the test message. By default, separate response-time data streams are not collected.
Collect data for receiving message?	Select the **Yes** check box to collect a separate response-time data stream for the time taken to receive the test message. By default, separate response-time data streams are not collected.
SMTP Server Settings	
Server name	Specify the name of the SMTP server, or click **Browse [...]** to select from a list of available servers. The server you select must already be in the TreeView. If you are setting the **Event on** parameter, the **Server name** parameter lets you select the server where the event appears in your console.
Server port number	Specify the port number of the SMTP server. Default is 25.
Server requires authentication?	Select the **Yes** check box if the SMTP server needs authentication. The default is Yes. You can specify to use the same POP3 server settings if the sender and the receiver's credentials are the same. If they are different, you can specify the credentials specific to SMTP server in the Sender's Details section.
Sender's Details	
Use same settings as POP3 server	If the credentials of the sender and the receiver is the same, select the **Yes** check box to use the same credentials specified for POP3 server. The default is Yes. If this is not selected, then the other three parameters within this section are mandatory.
Username	Specify the SMTP username of the client where you are running this Knowledge Script.
Password	Specify the SMTP password for the associated SMTP user name.
Email address	Specify the email address of the client where you are running this Knowledge Script job.
POP3 Server Settings	
Server name	Specify the name of the POP3 server, or click **Browse [...]** to select from a list of available servers. The server you select must already be in the TreeView. If you are setting the **Event on** parameter, the **Server name** parameter lets you select the server where the event appears in your console.
Server port number	Specify the port number of the POP3 server. Default is 110.
Username	Specify the POP3 username of the client where you are running this Knowledge Script.
Password	Specify the POP3 password for the associated POP3 user name.
Email address	Specify the email address of the client where you are running this Knowledge Script job.
Message size	Specify the number of bytes to include as text in the message body. Default is 1000.
Leave message on server?	Select the **Yes** check box to leave the message on the POP3 server. Clear the box to delete the message from the server. By default, messages are left on server.

Description	How to Set It
Event on	Select the TreeView location where events should be displayed. Select either: • **Agent** – The client computer in the response-time tests. This is the default. • **Server** – The mail server being tested; see the **Server name** parameter for the POP3 or SMTP server. • **Both –** The event is shown in two locations in the TreeView. **Notes** This setting does not apply to events related to the Knowledge Script itself, such as Knowledge Script failure or initialization problems. Such events are always displayed on the computer where the job ran. You must select `Agent` when starting jobs in the Operator Web Console. If you select `Server`, no events are generated. If you select `Both`, an event is only shown on the agent.
Run As	
Username	Specify the user ID associated with a specific user who has the required permissions to run this application. Leave the **Password** and **Domain** parameters blank if you specify "`Interactive User`".
Password	Specify the password associated with this user that is required to log on to the network and run the application.
Domain	Specify the domain name of the domain you are logging onto.
Administrators group on managed client	Specify the name of the Administrators Group on the managed object. Typically, this name is "Administrators", except on some foreign-language operating systems. The default is "`Administrators`".
Timeouts	
Job timeout	Set the timeout value, from 1 to 900 seconds, to determine the maximum time allowed to process a job before it's aborted. When an Web-RT Knowledge Script job runs, a job timer is started. If the transaction takes longer than the Job timeout, the transaction is stopped and a "Job Timeout" event is raised. The default is 120 seconds.
Queue timeout	Set the timeout value, from 1 to 1200 seconds, to determine how long a job can wait for resources before it's aborted. Multiple simultaneous Web-RT Knowledge Script jobs must wait for a token to run. If no token is available for a job you're trying to run, the job is added to the queue and starts a queue timer. When the Queue Timeout for a job expires, the job does not run, a "Queue Timeout" event is raised, and the job is moved to the end of the queue. The default is 300 seconds.
Connection timeout	Set the connection timeout value to determine how long a job can wait for a connection to the POP3 and SMTP servers before the job is aborted. The default is 30 seconds.

79.11 SendInternetMail

Use this Knowledge Script to monitor the response time taken to send an Internet mail message using the SMTP protocol.

You can run this script as "Interactive User." This setting *requires* a user to be physically logged into the computer for the test to run. You might want to do this in environments where a firewall is preventing access to an Active Directory domain controller, or where the test computer is part of a workgroup and not part of a domain. With this feature, the user is not validated, so the test can proceed despite the lack of access to the domain. To run as interactive user, type "`Interactive User`" for the **Run As Username** parameter, and leave the **Password** and **Domain** parameters blank.

79.11.1 Collecting Data

If you choose to collect data, this Knowledge Script generates the following data streams:

- **Response time**
  - **Overall response time**. The information returned by this data stream is also saved with the data point, and can be viewed by double-clicking the data point in the Graph Pane or Chart Console.
  - **Response-time Breakdown**. If enabled as separate parameters, up to 2 response-time breakdown data streams. These data streams are individual data points for the different parts of the Knowledge Script transaction that are timed. For more information, see "Setting Parameter Values" on page 4611.
- **Availability:** Returns one of the following values:
  - 1 or 100 = the transaction was successful
  - 0 = the transaction was not successful

  The Availability data point is an indication of whether the test succeeded or failed. If, for example, a connection to the POP3 mail server was established but the message was never sent, the Availability data point is 0, which indicates not available or not successful.

An event is raised whenever one of the following occurs:

- A threshold that you have specified as an event parameter is exceeded.
- The Web-RT InternetMail engine cannot be initialized. An initialization error is generated, but an Availability or Response Time data stream is not generated.
- The transaction does not complete successfully. A transaction error is generated. Only an Availability data stream is generated, with a value of 0.

You can select where some of the possible events are displayed in the Operator Console TreeView or Control Center Console Server view. This event proxying feature is useful in Control Center Service Map views. It is not supported for jobs that are started in the Operator Web Console. See the description of the **Event on** parameter in the following table.

79.11.2 Resource Object

Internet Mail

79.11.3 Default Schedule

The default interval for this Knowledge Script is Every 15 minutes.

79.11.4 Setting Parameter Values

Set the following parameters as needed

Description	How to Set It
Availability	
Collect data for availability?	Select the **Yes** check box to collect availability data for graphs and reports. If enabled, the Knowledge Script returns: • 1 or 100 = the server responded to the connection request. • 0 = the server did not respond. By default, data is collected.
Data stream format	Select the data stream format for the Availability data stream. Previous versions of AppManager ResponseTime for Web used a 0 ("not available") or 1 ("available") format to indicate availability. You now have the option to use a 0 ("not available") or 100 ("available") format. The default value is 0-100.
Raise event if transaction fails?	Select the **Yes** check box to raise events. By default, events are raised.
Event severity when transaction fails	Set the event severity level, from 1 to 40, to indicate the importance of the event. Default is 5 (red event indicator).
Response Time	
Collect data for response time?	Select the **Yes** check box to collect data for graphs and reports. By default, data is collected.
Threshold – Maximum response time (seconds)	Specify the maximum response time in seconds. When response time exceeds this value, an event is raised. The event message contains a breakdown of the total response time. The default is 15 seconds.
Raise event when threshold is exceeded?	Select the **Yes** check box to raise an event when the threshold is exceeded. By default, events are raised.
Event severity when threshold is exceeded	Set the event severity level, from 1 to 40, to indicate the importance of the event. Default is 15 (yellow event indicator). If you disable Response Time events, this value is ignored.
Response Time Breakdown	
Collect data for connecting to SMTP server?	Select the **Yes** check box to collect a separate response-time data stream for the time taken to connect to the SMTP server. By default, separate response-time data streams are not collected.
Collect data for sending message?	Select the **Yes** check box to collect a separate response-time data stream for the time taken to send the test message. By default, separate response-time data streams are not collected.
SMTP Server Settings	

Description	How to Set It
Server name	Specify the name of the SMTP server, or click **Browse [...]** to select from a list of available servers. The server you select must already be in the TreeView. If you are setting the **Event on** parameter, the **Server name** parameter lets you select the server where the event appears in your console.
Server port number	Specify the port number of the SMTP server. Default is 25.
Server requires authentication?	Select the **Yes** check box if the SMTP server needs authentication. The default is Yes.
Sender's Details	
Username	Specify the SMTP username of the client where you are running this Knowledge Script.
Password	Specify the SMTP password for the associated SMTP user name.
Email address	Specify the email address of the client (SMTP) where you are running this Knowledge Script job.
Email address	Specify the email address of the client (POP3) where you are running this Knowledge Script.
Message size	Specify the number of bytes to include as text in the message body. Default is 1000.
Event on	Select the TreeView location where events should be displayed. Select either: • **Agent** – The client computer in the response-time tests. This is the default. • **Server** – The mail server being tested; see the **Server name** parameter. • **Both** – The event is shown in two locations in the TreeView. **Notes** This setting does not apply to events related to the Knowledge Script itself, such as Knowledge Script failure or initialization problems. Such events are always displayed on the computer where the job ran. You must select `Agent` when starting jobs in the Operator Web Console. If you select `Server`, no events are generated. If you select `Both`, an event is only shown on the agent.
Run As	
Username	Specify the user ID associated with a specific user who has the required permissions to run this application. Leave the **Password** and **Domain** parameters blank if you specify "`Interactive User`".
Password	Specify the password associated with this user that is required to log on to the network and run the application.
Domain	Specify the domain name of the domain you are logging onto.
Administrators group on managed client	Specify the name of the Administrators Group on the managed object. Typically, this name is "Administrators", except on some foreign-language operating systems. The default is "`Administrators`".
Timeouts	
Job timeout	Set the timeout value, from 1 to 900 seconds, to determine the maximum time allowed to process a job before it's aborted. When an Web-RT Knowledge Script job runs, a job timer is started. If the transaction takes longer than the Job timeout, the transaction is stopped and a "Job Timeout" event is raised. The default is 120 seconds.

Description	How to Set It
Queue timeout	Set the timeout value, from 1 to 1200 seconds, to determine how long a job can wait for resources before it's aborted. Multiple simultaneous Web-RT Knowledge Script jobs must wait for a token to run. If no token is available for a job you're trying to run, the job is added to the queue and starts a queue timer. When the Queue Timeout for a job expires, the job does not run, a "Queue Timeout" event is raised, and the job is moved to the end of the queue. The default is 300 seconds.
Connection timeout	Set the connection timeout value to determine how long a job can wait for a connection to the POP3 and SMTP servers before the job is aborted. The default is 30 seconds.

79.12 SMTPConnect

Use this Knowledge Script to monitor the availability of an SMTP server. When the specified SMTP server does not respond to a connection to the SMTP port (port 25), an event is raised.

You can select where some of the possible events are displayed in the Operator Console TreeView or Control Center Console Server view. This event proxying feature is useful in Control Center Service Map views. It is not supported for jobs that are started in the Operator Web Console. See the description of the **Event on** parameter in the following table.

If you choose to collect data, a data stream for Availability is generated, with one of the following values:

- 1 or 100 = the SMTP server responded to the connection request, or
- 0 = the SMTP server did not respond.

  The Availability data point is an indication of whether the test succeeded or failed. If a connection to the SMTP server cannot be established, the Availability data point is 0, which indicates not available or not successful.

79.12.1 Resource Object

SMTP

79.12.2 Default Schedule

The default interval for this Knowledge Script is Every 15 minutes.

79.12.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Availability	
Collect data for availability?	Select the **Yes** check box to collect availability data for graphs and reports. If enabled, the Knowledge Script returns: • 1 or 100 = the SMTP server responded to the connection request. • 0 = the SMTP server did not respond. By default, data is collected.
Data stream format	Select the data stream format for the Availability data stream. Previous versions of AppManager ResponseTime for Web used a 0 ("not available") or 1 ("available") format to indicate availability. You now have the option to use a 0 ("not available") or 100 ("available") format. The default value is 0-100.
Raise event if connection fails?	Select the **Yes** check box to raise events. By default, events are raised.

Description	How to Set It
Event severity when connection fails	Set the event severity level, from 1 to 40, to indicate the importance of the event. Default is 5 (red event indicator).
SMTP Server	Specify the name of the SMTP server that you want to test. For example, `gazelle.netiq.com`. You can also click **Browse [...]** to select from a list of available servers. The server you select must already be in the TreeView. If you are setting the **Event on** parameter, the **SMTP Server** parameter lets you select the server where the event appears in your console. You can also pass a port number following the SMTP servername. For example, you can enter `gazelle.netiq.com:2500`.
Event on	Select the TreeView location where events should be displayed. Select either: • **Agent** – The client computer in the response-time tests. This is the default. • **Server** – The mail server being tested; see the **SMTP Server** parameter. • **Both** – The event is shown in two locations in the TreeView. **Notes** This setting does not apply to events related to the Knowledge Script itself, such as Knowledge Script failure or initialization problems. Such events are always displayed on the computer where the job ran. You must select `Agent` when starting jobs in the Operator Web Console. If you select `Server`, no events are generated. If you select `Both`, an event is only shown on the agent.

79.13 TakeDesktopOwnership

Use this Knowledge Script to reassign control of the desktop on the managed client computer when another module is controlling it.

NOTE: You only need to run this Knowledge Script if you are also using AppManager ResponseTime for Windows and you want to run Web-RT_WebTransaction Knowledge Scripts and Win-RT Knowledge Scripts on the same managed client.

Both Win-RT and Web-RT_WebTransaction Knowledge Scripts must have control of the desktop in order to run or play back. However, only one software application can control the desktop at any point. When a WebTransaction Knowledge Script runs, it checks for the value of the "`Desktop`" registry key on the managed client. If that value assigns control of the desktop to another software application, the Knowledge Script fails and displays a Playback error.

Use this Knowledge Script to overwrite any existing value for the "`Desktop`" registry key, located under `HKEY_LOCAL_MACHINE\SOFTWARE\NetIQ\Response Time`, and force control of the desktop to be granted to AppManager ResponseTime for Web.

79.13.1 Resource Object

Web-RT

79.13.2 Default Schedule

The default interval for this Knowledge Script is Run once.

79.13.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
General Settings	
Job Failure Notification	
Event severity when take desktop ownership fails?	Specify a severity level for the event raised when an error prevents the Knowledge Script from setting the registry value indicating that AppManager ResponseTime for Web has ownership of the desktop. Default is 5 (red event indicator).
Raise event if take desktop ownership successful?	Check the box to raise an event when the Knowledge Script updates the registry value indicating that AppManager ResponseTime for Web has ownership of the desktop. By default, events are not raised.
Event severity when take desktop ownership successful?	Specify a severity level for the event raised when the Knowledge Script updates the registry value indicating that AppManager ResponseTime for Web has ownership of the desktop. Default is 35 (magenta event indicator).

79.14 URLCheck

Use this Knowledge Script to monitor the availability and performance of URLs, including validating and searching for text, links, and objects. This Knowledge Script is generated by the **URL Check Recorder** extension.

The URL Properties configured in URL Check Recorder are distinct settings and cannot be edited in the Knowledge Script itself. The Knowledge Script parameters, which for the most part are determined by URL Check Recorder settings when the Knowledge Script was created, let you further configure or change Knowledge Script execution and results collection. You can make an additional set of customizations by editing the Knowledge Script Options, which let you determine the titles of events and data streams. To change these options or the URL Properties, you can check out the Knowledge Script, reopen it in URL Check Recorder, edit it, save it, and check it back in.

Knowledge Scripts created using the URL Check Recorder are different from the provided CheckURL Knowledge Script. The CheckURL Knowledge Script monitors a single URL and can only be modified using the Control Center or Operator Console. For more information, see CheckURL.

NOTE: Context-sensitive Help is not available for URLCheck Knowledge Scripts. To access Help for URLCheck Knowledge Scripts, launch the Help for AppManager. In the Table of Contents pane of the Help window, click **Knowledge Script Reference**, then **Web-RT Knowledge Scripts**. Scroll through the table shown in the right pane and click **URLCheck** to view Help for these Knowledge Scripts.

79.14.1 Resource Object

URL Check

79.14.2 Default Schedule

The default interval for these Knowledge Scripts is **Every hour**.

79.14.3 Setting Parameter Values

Set the following parameters as needed. This table includes all available parameters. Depending on how you configure URLCheck options for a particular Knowledge Script, some parameters may not be available.

Description	How to Set It
General	
Allow auto-redirects?	Select the **Yes** check box to allow auto-redirects of URLs. By default, redirects are allowed.
Details to be included in events	Set to `Failure` to collect details only on failure events, or `All` to collect for all results. Default is Failure.
Logical Target	Specify the identifier to use to enable retrieval of data streams by AppManager Analysis Center v2.0 and higher. By default, either the Label or the Link text for the first URL.

Description	How to Set It
Overall Availability	
Collect data (%)?	Select the **Yes** check box to collect data on the availability of the URLs as a percentage (%). By default, data is collected.
Threshold – Minimum overall URL availability (%)	Specify a threshold for the percentage of URLs that are available. Default is 100%.
Raise event when overall URL availability falls below threshold?	Select the **Yes** check box to raise an event when the number of available URLs falls below the threshold. By default, events are raised.
Details to be saved with Overall URL Availability data point	Set to Failure, Success, All, or None. • Failure – Only includes details for failure events or matched event criteria. • Success – Only includes successful results. • All – Includes details for all results. • None – Includes no data details. Default is None.
Individual Availability	
Individual URL Availability data stream format	Select the data stream format for the individual URL Availability data stream. Previous versions of AppManager ResponseTime for Web used a 0 (“not available”) or 1 (“available”) format to indicate availability. You now have the option to use a 0 (“not available”) or **100** (“available”) format. The default value is 0-100.
Overall Processing Time	
Collect data?	Select the **Yes** check box to collect data on the overall processing time taken for this Knowledge Script to run. By default, data is not collected.
Threshold – Maximum overall processing time	Set the maximum time allowed to perform all operations, including generating data and events, before an event is raised. The default is 180 seconds.
Raise event if threshold exceeded?	Select the **Yes** check box to raise events if the overall time to process the job exceeds the threshold. By default, events are not raised.
Timeouts	Use these parameters to set timeouts.
URL connection timeout	Specify a connection timeout in seconds. Default is 10 seconds.
URL download timeout	Specify a download timeout in seconds. Default is 30 seconds.
Event Severity	
Event severity when URL fails	Set the event severity level, from 1 to 40, to indicate the importance of the event raised when a check of an individual URL fails. Default is 10 (red event indicator).
Event severity when overall URL availability falls below threshold	Set the event severity level from 1 to 40 to indicate the importance of the event raised when the **Threshold – Minimum overall URL availability (%)** is not met. Default is 15 (yellow event indicator).
Event severity when processing time threshold exceeded	Set the event severity level, from 1 to 40, to indicate the importance of the event when the overall processing time threshold is exceeded. The default severity level is 20 (blue event indicator).

Description	How to Set It
Event severity when URL is redirected	Set the event severity level, from 1 to 40, to indicate the importance of the event raised when a checked URL redirects to one or more subsequent URLs. The default severity level is 20 (yellow event indicator).
Event severity when connection time threshold is exceeded	Set the event severity level for the **Measure connection time** threshold from 1 to 40 to indicate the importance of the event raised when the URL download threshold is exceeded. Default severity level is 21 (blue event indicator).
Event severity when download time threshold is exceeded	Set the event severity level for the **Measure download time** threshold from 1 to 40 to indicate the importance of the event raised when the URL download threshold is exceeded. Default severity level is 21 (blue event indicator).
Event severity when link validation is in error	Set the event severity level when a link on a page has an HTTP status code or any WinHTTP errors, to indicate the importance of the event. Default is 22 (blue event indicator). For more information, see "Status Code and Status Description" on page 4619.
Event severity when object validation is in error	Set the event severity level when an object on a page has an HTTP status code or any WinHTTP errors, to indicate the importance of the event. Default is 22 (blue event indicator). For more information, see "Status Code and Status Description" on page 4619.
Event severity when search string criteria are met	Set the event severity level when a string is Found or Not Found, from 1 to 40, to indicate the importance of the event. Default is 25 (blue event indicator).
Event severity when search link criteria are met	Set the event severity level when a link is Found or Not Found, from 1 to 40, to indicate the importance of the event. Default is 25 (blue event indicator).
Event severity when search object criteria are met	Set the event severity level when an object is Found or Not Found, from 1 to 40, to indicate the importance of the event. Default is 25 (blue event indicator).
Collect data for Total of Connection Times?	Select the **Yes** check box to collect data on the time it took, in seconds, to connect to each Web page and download the first byte of information from each. By default, data is not collected.
Collect data for Total of Download Times?	Select the **Yes** check box to collect data on the time it took, in seconds, to fully download all Web pages, including the HTML and all associated components. By default, data is not collected.

79.14.4 Status Code and Status Description

For each URL that is verified, the status code and status description from the Web server are returned. This also applies to redirected URLs.

URLs that return `1xx`, `2xx` and `3xx` HTTP Status codes are considered successes, while `4xx` or `5xx` HTTP Status codes, WinHTTP error codes (`12xxxx`), or Windows Sockets error codes (`11xxxx`) are considered failures. For more information, see .

For more information about HTTP status codes and Windows Socket error codes, see the following references.

Category	Link
HTTP status codes	http://msdn2.microsoft.com/en-us/library/Aa384325.aspx
WinHTTP error codes	http://msdn2.microsoft.com/en-us/library/Aa383770.aspx
Windows Sockets error codes	http://msdn2.microsoft.com/en-us/library/ms740668.aspx

79.14.5 Redirects

By default, when checking the status of a URL that is redirected, both the original URL and all subsequently redirected URLs are verified, and status is returned for all URLs. This option can be disabled by disabling the **Allow Auto-Redirects?** parameter.

79.14.6 Timeouts

The URL connection timeout and URL download timeouts can be modified if connections and downloads are timing out. In most cases, you get an error code of 12002 for timeout conditions. For more information, see .

79.15 WebTransaction

The Web Recorder extension lets you record a typical set of user transactions on a Web site and save this information as an AppManager Knowledge Script. When you check in the new Knowledge Script, it is added to the Web-RT category by default.

You can then run the Knowledge Script on any computer that has the Web-RT module installed. The generated Knowledge Script allows you to monitor the availability and response time required to complete the entire transaction, as well as the individual steps within the transaction.

You can select where some of the possible events are displayed in the Operator Console TreeView or Control Center Console Server view. This event proxying feature is useful in Control Center Service Map views. It is not supported for jobs that are started in the Operator Web Console. See the description of the **Event on** parameter in the following table.

Each WebTransaction Knowledge Script contains all information you entered while performing and recording the transaction. Any information that is encrypted during the recorded browsing session is also encrypted in the resulting Knowledge Script.

NOTE: When you generate WebTransaction Knowledge Scripts with Web Recorder, you rename them in order to save the contents of each transaction. However, this means that the context-sensitive Help no longer works from the renamed Knowledge Scripts. To access Help for WebTransaction Knowledge Scripts, launch the Help for AppManager. In the left pane of the Help window, click **Knowledge Script Reference** in the Table of Contents, then click **Web-RT Knowledge Scripts** to see the table of Knowledge Script types.

79.15.1 Resource Object

Web Transaction

79.15.2 Default Schedule

The default interval for this Knowledge Script type is Every 15 minutes.

79.15.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
General	
Run in silent mode?	Select the **Yes** check box to instruct the Knowledge Script to play back without displaying anything on the computer screen. **NOTE:** Silent mode is not available if the Knowledge Script contains any steps that have the `MouseMove` option enabled. By default, silent mode is enabled.

Description	How to Set It
Execution speed	Set to `Slow`, `Medium`, or `Fast` to determine how fast the Knowledge Script plays back on the managed client. This parameter is controlled by means of the Playback Speed function in Web Recorder. By default, the execution speed is set to Medium. Refer to the Web Recorder online Help for the values.
Logical Target	Enter an identifier to use to enable retrieval of all data streams in AppManager Analysis Center v2.0 and higher. By default, this field is set with information from the first Navigate step. It may be, for example, the URL of the page accessed.
Target Computer	Enter an identifier to use to enable retrieval of all data streams in AppManager Analysis Center v2.0 and higher. Select the name of the target Web server for the transaction from the list of monitored Web servers. If you are setting the **Event on** parameter, the **Target Computer** parameter lets you select the server where the event appears in your console. This field may be left blank, which is the default setting.
Log Session Transcript?	Select the **Yes** check box to create a log file containing the session transcript of the Knowledge Script Playback. If enabled, saves the log file in the `..\NetIQ\AppManager\temp\ netiq_debug\[computername]` directory. The log filename is `Web-RT[JobNumber]Transcript.log`. By default, no log is created. **NOTE:** This option should only be enabled to aid in the debugging of problems.
Event on	Select the TreeView location where events should be displayed. Select either: • **Agent** – The client computer in the response-time tests. This is the default. • **Server** – The Web server being tested; see the **Target Computer** parameter. • **Both** – The event is shown in two locations in the TreeView. **Notes** This setting does not apply to events related to the Knowledge Script itself, such as Knowledge Script failure or initialization problems. Such events are always displayed on the computer where the job ran. You must select `Agent` when starting jobs in the Operator Web Console. If you select `Server`, no events are generated. If you select `Both`, an event is only shown on the agent.
Capture browser snapshot when object not found?	Select the **Yes** check box to instruct Web Recorder to take a screen capture of the browser window if the step fails because an object is not found. Enable this parameter to take a screen capture in JPEG (`.jpg`) format. The image file is saved to `..\NetIQ\temp\netiq_debug\[ComputerName]`. The filename begins with “WebTransaction” and the job ID number, and it includes the time and date. **Tip** To ensure that the screen capture shows the entire page, re-record the transaction. While recording, click **Maximize** in the browser window. When you return to the Web Recorder window, a Resize Browser step is available. Set the coordinates as needed to make the browser window as large as possible. See the following parameter for another snapshot option.

Description	How to Set It
Capture HTML snapshot when object not found?	Select the **Yes** check box to instruct Web Recorder to take a snapshot of the browser window if the step fails because an object is not found. Enable this parameter to take a screen capture in HTML (`.htm`) format. The HTML file is saved to `..\NetIQ\temp\netiq_debug\[ComputerName]`. The filename begins with "WebTransaction" and the job ID number, and it includes the time and date. See the previous parameter for another snapshot option.
Capture browser snapshot on Navigate Errors?	Select the **Yes** check box to instruct Web Recorder to take a screen capture of the browser window if the step fails because of a Navigate Error. Enable this parameter to take a screen capture in JPEG (`.jpg`) format. The image file is saved to `..\NetIQ\temp\netiq_debug\[ComputerName]`. The filename begins with "WebTransaction" and the job ID number, and it includes the time and date. **Tip** To ensure that the screen capture shows the entire page, re-record the transaction. While recording, click **Maximize** in the browser window. When you return to the Web Recorder window, a Resize Browser step is available. Set the coordinates as needed to make the browser window as large as possible. See the following parameter for another snapshot option.
Capture HTML snapshot on Navigate Errors?	Select the **Yes** check box to instruct Web Recorder to take a snapshot of the browser window if the step fails because of a Navigate Error. Enable this parameter to take a screen capture in HTML (`.htm`) format. The HTML file is saved to `..\NetIQ\temp\netiq_debug\[ComputerName]`. The filename begins with "WebTransaction" and the job ID number, and it includes the time and date. See the previous parameter for another snapshot option.
Capture extra snapshot?	Select the **Yes** check box if previous snapshots were taken too early and provided irrelevant information. Enabling this option might allow the Web Recorder to take additional snapshots of the browser window. Enabling this option increases the chance that you may capture a snapshot with better information about the problem. Web Recorder might take many extra snapshots, or none at all depending on the behavior of the Web page itself.
Overall Availability	
Collect data?	Select the **Yes** check box to collect data on the overall availability of the Web sites tested by this Knowledge Script. By default, data is collected.
Overall Response Time	
Collect data?	Select the **Yes** check box to collect data on the overall availability of the Web sites tested by this Knowledge Script. By default, data is collected. **NOTE:** You can specify *not* to include data collected on individual steps in overall response time.
Threshold – Maximum overall response time	Set the maximum response time that can be calculated for all steps in the transaction as a whole before an event is raised. The default is 120 seconds.
Raise event if threshold exceeded?	Select the **Yes** check box to raise events if the overall response time threshold is exceeded. By default, events are not raised.
Event severity when threshold exceeded	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default severity level is 15 (yellow event indicator).
Overall Processing Time	

Description	How to Set It
Collect data?	Select the **Yes** check box to collect data on the overall processing time taken for this Knowledge Script to run. By default, data is not collected.
Threshold – Maximum overall processing time	Set the maximum time that can be taken to run the entire recorded transaction before an event is raised. The default is 180 seconds.
Raise event if threshold exceeded?	Select the **Yes** check box to raise events if the overall processing time threshold is exceeded. By default, events are not raised.
Event severity when threshold exceeded	Set the event severity level, from 1 to 40, to indicate the importance of the event when the overall processing time threshold is exceeded. The default severity level is 20 (yellow event indicator).
Timers	Use these parameters to determine timeouts and set boundaries for discrete transaction steps. **NOTE:** Time added to a Knowledge Script from one of these timers is not included in response-time measurements, which is returned as the Total Response Time. It is only included in the Total Processing Time shown in the results.
Queue timeout	Set the timeout value, from 1 to 60 minutes, to determine how long a job can wait for resources before it is aborted. Multiple simultaneous WebTransaction Knowledge Script jobs must wait for a token to run because they all depend on Internet Explorer. If no token is available for a job you are trying to run, the transaction is added to the queue and starts a queue timer. When the queue timeout for a job expires, the transaction does not run, a "Queue Timeout" event is raised, and the transaction is moved to the end of the queue. The default is 5 minutes.
Job timeout	Set the timeout value, from 1 60 minutes, to determine the maximum time allowed to process a job before it is aborted. When a WebTransaction Knowledge Script job runs, a job timer is started. If the transaction takes longer than the job timeout, the transaction is stopped and a "Job Timeout" event is raised. This avoids allowing any job to use Internet Explorer resources for too long. The default is 5 minutes. **NOTE:** The Total Processing Time shown in the results after Playback is a guideline for determining an appropriate job timeout value: the job timeout value should be slightly greater than the maximum Total Processing Time.
Consider document complete *N* seconds after page change	Set the value, from 1 to 30 seconds, to determine how long Web Recorder should wait after a Web page transition event to consider the page download complete. This timer lets Web Recorder complete a transaction step even if it never receives the `Document Complete` signal from Internet Explorer to indicate that the page has been fully loaded. The default is 20 seconds.

Description	How to Set It
Consider document complete *N* seconds after Download Complete	Set the value, from 5 to 300 seconds, to determine how long Web Recorder should wait after receiving a `Download Complete` signal from Internet Explorer to consider the page to be completely loaded. This timer lets Web Recorder complete a transaction step even if it never receives the proper signal from Internet Explorer to indicate that the new page has been fully loaded. The default is 10 seconds.
Delay after document complete	Set the value, from 0 to 10 seconds, to determine whether and how long Web Recorder should pause before moving on to a new step. Internet Explorer can sometimes send several "final" `Document Complete` signals. Web Recorder may therefore consider the step to be complete at the first `Document Complete` signal, before all objects are actually rendered. This option means that Web Recorder waits for up to 10 seconds after it has determined that the step is complete before it moves on to the next step, giving all objects a further opportunity to be retrieved. The default is 1 second.
Global Step Options	
Event severity when threshold exceeded	Set the event severity level, from 1 to 40, to indicate the importance of the event when the response time for any individual step exceeds its threshold. The default severity level is 16 (yellow event indicator).
Event severity when step fails	Set the event severity level, from 1 to 40, to indicate the importance of the event when any individual step fails. The default severity level is 10 (red event indicator).
Event severity on Navigate Error	Set the event severity level, from 1 to 40, to indicate the importance of the event when any individual step fails because of a Navigate Error. The default severity level is 18 (yellow event indicator).
Step [n] [x] [d]	Use the parameters in the individual step folders to set options for data collection, to define threshold values, and to enable events. Each step is identified by its step index number (variable `n`), its step type (variable `x)`, and a step description (variable `d`). For more information, see .
Collect data for availability?	Select the **Yes** check box to collect data on the availability of the Web page accessed by this step. By default, data is not collected, but this value depends on what you have set in the **Knowledge Script** tab of the Web Recorder Options.
Collect data for response time?	Select the **Yes** check box to collect data on the response time taken to load the Web page accessed by this step. By default, data is not collected, but this value depends on what you have set in the **Knowledge Script** tab of the Web Recorder Options.
Included in Overall Response Time?	Select the Yes check box to include collected data in the Overall Response Time. By default, data is included. **NOTE:** Ensure you include the collected data from at least one step, or your overall response time is zero.
Threshold – Maximum response time	Set the maximum time that can be taken to complete this transaction step before an event is raised. The default is 30 seconds. This value depends on what you have set in the **Knowledge Script** tab of the Web Recorder Options.

Description	How to Set It
Raise event if threshold is exceeded?	Select the **Yes** check box to raise events if the response time threshold is exceeded. By default, events are enabled. The event severity that you set in the Global Step Options folder applies to this event.

80 WebSphereAppSrvUNIX Knowledge Scripts

AppManager provides Knowledge Scripts for monitoring WebSphere Application Servers.

From the Knowledge Script view of the Control Center console, you can access more information about any NetIQ-supported Knowledge Script by selecting it and pressing F1.

Administrative Knowledge Scripts

The following Knowledge Scripts perform administrative tasks associated with WebSphere Application Server:

Knowledge Script	What It Does
NetIQAgent	Starts or stops the Java server that the managed object uses to communicate with WebSphere Application Server.
SetRMFilters	Sets filters for logging request metrics traces.
SetServerLogPath	Sets the path of the server's primary JVM log file.
StartServer	Starts an application server instance.
StopServer	Stops an application server instance.

Dynamic Cache Knowledge Scripts

The following Knowledge Scripts are focused on the dynamic cache:

Knowledge Script	What It Does
DynamicCacheEviction	Returns the number of local and remote requests made.
DynamicCacheHits	Returns the number of cache hits in memory and on disk, and the number of cache misses.

Enterprise Java Bean Knowledge Scripts

The following Knowledge Scripts are focused on Enterprise Java Beans (EJBs):

Knowledge Script	What It Does
EJBActivation	Returns counts and response times for activation and passivation of entity and stateful session beans.
EJBMessageDelivery	Returns the number of messages that were delivered, and that failed to be delivered, to message driven beans.
EJBMessageSession	Returns server session statistics for the message driven bean pool.
EJBMethodCalls	Returns counts and response times for bean method calls.
EJBPersistence	Returns counts and response times for entity bean loads and stores.
EJBPool	Returns statistics on pool usage for entity and stateless beans.

NOTE:

- Activation and passivation counts are supported; activation and passivation times are not.
- Load and store counts are supported; load and store times are not.

Health Knowledge Scripts

The following Knowledge Scripts monitor general availability or performance metrics of WebSphere Application Server:

Knowledge Script	What It Does
Availability	Monitors the availability of the application server instance.
HealthCheck	Verifies that the server is running and can respond to requests.
RequestMetrics	Monitors the amount of time a node spent processing a request.
ServerCPU	Returns CPU utilization of the application server.
ServerScanLog	Scans the server's JVM log file(s) for lines matching a pattern. See also the SetServerLogPath Knowledge Script.

J2C Connection Pool Knowledge Scripts

The following Knowledge Scripts are focused on Java 2 Connectivity (J2C) connection pools:

Knowledge Script	What It Does
J2CUsage	Returns connection usage statistics.
J2CWaits	Returns statistics regarding how many clients are waiting for connections, and how long those clients have to wait.

JDBC Connection Pool Knowledge Scripts

The following Knowledge Scripts are focused on Java Database Connectivity (JDBC) connection pools:

Knowledge Script	What It Does
JDBCDriver	Returns the amount of time, in seconds, that the JDBC data source spent running in the JDBC driver, which includes time spent in the JDBC driver, network, and database.
JDBCUsage	Returns connection usage statistics.
JDBCWaits	Returns the amount of time, in seconds, that a JDBC data source spent waiting for a JDBC connection.

JVM Runtime Knowledge Scripts

The following Knowledge Scripts are focused on the Java Virtual Machine (JVM) runtime:

Knowledge Script	What It Does
JVMGCStats	Returns garbage collection statistics, including the count and duration of garbage collections.
JVMHeap	Returns memory help usage statistics.
JVMLocks	Returns the number of waits for a lock that have occurred, and the average wait time.
JVMObjects	Returns object creation and deletion statistics.
JVMThreads	Returns thread creation and destruction statistics.

These Knowledge Scripts require the JVM interface to be running

Object Request Broker Knowledge Scripts

The following Knowledge Scripts are focused on the Object Request Broker (ORB):

Knowledge Script	What It Does
ORBInterceptor	Returns the processing time for each ORB interceptor.
ORBRequests	Returns ORB request statistics, including the average object reference lookup time, the number of requests received, and the average number of concurrent requests.

Reporting Knowledge Script

The following report is focused on WebSphere Application Server:

Knowledge Script	What It Does
Report_HealthSummary	Reports the availability and response time characteristics of one or more WebSphere Application Servers.

Session Manager Knowledge Scripts

The following Knowledge Scripts are focused on the Session Manager:

Knowledge Script	What It Does
SessionErrors	Returns information about session errors that have occurred.
SessionInvalid	Returns statistics related to session invalidations.
SessionLifetime	Returns statistics related to session lifetime.

Thread Pool Knowledge Script

The following Knowledge Script is focused on thread pools:

Knowledge Script	What It Does
ThreadPoolUsage	Returns various thread pool statistics, including the number of threads created and destroyed, the number of active threads, the thread pool size, and the percentage of time that all threads in the pool are in use.

Transaction Manager Knowledge Scripts

The following Knowledge Scripts are focused on the Transaction Manager:

Knowledge Script	What It Does
TransactionCommits	Returns statistics about the number of local and global transactions committed, rolled back, and timed out.
TransactionDuration	Returns statistics about the duration of local and global transaction prepares and commits.

Web Application and Servlet Knowledge Scripts

The following Knowledge Scripts are focused on Web applications and servlets:

Knowledge Script	What It Does
ServletErrors	Returns the number of errors that have occurred while servicing requests.
ServletRequests	Returns statistics on the number of requests made, and the response time for servicing those requests.
WebAppLoads	Returns the number of servlets that were loaded and reloaded.

Web Services Gateway Knowledge Script

The following Knowledge Script is focused on the Web services gateway:

Knowledge Script	What It Does
WSGWRequests	Returns the number of synchronous and asynchronous requests received and responses sent.

Workload Manager Knowledge Scripts

The following Knowledge Scripts are focused on the Workload Manager:

Knowledge Script	What It Does
WLMClientRequests	Returns the number of outgoing requests, and the average response time to service those requests.
WLMServerRequests	Returns the number of incoming requests of various types, and the average number of concurrent requests.

80.1 Availability

Use this Knowledge Script to monitor the availability of WebSphere Application Server. This script monitors the availability of the application server instance.

80.1.1 Resource Object

WebSphere Application Server

80.1.2 Default Schedule

The default interval for this script is Every 15 Minutes.

80.1.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event? (y/n)	Set to **y** to raise an event if the server is down. The default is y.
Collect data? (y/n)	Set to **y** to collect data for reports and graphs. The default is n.
Event severity when application server is not running	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 10.

80.2 DynamicCacheEviction

Use this Knowledge Script to monitor cache entry evictions (invalidations). The script records the following data:

- The number of cache entries evicted from memory by a Least Recently Used (LRU) algorithm. These entries are written to disk if disk overflow is enabled.
- The number of cache entries evicted from memory and/or disk because their timeout expired.
- The number of cache entries explicitly invalidated from memory.
- The number of cache entries explicitly invalidated from disk.

You can set this script to raise an event if the number of cache entries evicted from memory exceeds a specified threshold. Excessive eviction of memory cache entries can point to a need to increase the memory cache size.

80.2.1 Resource Object

Dynamic Cache

80.2.2 Default Schedule

The default interval for this script is Every 15 minutes.

80.2.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event? (y/n)	Set to **y** to raise an event if a threshold is exceeded. The default is y.
Collect data? (y/n)	Set to **y** to collect data for reports and graphs. The default is n.
Include results for individual templates? (y/n)	Set to **n** to disable collection of data and event triggering for individual cache templates, so that only aggregate data for all cached templates is processed. The default is y. **NOTE:** If you run this Knowledge Script on an individual template (rather than on the Dynamic Cache node) and this parameter is set to n, the script will not perform any actions.
LRU evictions threshold	Specify a threshold value using an integer greater than or equal to -1. Use -1 to ignore this threshold. If the number of LRU evictions exceeds this threshold, an event is raised. The default is -1.
Event severity when LRU evictions exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of LRU evictions exceeds the threshold. The default is 25.

Description	How to Set It
Timeout evictions threshold	Specify a threshold value using an integer greater than or equal to -1. Use -1 to ignore this threshold. If the number of timeout evictions exceeds this threshold, an event is raised. The default is -1.
Event severity when timeout evictions exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of timeout evictions exceeds the threshold. The default is 25.

80.3 DynamicCacheHits

Use this Knowledge Script to monitor the dynamic cache hit/miss statistics. The dynamic cache is used to cache servlet and JSP results, Web services, and WebSphere Application Server commands and patterns. This script records the number of hits in memory, the number of hits on disk, and the number of misses (object not found in memory or disk cache). You can set a threshold on the cache hit ratio, which is the number of cache hits (disk plus memory) divided by the total number of hits and misses, expressed as a percentage.

80.3.1 Resource Object

Dynamic Cache

80.3.2 Default Schedule

The default interval for this script is Every 15 Minutes.

80.3.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event? (y/n)	Set to **y** to raise an event if the average hit ratio (expressed as a percentage) falls below the threshold. The default is y.
Collect data? (y/n)	Set to **y** to collect data for reports and graphs. The default is n.
Include results for individual templates? (y/n)	Set to **n** to disable collection of data and event triggering for individual cache templates, so that only aggregate data for all cached templates is processed. The default is y. **NOTE:** If you run this Knowledge Script on an individual template (rather than on the Dynamic Cache node) and this parameter is set to n, the script will not perform any actions.
Cache hit ratio threshold	Specify a threshold value using an integer greater than or equal to -1. Use -1 to ignore this threshold. If the average hit ratio (expressed as a percentage) falls below this threshold, an event is raised. The default is -1.
Event severity when cache hit ratio falls below threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.

80.4 EJBActivation

Use this Knowledge Script to monitor Enterprise Java Bean (EJB) activation rates. The script reports on the number of EJB activations and passivations, and the average amount of time required to activate and passivate an EJB. This script applies only to entity and stateful session EJBs.

This Knowledge Script requires time to complete an iteration before starting a new one. Do not set the interval to be less than Every 5 minutes.

NOTE: To discover EJB objects, an application running EJB must be available when you run the Discovery_WebSphereAppSrvUNIX Knowledge Script.

80.4.1 Resource Object

Enterprise Java Beans node or a stateful EJB module

80.4.2 Default Schedule

The default interval for this script is Every 15 minutes.

80.4.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event? (y/n)	Set to **y** to raise an event if a threshold is exceeded. The default is y.
Collect data? (y/n)	Set to **y** to collect data for reports and graphs. The default is n.
Include results for individual EJB modules? (y/n)	Set to **n** to aggregate event and data details for the EJB modules that belong to an Enterprise Java Beans node. The default is y. If you run this script on a particular EJB module, rather than on the Enterprise Java Beans node, and this parameter is set to **n**, the script will not perform any actions unless the **Include results for individual EJBs** parameter is set to y.
Include results for individual EJBs? (y/n)	Set to **n** to disable collection of data and event triggering for individual EJBs, so that only aggregate data for the EJB module or Enterprise Java Bean collection is included. The default is y. **NOTE:** If you run this Knowledge Script on an individual EJB (rather than on the Enterprise Java Beans node, or on an EJB module) and this parameter is set to n, the script will not perform any actions.
Activations threshold	Specify a threshold value using an integer greater than or equal to -1. Use -1 to ignore this threshold. If the number of EJB activations exceeds this threshold, an event is raised. The default is -1.

Description	How to Set It
Event severity when activations exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of EJB activations exceeds the threshold. The default is 25.
Passivations threshold	Specify a threshold value using an integer greater than or equal to -1. Use -1 to ignore this threshold. If the number of EJB passivations exceeds this threshold, an event is raised. The default is -1.
Event severity when passivations exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of EJB passivations exceeds the threshold. The default is 25.
Average activation time threshold	Specify a threshold value greater than or equal to -1. Use -1 to ignore this threshold. If the average activation time (in seconds) exceeds this threshold, an event is raised. The default is -1.
Event severity when average activation time exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the average activation time (in seconds) exceeds this threshold. The default is 25.
Average passivation time threshold	Specify a threshold value greater than or equal to -1. Use -1 to ignore this threshold. If the average passivation time (in seconds) exceeds this threshold, an event is raised. The default is -1.
Event severity when average passivation time exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the the average passivation time (in seconds) exceeds the threshold. The default is 25.

80.5 EJBMessageDelivery

Use this Knowledge Script to monitor Enterprise Java Bean (EJB) message delivery statistics, for message-driven beans only. The script records the number of message delivery attempts, such as calls to a EJB's `onMessage` method, and the number of successful attempts.

This Knowledge Script requires time to complete an iteration before starting a new one. Do not set the interval to be less than Every 5 minutes.

NOTE: To discover EJB objects, an application running EJB must be available when you run the Discovery_WebSphereAppSrvUNIX Knowledge Script.

80.5.1 Resource Object

Enterprise Java Beans node or a message-driven EJB module

80.5.2 Default Schedule

The default interval for this script is Every 15 minutes.

80.5.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event? (y/n)	Set to **y** to raise an event if the percent of messages that failed to be delivered exceeds the threshold. The default is y.
Collect data? (y/n)	Set to **y** to collect data for reports and graphs. The default is n.
Include results for individual EJB modules? (y/n)	Set to **n** to aggregate event and data details for the EJB modules that belong to an Enterprise Java Beans node. The default is y. If you run this script on a particular EJB module, rather than on the Enterprise Java Beans node, and this parameter is set to **n**, the script will not perform any actions unless the **Include results for individual EJBs** parameter is set to y.
Include results for individual EJBs? (y/n)	Set to **n** to disable collection of data and event triggering for individual EJBs, so that only aggregate data for the EJB module or Enterprise Java Bean collection is included. The default is y. **NOTE:** If you run this Knowledge Script on an individual EJB (rather than on the Enterprise Java Beans node, or on an EJB module) and this parameter is set to n, the script will not perform any actions.
Failed message delivery percent threshold	Specify a threshold value using an integer greater than or equal to -1. Use -1 to ignore this threshold. If the percent of messages that failed to be delivered exceeds this threshold, an event is raised. The default is -1.
Event severity when failed message delivery percent exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.

80.6 EJBMessageSession

Use this Knowledge Script to monitor the server session pool used by message-driven Enterprise Java Beans (EJBs). The script records the average time to retrieve a ServerSession from the pool, and the percentage of the server session pool that is in use.

NOTE: To discover EJB objects, an application running EJB must be available when you run the Discovery_WebSphereAppSrvUNIX Knowledge Script.

80.6.1 Resource Object

Enterprise Java Beans node or a message-driven EJB module

80.6.2 Default Schedule

The default interval for this script is Every 15 minutes.

80.6.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event? (y/n)	Set to **y** to raise an event if a threshold is exceeded. The default is y.
Collect data? (y/n)	Set to **y** to collect data for reports and graphs. The default is n.
Include results for individual EJB modules? (y/n)	Set to **n** to aggregate event and data details for the EJB modules that belong to an Enterprise Java Beans node. The default is y. If you run this script on a particular EJB module, rather than on the Enterprise Java Beans node, and this parameter is set to **n**, the script will not perform any actions unless the **Include results for individual EJBs** parameter is set to y.
Include results for individual EJBs? (y/n)	Set to **n** to disable collection of data and event triggering for individual EJBs, so that only aggregate data for the EJB module or Enterprise Java Bean collection is included. The default is y. **NOTE:** If you run this Knowledge Script on an individual EJB (rather than on the Enterprise Java Beans node, or on an EJB module) and this parameter is set to n, the script will not perform any actions.
Average wait time threshold	Specify a threshold value greater than or equal to -1. Use -1 to ignore this threshold. If the average wait time (in seconds) to obtain a server session exceeds this threshold, an event is raised. The default is -1.
Event severity when average wait time exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the average wait time (in seconds) to obtain a server session exceeds the threshold. The default is 25.

Description	How to Set It
Server session pool usage threshold	Specify a threshold value using an integer greater than or equal to -1. Use -1 to ignore this threshold. If the average percentage of the server session pool in use exceeds this threshold, an event is raised. The default is -1.
Event severity when server session pool usage exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the average percentage of the server session pool in use exceeds the threshold. The default is 25.

80.7 EJBMethodCalls

Use this Knowledge Script to monitor Enterprise Java Bean (EJB) method call rates. The script reports on the number of EJB method calls, the current number of active methods, and the average amount of time required for each method call. This script applies to all EJBs.

NOTE: To discover EJB objects, an application running EJB must be available when you run the Discovery_WebSphereAppSrvUNIX Knowledge Script.

80.7.1 Resource Object

Enterprise Java Beans node or a single entity EJB module

80.7.2 Default Schedule

The default interval for this script is Every 15 minutes.

80.7.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event? (y/n)	Set to **y** to raise an event if the average time (in seconds) to complete a method call exceeds the threshold. The default is y.
Collect data? (y/n)	Set to **y** to collect data for reports and graphs. The default is n.
Include results for individual EJB modules? (y/n)	Set to **n** to aggregate event and data details for the EJB modules that belong to an Enterprise Java Beans node. The default is y. If you run this script on a particular EJB module, rather than on the Enterprise Java Beans node, and this parameter is set to **n**, the script will not perform any actions unless the **Include results for individual EJBs** parameter is set to y.
Include results for individual EJBs? (y/n)	Set to n to disable collection of data and event triggering for individual EJBs, so that only aggregate data for the EJB module or Enterprise Java Bean collection is included. The default is y. **NOTE:** If you run this Knowledge Script on an individual EJB (rather than on the Enterprise Java Beans node, or on an EJB module) and this parameter is set to n, the script will not perform any actions.
Average method call time threshold	Specify a threshold value greater than or equal to -1. Use -1 to ignore this threshold. If the average time (in seconds) to complete a method call exceeds this threshold, an event is raised. The default is -1.
Event severity when average method call time exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.

80.8 EJBPersistence

Use this Knowledge Script to monitor Enterprise Java Bean (EJB) persistence (load and store) rates. The script reports on the number of EJB loads and stores, and the average amount of time required to load and store an EJB. This script applies only to entity EJBs.

NOTE: To discover EJB objects, an application running EJB must be available when you run the Discovery_WebSphereAppSrvUNIX Knowledge Script.

80.8.1 Resource Object

Enterprise Java Beans node or a single entity EJB module

80.8.2 Default Schedule

The default interval for this script is Every 15 minutes.

80.8.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event? (y/n)	Set to **y** to raise an event if a threshold is exceeded. The default is y.
Collect data? (y/n)	Set to **y** to collect data for reports and graphs. The default is n.
Include results for individual EJB modules? (y/n)	Set to **n** to aggregate event and data details for the EJB modules that belong to an Enterprise Java Beans node. The default is y. If you run this script on a particular EJB module, rather than on the Enterprise Java Beans node, and this parameter is set to **n**, the script will not perform any actions unless the **Include results for individual EJBs** parameter is set to y.
Include results for individual EJBs? (y/n)	Set to **n** to disable collection of data and event triggering for individual EJBs, so that only aggregate data for the EJB module or Enterprise Java Bean collection is included. The default is y. **NOTE:** If you run this Knowledge Script on an individual EJB (rather than on the Enterprise Java Beans node, or on an EJB module) and this parameter is set to n, the script will not perform any actions.
Loads threshold	Specify a threshold value using an integer greater than or equal to -1. Use -1 to ignore this threshold. If the number of EJB loads exceeds this threshold, an event is raised. The default is -1.
Event severity when loads exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of EJB loads exceeds the threshold. The default is 25.

Description	How to Set It
Stores threshold	Specify a threshold value using an integer greater than or equal to -1. Use -1 to ignore this threshold. If the number of EJB stores exceeds this threshold, an event is raised. The default is -1.
Event severity when stores exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of EJB stores exceeds the threshold. The default is 25.
Average load time threshold	Specify a threshold value greater than or equal to -1. Use -1 to ignore this threshold. If the average load time (in seconds) exceeds this threshold, an event is raised. The default is -1.
Event severity when average load time exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the average load time (in seconds) exceeds this threshold. The default is 25.
Average store time threshold	Specify a threshold value greater than or equal to -1. Use -1 to ignore this threshold. If the average store time (in seconds) exceeds this threshold, an event is raised. The default is -1.
Event severity when average store time exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the average store time (in seconds) exceeds the threshold. The default is 25.

80.9 EJBPool

Use this Knowledge Script to monitor Enterprise Java Bean (EJB) pool usage statistics for entity and stateless session beans. This script monitors:

- The number of calls retrieving an object from the pool.
- The number of times a retrieve found an object available in the pool.
- The number of calls returning an object to the pool.
- The number of times the returned object was discarded because the pool was full.

NOTE: To discover EJB objects, an application running EJB must be available when you run the Discovery_WebSphereAppSrvUNIX Knowledge Script.

80.9.1 Resource Object

Enterprise Java Beans node, or a single entity or stateless session EJB module

80.9.2 Default Schedule

The default interval for this script is Every 15 minutes.

80.9.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event? (y/n)	Set to **y** to raise an event if a threshold is exceeded. The default is y.
Collect data? (y/n)	Set to **y** to collect data for reports and graphs. The default is n.
Include results for individual EJB modules? (y/n)	Set to **n** to aggregate event and data details for the EJB modules that belong to an Enterprise Java Beans node. The default is y. If you run this script on a particular EJB module, rather than on the Enterprise Java Beans node, and this parameter is set to **n**, the script will not perform any actions unless the **Include results for individual EJBs** parameter is set to y.
Include results for individual EJBs? (y/n)	Set to **n** to disable collection of data and event triggering for individual EJBs, so that only aggregate data for the EJB module or Enterprise Java Bean collection is included. The default is y. **NOTE:** If you run this Knowledge Script on an individual EJB (rather than on the Enterprise Java Beans node, or on an EJB module) and this parameter is set to n, the script will not perform any actions.
Successful retrieval percent threshold	Specify a threshold value using an integer greater than or equal to -1. Use -1 to ignore this threshold. If the percent of retrievals that found an object available in the pool falls below this threshold, an event is raised. The default is -1.

Description	How to Set It
Event severity when successful retrieval percent falls below threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the percent of retrievals that found an object available in the pool falls below the threshold. The default is 25.
Successful return percent threshold	Specify a threshold value using an integer greater than or equal to -1. Use -1 to ignore this threshold. If the percent of returned objects that were not discarded because the pool was full falls below this threshold, an event is raised. The default is -1.
Event severity when successful return percent falls below threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the percent of returned objects that were not discarded because the pool was full falls below this threshold. The default is 25.

80.10 HealthCheck

Use this Knowledge Script to verify that WebSphere Application Server is running, and that a user-specified servlet running on the server is able to respond to requests. You can specify that an event be raised if the servlet response time exceeds a specified threshold. You can also specify that the server should be restarted if it is not running.

In order to test for the application server's ability to respond to requests, and to measure the server's responsiveness, you must supply the URL of a servlet to query. In addition, you can optionally specify a string expected to be found in the document returned from the query. The URL must be an HTTP URL, and must be a GET, and not a POST, request. It is not required that the URL point to the local computer on which the health check is being performed, nor is it required that the URL point to a servlet. However, querying a remote URL will effectively check the health of the remote server, rather than the server on which the Knowledge Script runs. This may be useful in cases where you want to measure the response time of a servlet running on one server from the point of view of one or more other servers.

If security is enabled on the WebSphere Application Server, you must use AppManager Security Manager to update the AppManager repository to provide the WebSphere Application Server account information that is required to start the application server.

If you are running the agent with a non-root account on WebSphere Application Server 8.0 or 8.5, ensure you have applied all required WebSphere Application Server fixes to start the server. Refer to the IBM support site regarding this problem http://www.ibm.com/support/docview.wss?uid=swg1PM63269/.

80.10.1 Resource Object

WebSphere Application Server

80.10.2 Default Schedule

The default interval for this script is Every 15 Minutes.

80.10.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event? (y/n)	Set to **y** to raise an event if a threshold is exceeded. The default is y.
Collect data? (y/n)	Set to **y** to collect data for reports and graphs. The default is n.
Event severity when the application server is not running	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the application server is not running. The default is 10.
Restart application server if not running? (y/n)	Set to **y** to restart the application server if it is not running. The default is n.
Start time limit	Set to the number of seconds within which WebSphere Application Server should complete initialization. The default is 300.

Description	How to Set It
URL of servlet to test server responsiveness	Specify an HTTP GET URL to be accessed in order to test whether the server is able to respond to requests in a timely manner. Leave blank if you do not want to test server responsiveness.
Event severity when the servlet is not responding to requests	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the servlet is not responding to requests. The default is 10.
Text expected to be found in servlet response	Specify a string that should be found in the response text returned by the servlet. You can specify that an event be raised if this text is not found in the response. Leave this field empty if you do not want to validate the servlet response.
Event severity when text not found in servlet response	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the servlet response does not include the text you specify. The default is 25.
Servlet response time threshold	Specify a threshold value greater than or equal to -1. Use -1 to ignore this threshold. If the response time (in seconds) exceeds this threshold, an event is raised. The default is -1.
Event severity when servlet response time exceeds the threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the response time (in seconds) exceeds this threshold. The default is 25.

80.11 J2CUsage

Use this Knowledge Script to monitor the J2C (Java 2 Connectivity) connection pool usage statistics. The script records the following data:

- The average percentage of the pool that is in use.
- The average percentage of the time that all connections in the pool are in use.
- The average time, in seconds, that a connection is in use.
- The number of ManagedConnection objects that are in use.
- The number of connection handles that are in use.

80.11.1 Resource Object

J2C Connection Pool, or a J2C Data Source

80.11.2 Default Schedule

The default interval for this script is Every 15 minutes.

80.11.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event? (y/n)	Set to **y** to raise an event if the percentage of the pool that is in use falls below the threshold. The default is y.
Collect data? (y/n)	Set to **y** to collect data for reports and graphs. The default is n.
Include results for individual data sources? (y/n)	Set to **n** to disable collection of data and event triggering for individual data sources, so that only aggregate data for the provider or connection pool is processed. The default is y. **NOTE:** If you run this Knowledge Script on an individual data source (rather than on the J2C Connection Pools node) and this parameter is set to n, the script will not perform any action.
Percent of pool in use threshold	Specify a threshold value using an integer greater than or equal to -1. Use -1 to ignore this threshold. If the percentage of the pool that is in use falls below this threshold, an event is raised. The default is -1.
Event severity when percent of pool in use falls below threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.

80.12 J2CWaits

Use this Knowledge Script to monitor the time spent waiting for J2C (Java 2 Connectivity) connections. This script records the average number of threads concurrently waiting for connections, the average time spent waiting for a connection, and the number of faults (usually connection timeouts) that have occurred.

80.12.1 Resource Object

J2C Connection Pool or a J2C Data Source

80.12.2 Default Schedule

The default interval for this script is Every 15 minutes.

80.12.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event? (y/n)	Set to **y** to raise an event if the threshold is exceeded. The default is y.
Collect data? (y/n)	Set to **y** to collect data for reports and graphs. The default is n.
Include results for individual data sources? (y/n)	Set to **n** to disable collection of data and event triggering for individual data sources, so that only aggregate data for the provider or connection pool is processed. The default is y. **NOTE:** If you run this Knowledge Script on an individual data source (rather than on the J2C Connection Pools node) and this parameter is set to n, the script will not perform any actions.
Threads currently awaiting a connection	Specify a threshold value using an integer greater than or equal to -1. Use -1 to ignore this threshold. If the number of threads currently waiting for a connection exceeds this threshold, an event is raised. The default is -1.
Event severity when threads currently awaiting a connection exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of threads currently waiting for a connection exceeds this threshold. The default is 25.
Average wait time threshold	Specify a threshold value greater than or equal to -1. Use -1 to ignore this threshold. If the average time (in seconds) spent waiting for a connection exceeds this threshold, an event is raised. The default is -1.
Event severity when average wait time exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the average time (in seconds) spent waiting for a connection exceeds the threshold. The default is 25.
Connection faults	Specify a threshold value using an integer greater than or equal to -1. Use -1 to ignore this threshold. If the number of faults exceeds this threshold, an event is raised. The default is 0.

Description	How to Set It
Event severity when connection faults exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of faults exceeds the threshold. The default is 25.

80.13 JDBCDriver

Use this Knowledge Script to monitor the amount of time, in seconds, that the JDBC data source spent running in the JDBC driver, which includes time spent in the JDBC driver, network, and database.

80.13.1 Resource Object

JDBC Connection Pool, or a JDBC Provider, or a JDBC Data Source

80.13.2 Default Schedule

The default interval for this script is Every 15 minutes.

80.13.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event? (y/n)	Set to **y** to raise an event if the amount of time (in seconds) spent executing in the JDBC driver exceeds the threshold. The default is y.
Collect data? (y/n)	Set to **y** to collect data for reports and graphs. The default is n.
Include results for individual providers? (y/n)	Set to **n** to aggregate event and data details for individual providers, so that only aggregate data for the connection pool is processed. The default is y. If you run this Knowledge Script on an individual provider or data source (rather than on the JDBC Connection Pools node) and this parameter is set to n, the script will not perform any actions unless the **Include results for individual data sources** parameter is set to y.
Include results for individual data sources? (y/n)	Set to **n** to disable collection of data and event triggering for individual data sources, so that only aggregate data for the provider or connection pool is processed. The default is y. **NOTE:** If you run this Knowledge Script on an individual data source (rather than on the JDBC Connection Pools node, or on a provider node) and this parameter is set to n, the script will not perform any actions.
Time spent executing in JDBC driver threshold	Specify a threshold value greater than or equal to -1. Use -1 to ignore this threshold. If amount of time (in seconds) spent executing in the JDBC driver exceeds this threshold, an event is raised. The default is -1.
Event severity when time spent in JDBC driver exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.

80.14 JDBCUsage

Use this Knowledge Script to monitor the Java Database Connectivity (JDBC) connection pool usage statistics. The script records the following data:

- The average percentage of the pool that is in use.
- The average percentage of the time that all connections in the pool are in use.
- The average time a connection is in use.
- The number of ManagedConnection objects that are in use.
- The number of connection handles that are in use.

80.14.1 Resource Object

JDBC Connection Pool, or a JDBC Provider, or a JDBC Data Source

80.14.2 Default Schedule

The default interval for this script is Every 15 minutes.

80.14.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event? (y/n)	Set to **y** to raise an event if the current percent of the pool that is in use falls below the threshold. The default is y.
Collect data? (y/n)	Set to **y** to collect data for reports and graphs. The default is n.
Include results for individual providers? (y/n)	Set to **n** to aggregate event and data details for individual providers, so that only aggregate data for the connection pool is processed. The default is y. If you run this Knowledge Script on an individual provider or data source (rather than on the JDBC Connection Pools node) and this parameter is set to n, the script will not perform any actions unless the **Include results for individual data sources** parameter is set to y.
Include results for individual data sources? (y/n)	Set to **n** to disable collection of data and event triggering for individual data sources, so that only aggregate data for the provider or connection pool is processed. The default is y. **NOTE:** If you run this Knowledge Script on an individual data source (rather than on the JDBC Connection Pools node, or on a provider node) and this parameter is set to n, the script will not perform any actions.
Current percent of pool in use threshold	Specify a threshold value using an integer greater than or equal to -1. Use -1 to ignore this threshold. If the current percent of the pool that is in use falls below this threshold, an event is raised. The default is -1.

Description	How to Set It
Event severity when current percent of pool in use exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.

80.15 JDBCWaits

Use this Knowledge Script to monitor the amount of time, in seconds, that a JDBC data source spent waiting for a JDBC connection. This script records the number of threads currently waiting for connections, the average time spent waiting for a connection, and the number of faults (usually connection timeouts) that have occurred.

80.15.1 Resource Object

JDBC Connection Pool, or a JDBC Provider, or a JDBC Data Source

80.15.2 Default Schedule

The default interval for this script is Every 15 minutes.

80.15.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event? (y/n)	Set to **y** to raise an event if a threshold is exceeded. The default is y.
Collect data? (y/n)	Set to **y** to collect data for reports and graphs. The default is n.
Include results for individual providers? (y/n)	Set to **n** to aggregate event and data details for individual providers, so that only aggregate data for the connection pool is processed. The default is y. **NOTE:** If you run this Knowledge Script on an individual provider or data source (rather than on the JDBC Connection Pools node) and this parameter is set to n, the script will not perform any actions unless the **Include results for individual data sources** parameter is set to y.
Include results for individual data sources? (y/n)	Set to **n** to disable collection of data and event triggering for individual data sources, so that only aggregate data for the provider or connection pool is processed. The default is y. **NOTE:** If you run this Knowledge Script on an individual data source (rather than on the JDBC Connection Pools node, or on a provider node) and this parameter is set to n, the script will not perform any actions.
Threads currently awaiting a connection threshold	Specify a threshold value using an integer greater than or equal to -1. Use -1 to ignore this threshold. If the number of threads currently waiting for a connection exceeds this threshold, an event is raised. The default is -1.
Event severity when threads currently awaiting a connection exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the threads currently awaiting a connection exceed the threshold. The default is 25.

Description	How to Set It
Average wait time threshold	Specify a threshold value greater than or equal to -1. Use -1 to ignore this threshold. If the average time (in seconds) spent waiting for a connection exceeds this threshold, an event is raised. The default is -1.
Event severity when average wait time exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the average time (in seconds) spent waiting for a connection exceeds the threshold. The default is 25.
Connection faults threshold	Specify a threshold value using an integer greater than or equal to -1. Use -1 to ignore this threshold. If the number of faults exceeds this threshold, an event is raised. The default is 0.
Event severity when connection faults exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of faults exceeds the threshold. The default is 25.

80.16 JVMGCStats

Use this Knowledge Script to monitor garbage collection statistics for objects in the Java Virtual Machine (JVM) heap. This script records the number of garbage collections, the average time between collections, and the average collection duration.

This Knowledge Script requires the JVM interface to be running

80.16.1 Resource Object

JVM Runtime

80.16.2 Default Schedule

The default interval for this script is Every 15 minutes.

80.16.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event? (y/n)	Set to **y** to raise an event if a threshold is exceeded. The default is y.
Collect data? (y/n)	Set to **y** to collect data for reports and graphs. The default is n.
Garbage collections threshold	Specify a threshold value using an integer greater than or equal to -1. Use -1 to ignore this threshold. If the number of garbage collections exceeds this threshold, an event is raised. The default is -1.
Event severity when garbage collections exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of garbage collections exceeds the threshold. The default is 25.
Average garbage collection duration threshold	Specify a threshold value greater than or equal to -1. Use -1 to ignore this threshold. If the average garbage collection duration (in seconds) exceeds this threshold, an event is raised. The default is -1.
Event severity when average garbage collection duration exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the average garbage collection duration (in seconds) exceeds the threshold. The default is 25.
Average time between calls threshold	Specify a threshold value greater than or equal to -1. Use -1 to ignore this threshold. If the average time (in seconds) between calls falls below this threshold, an event is raised. The default is -1.
Event severity when average time between calls falls below threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the average time (in seconds) between calls falls below the threshold. The default is 25.

80.17 JVMHeap

Use this Knowledge Script to monitor memory usage statistics of the application server's Java Virtual Machine (JVM) heap. This script reports the amount of free and used heap memory.

This Knowledge Script requires the JVM interface to be running.

80.17.1 Resource Object

JVM Runtime

80.17.2 Default Schedule

The default interval for this script is Every 15 minutes.

80.17.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event? (y/n)	Set to **y** to raise event if a threshold is exceeded. The default is y.
Collect data? (y/n)	Set to **y** to collect data for reports and graphs. The default is n.
Heap size threshold	Specify a threshold value using an integer greater than or equal to -1. Use -1 to ignore this threshold. If the current size of the heap in KB exceeds this threshold, an event is raised. The default is -1.
Event severity when heap size exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the current size of the heap in KB exceeds the threshold. The default is 25.
Free heap threshold	Specify a threshold value using an integer greater than or equal to -1. Use -1 to ignore this threshold. If the number of KB available in the heap falls below this threshold, an event is raised. The default is -1.
Event severity when free heap falls below threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of KB available in the heap falls below the threshold. The default is 25.
Percent heap used threshold	Specify a threshold value using an integer greater than or equal to -1. Use -1 to ignore this threshold. If the percentage of the JVM heap that is currently used exceeds this threshold, an event is raised. The default is -1.
Event severity percent heap used exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the percentage of the JVM heap that is currently used exceeds the threshold. The default is 25.

80.18 JVMLocks

Use this Knowledge Script to monitor Java Virtual Machine (JVM) lock statistics. This script records the number of times a thread waits for a lock, and the average wait time for a lock.

This Knowledge Script requires the JVM interface to be running

80.18.1 Resource Object

JVM Runtime

80.18.2 Default Schedule

The default interval for this script is Every 15 minutes.

80.18.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event? (y/n)	Set to **y** to raise an event if a threshold is exceeded. The default is y.
Collect data? (y/n)	Set to **y** to collect data for reports and graphs. The default is n.
Lock waits threshold	Specify a threshold value using an integer greater than or equal to -1. Use -1 to ignore this threshold. If the average number of lock waits exceeds this threshold, an event is raised. The default is -1.
Event severity when lock waits exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the average number of lock waits exceeds the threshold. The default is 25.
Average lock wait duration threshold	Specify a threshold value greater than or equal to -1. Use -1 to ignore this threshold. If the average duration of the wait for a lock (in seconds) exceeds this threshold, an event is raised. The default is -1.
Event severity when average lock wait duration exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the average duration of the wait for a lock (in seconds) exceeds the threshold. The default is 25.

80.19 JVMObjects

Use this Knowledge Script to monitor allocation statistics for objects in the Java Virtual Machine (JVM) heap. This script records the number of objects allocated, moved, and freed in the heap.

This Knowledge Script requires the JVM interface to be running

This Knowledge Script requires time to complete an iteration before starting a new one. Do not set the interval to be less than Every 5 minutes.

80.19.1 Resource Object

JVM Runtime

80.19.2 Default Schedule

The default interval for this script is Every 15 minutes.

80.19.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event? (y/n)	Set to **y** to raise an event if a threshold is exceeded. The default is y.
Collect data? (y/n)	Set to **y** to collect data for reports and graphs. The default is n.
Objects allocated threshold	Specify a threshold value using an integer greater than or equal to -1. Use -1 to ignore this threshold. If the number of objects allocated exceeds this threshold, an event is raised. The default is -1.
Event severity when objects allocated exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of objects allocated exceeds the threshold. The default is 25.
Objects moved threshold	Specify a threshold value using an integer greater than or equal to -1. Use -1 to ignore this threshold. If the number of objects moved exceeds this threshold, an event is raised. The default is -1.
Event severity when objects moved exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of objects moved exceeds the threshold. The default is 25.
Objects freed threshold	Specify a threshold value using an integer greater than or equal to -1. Use -1 to ignore this threshold. If the number of objects freed exceeds this threshold, an event is raised. The default is -1.
Event severity when objects freed exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of objects freed exceeds the threshold. The default is 25.

80.20 JVMThreads

Use this Knowledge Script to monitor Java Virtual Machine (JVM) thread creation and destruction. The script records the number of threads that start executing, and the number that finish executing.

This Knowledge Script requires the JVM interface to be running

80.20.1 Resource Object

JVM Runtime

80.20.2 Default Schedule

The default interval for this script is Every 15 minutes.

80.20.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event? (y/n)	Set to **y** to raise an event if the average number of threads started exceeds this threshold. The default is y.
Collect data? (y/n)	Set to **y** to collect data for reports and graphs. The default is n.
Threads started threshold	Specify a threshold value using an integer greater than or equal to -1. Use -1 to ignore this threshold. If the average number of threads started exceeds this threshold, an event is raised. The default is -1.
Event severity when threads started exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.

80.21 NetIQAgent

Use this Knowledge Script to start or stop the Java server that the AppManager managed object uses to communicate with WebSphere Application Server. This Java server must be running in order for WebSphere Application Server Knowledge Scripts to work properly.

Typically, you do not need to manually start or stop the Java server. The Java server starts automatically when you discover WebSphere Application Server.

If you encounter problems with WebSphere Application Server Knowledge Scripts collecting performance data, use this Knowledge Script to stop and restart the Java server.

When you discover WebSphere Application Server, you specify the port that the Java server uses to communicate with the managed object. You can use this Knowledge Script to update the communication port on the Java server without rediscovering WebSphere Application Server. To change the listening port for the Java server, you must stop and restart the Java server to apply your changes.

80.21.1 Resource Object

WebSphere Application Server

80.21.2 Default Schedule

The default interval for this script is Run Once.

80.21.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event? (y/n)	Set to **y** to raise an event if the Java server cannot be started or stopped. The default is y.
Event severity when agent cannot be started or stopped	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 10.
Start agent? (y/n)	Set to **y** to start the agent, or **n** to stop the agent. The default is y.
TCP port	Specify the TCP port to be used by the Java server when listening for requests. The same port should normally be specified for all computers on which the Java server runs. However, this is strictly required only if you intend to run the RequestMetrics Knowledge Script. The default TCP port is 4000.

80.22 ORBInterceptor

Use this Knowledge Script to monitor the processing time for each Object Request Broker (ORB) interceptor.

80.22.1 Resource Object

ORB, or an individual ORB interceptor

80.22.2 Default Schedule

The default interval for this script is Every 15 minutes.

80.22.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event? (y/n)	Set to **y** to raise an event if the time (in seconds) spent executing in the interceptor exceeds the threshold. The default is y.
Collect data? (y/n)	Set to **y** to collect data for reports and graphs. The default is n.
Include results for individual ORB interceptors? (y/n)	Set to **n** to disable collection of data and event triggering for individual interceptors, so that only aggregate data for the ORB is processed. The default is y. **NOTE:** If you run this Knowledge Script on an individual interceptor (rather than on the Object Request Broker node) and this parameter is set to **n**, the script will not perform any actions.
Processing time threshold	Specify a threshold value greater than or equal to -1. Use -1 to ignore this threshold. If the time (in seconds) spent executing in the interceptor exceeds this threshold, an event is raised. The default is -1.
Event severity when processing time exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.

80.23 ORBRequests

Use this Knowledge Script to monitor Object Request Broker (ORB) request statistics. This script records the average object reference lookup time, the number of requests received, and the average number of concurrent requests.

This Knowledge Script requires time to complete an iteration before starting a new one. Do not set the interval to be less than Every 5 minutes.

80.23.1 Resource Object

ORB

80.23.2 Default Schedule

The default interval for this script is Every 15 minutes.

80.23.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event? (y/n)	Set to **y** to raise an event if a threshold is exceeded. The default is y.
Collect data? (y/n)	Set to **y** to collect data for reports and graphs. The default is n.
Average reference lookup time threshold	Specify a threshold value greater than or equal to -1. Use -1 to ignore this threshold. If the average time (in seconds) to look up an object reference exceeds this threshold, an event is raised. The default is -1.
Event severity when average reference lookup time exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the average time (in seconds) to look up an object reference exceeds the threshold. The default is 25.
Requests received threshold	Specify a threshold value using an integer greater than or equal to -1. Use -1 to ignore this threshold. If the number of requests received exceeds this threshold, an event is raised. The default is -1.
Event severity when requests received exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of requests received exceeds the threshold. The default is 25.
Concurrent requests threshold	Specify a threshold value using an integer greater than or equal to -1. Use -1 to ignore this threshold. If the number of requests currently being processed exceeds this threshold, an event is raised. The default is -1.
Event severity when concurrent requests exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of requests currently being processed exceeds this threshold. The default is 25.

80.24 Report_HealthSummary

Use this Knowledge Script to generate a report showing the availability and response time characteristics of one or more WebSphere Application Servers. The availability and response time measurements are based on the results generated by running the HealthCheck Knowledge Script, so no results will be available if that script has not been run. The response time measurements are based on the response times produced by the servlet specified in the HealthCheck Knowledge Script. If you run this report against multiple servers for which different servlets were specified in HealthCheck jobs, the response time metrics for the servers may not be directly comparable.

80.24.1 Resource Object

WebSphereAppSrvUNIX sub-node of Report Agent node

80.24.2 Default Schedule

The default interval for this script is Run once.

80.24.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Data source	
Select computer(s)	Select the WebSphere Application Servers. Click Browse [...] to select from one to twenty-five views. Your subsequent selections are limited to computers or server groups that are visible in the selected views. Select one of the Filters options: View: Includes all computers in the views you selected. Computer: Select from individual computers in the views you selected. Server Group: Select from server groups in the views you selected. Selecting a server group includes all computers in that group.
Select time range	Click Browse [...] to set a specific or sliding time range for data included in your report.
Select peak weekday(s)	Click Browse [...] to select the days of the week to include in your report.
Aggregation by	Select the time period (Hour, Minute, or Day) by which the data in your report is aggregated. The default is Hour.
Aggregation interval	Select the interval between aggregations of the data in your report. This parameter uses the time period specified in the **Aggregation by** parameter to calculate the interval. The default is 1.

Description	How to Set It
Report component selection	
Include parameter card?	Set to **y** to include a table showing report parameters. The default is y.
Include Running detail table?	Set to **y** to include a table of Running results (whether the server was found to be running) in the report. The default is y.
Include Running chart?	Set to **y** to include a chart of Running results (whether the server was found to be running) in the report. The default is y.
Threshold on Running chart	Specify the threshold to be shown on the Running chart. Use -1 to indicate that no threshold is to be shown.
Include Servlet Response Time detail table?	Set to **y** to include a table of Servlet Response Time results in the report. The default is y.
Include Servlet Response Time chart?	Set to **y** to include a chart of Servlet Response Time results in the report. The default is y.
Units for Servlet Response Time chart	Specify the units to be used for the Servlet Response Time chart. The default is milliseconds.
Threshold on Servlet Response Time chart	Specify the threshold to be shown on the Servlet Response Time chart. Use -1 to indicate that no threshold is to be shown.
Report settings	
Customize chart appearance	Specify the type and attributes of chart(s) to be generated. A wide selection of chart types is available. The default is Ribbon.
Select report location	Choose the report filename. The default is WebSphereAppSrvUNIX_HealthSummary.
Add job ID to output folder name?	Set to **y** to include the report job ID in the report output folder name. The default is n.
Index-report Title	Choose the report title, author, company, component, description, expiration period, and custom fields. Defaults are: Title = WebSphereAppSrvUNIX Health Summary Author = NetIQ AppManager Company = Your company here Component = NetIQ AppManager 5.0 <Module> Description = WebSphereAppSrvUNIX Health Summary: Availability and Servlet Response Time. Expiration Period = Expires after 7 days Custom Field 1 = WebSphereAppSrv, UNIX, Health Summary Custom Field 2 = Availability and Servlet Response Time
Add time stamp to title	Set to **y** to include the time the report was generated in the report title. The default is n.
Event notification	
Generate event on success?	Set to **y** to raise an event when the report is successfully generated. The default is y.
Severity level for report success	Specify a severity level for the event raised when the report is generated successfully. The default is 35.

Description	How to Set It
Severity level for report with no data	Specify a severity level for the event raised when no data for the report is found within the selected time interval. The default is 25.
Severity level for report failure	Specify a severity level for the event raised when the report generation fails. The default is 5.

80.25 RequestMetrics

Use this Knowledge Script to monitor the amount of time a node spent processing a request. In a multi-node deployment, requests typically enter the system and create processes that fan out across several nodes within the distributed system. Use this script to gather and correlate data collected at each node of the system, in order to provide a breakdown of how much time is spent in different components of the request-processing pipeline.

Before using this Knowledge Script, you must run the SetRMFilters script to instruct WebSphere Application Server to collect metrics for requests that match a given set of patterns, such as client IP address, URL, or EJB method names. Once request metrics are enabled, WebSphere Application Server will write an entry to the trace log each time a matching HTTP request is received or a remote EJB method call is made. This script can then be used to gather and correlate these trace log entries.

In order for this script to gather request metrics, it must be provided with a list of the hosts from which data is to be collected. Normally, you should specify all hosts in the WebSphere Application Server domain, but you can restrict the data to a particular subset of nodes by specifying only those computers. You do not need to specify individual application servers on the selected computers-the log files for all of the known application servers on each computer will be analyzed.

This script measures the request-processing time for only those requests that entered the system at the node on which this script is run. Any request that enters the WebSphere Application Server network at an upstream node is ignored. Hence, run this script only on the node containing the entry point for request processing. This script can be set to raise an event if the average request-processing response time exceeds a specified threshold. The detail message associated with the event shows the breakdown of how much time was spent in each component. You can also specify that a data stream containing the average response time be written to the database.

80.25.1 Resource Object

WebSphere Application Server

80.25.2 Default Schedule

The default interval for this script is Every 15 Minutes.

80.25.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event? (y/n)	Set to **y** to raise events. The default is y.
Collect data? (y/n)	Set to **y** to collect data for reports and graphs. The default is n.
Semicolon-separated list of hosts from which to collect data	Specify the hosts from which request metrics data should be gathered. Normally, you should specify all hosts in the WebSphere Application Server domain.

Description	How to Set It
Request-processing time threshold	Specify a threshold value greater than or equal to -1. Use -1 to ignore this threshold. If the average time to process a request (in seconds) exceeds this threshold, an event is raised. The default is -1.
Event severity when the request-processing time exceeds the threshold?	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.

80.26 ServerCPU

Use this Knowledge Script to monitor the CPU utilization of the application server. On multiprocessor systems, the CPU utilization is the average over all CPUs.

80.26.1 Resource Object

WebSphere Application Server

80.26.2 Default Schedule

The default interval for this script is Every 15 Minutes.

80.26.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event? (y/n)	Set to **y** to raise events. The default is y.
Collect data? (y/n)	Set to **y** to collect data for reports and graphs. The default is n.
Average CPU utilization threshold	Specify a threshold value using an integer greater than or equal to -1. Use -1 to ignore this threshold. If the CPU utilization of WebSphere Application Server exceeds this threshold, an event is raised. The default is 90.
Event severity when average CPU utilization exceeds threshold	Set the event severity level, from 1 to 40, to indicate event importance. The default is 25.

80.27 ServerScanLog

Use this Knowledge Script to monitor the server's primary Java Virtual Machine (JVM) log file. The script scans the log file for any lines written since the last iteration of the script that match the given inclusion filter and do not match the given exclusion filter. If the number of lines that pass this filtering exceeds a specified threshold, an event is raised. The detailed message associated with the event contains the matching lines.

The inclusion and exclusion filters are Perl regular expressions. Because the application server writes log entries in a specific format, a simple inclusion filter can be used to scan for errors of a specific type. For example, to scan for error entries, use an exclusion filter of `"\sE\s"`. For fatal errors, replace 'E' with 'F'. For warnings, use 'W'.

In addition to raising an event when a threshold is exceeded, this script records a data stream for the number of matching lines.

80.27.1 Resource Object

WebSphere Application Server

80.27.2 Default Schedule

The default interval for this script is Every 15 Minutes.

80.27.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event? (y/n)	Set to **y** to raise events. The default is y.
Collect data? (y/n)	Set to **y** to collect data for reports and graphs. The default is n.
Event severity when the log file does not exist	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 20.
Log entries matched threshold	Specify a threshold value using an integer greater than or equal to -1. Use -1 to ignore this threshold. If the number of log entries that match the search criteria exceeds this threshold, an event is raised. The default is 0.
Event severity when log entries matched exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Inclusion filter	Set to a string that is a Perl regular expression. Lines matching this expression pass the filter unless they also match the exclusion filter. The default is a null string.
Ignore case in inclusion filter matching? (y/n)	Set to **y** to ignore case when matching lines against the inclusion filter. The default is n.
Exclusion filter	Set to a string that is a Perl regular expression. Lines matching this expression are never returned, even if they pass the inclusion filter. The default is a null string.

Description	How to Set It
Ignore case in exclusion filter matching? (y/n)	Set to **y** to ignore case when matching lines against the exclusion filter. The default is n.

80.28 ServletErrors

Use this Knowledge Script to monitor errors generated by a servlet, or by the N servlets with the highest, or lowest, number of errors.

80.28.1 Resource Object

Web application or servlet

80.28.2 Default Schedule

The default interval for this script is Every 15 minutes.

80.28.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event? (y/n)	Set to **y** to raise events. The default is y.
Collect data? (y/n)	Set to **y** to collect data for reports and graphs. The default is n.
Number of servlets	Specify the number of servlets for which data should be collected. Use -1 (or 0) to indicate that all servlets should be processed. The default is 5.
Sort order	Set to **descending** to sort the servlets in decreasing order. Set to **ascending** to sort in ascending order. The default is descending.
Errors threshold	Specify a threshold value using an integer greater than or equal to -1. Use -1 to ignore this threshold. If the number of errors exceeds this threshold, an event is raised. The default is 0.
Event severity when errors exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.

80.29 ServletRequests

Use this Knowledge Script to monitor servlet requests and response times. This script records the number of requests received, the number of concurrent requests, and the average time taken to service a request. You can run this script against a single servlet, or you can run it against a Web application to get results for the servlets with the worst, or best, value for a specified performance metric.

80.29.1 Resource Object

Web application or servlet

80.29.2 Default Schedule

The default interval for this script is Every 15 minutes.

80.29.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event? (y/n)	Set to **y** to raise events. The default is y.
Collect data? (y/n)	Set to **y** to collect data for reports and graphs. The default is n.
Number of servlets	Specify the number of servlets for which data should be collected. Use -1 (or 0) to collect data for all servlets. The default is 5.
Sort by	Specify the performance metric by which servlets are sorted. The default is Response Time.
Sort order	Set to **descending** to sort the servlets in decreasing order; set to **ascending** to sort in ascending order. The default is descending.
Requests received threshold	Specify a threshold value using an integer greater than or equal to -1. Use -1 to ignore this threshold. If the number of requests received exceeds this threshold, an event is raised. The default is -1.
Event severity when requests received exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Concurrent requests threshold	Specify a threshold value using an integer greater than or equal to -1. Use -1 to ignore this threshold. If the number of concurrent requests exceeds this threshold, an event is raised. The default is -1.
Event severity when concurrent requests exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Average request processing time threshold	Specify a threshold value greater than or equal to -1. Use -1 to ignore this threshold. If the average time (in seconds) required to service a request exceeds this threshold, an event is raised. The default is -1.
Event severity when average request processing time exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.

80.30 SessionErrors

Use this Knowledge Script to monitor the following HTTP session errors:

- Requests received for sessions that were last accessed from another Web application, which might indicate either failover processing or a corrupt plug-in configuration.
- Requests for a new session that could not be processed because the threshold for the maximum number of sessions is exceeded. This applies only to sessions in memory with `AllowOverflow = false`.

80.30.1 Resource Object

Session Manager

80.30.2 Default Schedule

The default interval for this script is Every 15 minutes.

80.30.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event? (y/n)	Set to **y** to raise events. The default is **y**.
Collect data? (y/n)	Set to **y** to collect data for reports and graphs. The default is n.
Requests from unexpected source threshold	Specify a threshold value using an integer greater than or equal to -1. Use -1 to ignore this threshold. If the number of requests from a different source than the most recent session request exceeds this threshold, an event is raised. The default is -1.
Event severity when requests from unexpected source exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
New session request failures threshold	Specify a threshold value using an integer greater than or equal to -1. Use -1 to ignore this threshold. If the number of requests that fail because the session pool is full exceeds this threshold, an event is raised. The default is -1.
Event severity when new session requests failures exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.

80.31 SessionInvalid

Use this Knowledge Script to monitor HTTP session invalidation statistics. This script records the following data:

- The number of sessions that were invalidated.
- The number of sessions that were invalidated due to a timeout.
- The number of requests for a session that no longer exists, presumably because the session timed out.

80.31.1 Resource Object

Session Manager

80.31.2 Default Schedule

The default interval for this script is Every 15 minutes.

80.31.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event? (y/n)	Set to **y** to raise events. The default is y.
Collect data? (y/n)	Set to **y** to collect data for reports and graphs. The default is n.
Percent invalidated due to timeout threshold	Specify a threshold value using an integer greater than or equal to -1. Use -1 to ignore this threshold. If the percent of invalidated sessions that were invalidated due to a timeout exceeds this threshold, an event is raised. The default is -1.
Event severity when percent invalidated due to timeout exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Requests for nonexistent session threshold	Specify a threshold value using an integer greater than or equal to -1. Use -1 to ignore this threshold. If the average number of requests for sessions that do not exist exceeds this threshold, an event is raised. The default is -1.
Event severity when requests for nonexistent session exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.

80.32 SessionLifetime

Use this Knowledge Script to monitor HTTP sessions. This script records the following data:

- The number of sessions created.
- The average lifetime of a session.
- The average number of active sessions.
- The number of live (cached in memory) sessions.

80.32.1 Resource Object

Session Manager

80.32.2 Default Schedule

The default interval for this script is Every 15 minutes.

80.32.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event? (y/n)	Set to **y** to raise events. The default is y.
Collect data? (y/n)	Set to **y** to collect data for reports and graphs. The default is n.
Sessions created threshold	Specify a threshold value using an integer greater than or equal to -1. Use -1 to ignore this threshold. If the number of sessions created exceeds this threshold, an event is raised. The default is -1.
Event severity when sessions created exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Average session lifetime threshold	Specify a threshold value greater than or equal to -1. Use -1 to ignore this threshold. If average session lifetime (in seconds) exceeds this threshold, an event is raised. The default is -1.
Event severity when average session lifetime exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Current active sessions threshold	Specify a threshold value using an integer greater than or equal to -1. Use -1 to ignore this threshold. If the current number of active sessions exceeds this threshold, an event is raised. The default is -1.
Event severity when current active sessions exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Current live sessions threshold	Specify a threshold value using an integer greater than or equal to -1. Use -1 to ignore this threshold. If the current number of live sessions exceeds this threshold, an event is raised. The default is -1.
Event severity when current live sessions exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.

80.33 SetRMFilters

Use this Knowledge Script to specify the filters to be used for generating request metrics traces. You must specify filters using this script before you can collect response time data with the RequestMetrics Knowledge Script. Three types of filtering can be specified, as described below. In each case, the filter pattern is expressed as a string that can optionally contain an asterisk (*) as the last character. Matching is done character by character, until either an asterisk is found in the filter, a mismatch occurs, or an exact match occurs.

- URL filters: Requests are filtered based on the URL of the incoming HTTP request.
- Client IP address filters: Requests are filtered based on the IP address of the incoming HTTP request.
- EJB method name filters: Requests are filtered based on the full name of the enterprise bean method.

If both URL filters and client IP address filters are specified, a match occurs only if a filter of each type is matched. It is strongly suggested that at least one URL or client IP address filter be supplied, to avoid performance degradation due to the large number of trace records that otherwise would be written to the trace log.

If no filters are specified, this script turns off request metrics tracing altogether. That is, it has the effect of stopping request metrics tracing completely, rather than causing all requests to be traced. Thus, to turn on request metrics tracing, you must specify at least one filter. If you do not plan to run the RequestMetrics Knowledge Script on any computer in the WebSphere Application Server domain for a long period of time, you can turn off tracing by specifying no filters to avoid the performance penalty engendered by writing request traces to the log file.

NOTE: In an IBM WebSphere Application Server network deployment, the Request Metrics configuration is managed centrally by the deployment manager, and the settings apply to all nodes and application servers in the cell. Therefore, you only need to run this Knowledge Script against a single server in the deployment cell.

80.33.1 Resource Object

WebSphere Application Server

80.33.2 Default Schedule

The default interval for this script is Run Once.

80.33.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event? (y/n)	Set to **y** to raise events. The default is y.
Semicolon-separated list of URL filters	Specify the URL patterns to be used in filtering. Patterns should be separated from one another by semicolons.
Semicolon-separated list of client IP address filters	Specify the IP address patterns to be used in filtering. Patterns should be separated from one another by semicolons.
Semicolon-separated list of EJB method name filters	Specify the EJB method name patterns to be used in filtering. Patterns should be separated from one another by semicolons.

80.34 SetServerLogPath

Use this Knowledge Script to specify the pathname of the server's primary Java Virtual Machine (JVM) log file. The JVM log contains messages written by the application server JVM itself, as well as by applications running within the server. If the JVM log file is being written to the default location, it is not necessary to run this script. However, if the JVM log file is being written to a different directory or has a different filename than the default, you must run this script before attempting to scan the log files using the ServerScanLog Knowledge Script. Failing to do so will cause ServerScanLog to raise an event when it is run.

In addition, to enable the RequestMetrics Knowledge Script to work properly, you must set the server log path because the RequestMetrics Knowledge Script collects traces from the server log file as well.

80.34.1 Resource Object

WebSphere Application Server

80.34.2 Default Schedule

The default interval for this script is Run Once.

80.34.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event? (y/n)	Set to **y** to raise events. The default is y.
Path name for WebSphere JVM log file	Specify the path to the server's primary JVM log file, SystemOut.log, either as an absolute path, or a path relative to the `WebSphere/AppServer` directory. Replace any spaces in the path name with an underscore.
Event severity when the log file does not exist	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 20.

80.35 StartServer

Use this Knowledge Script to start the WebSphere Application Server. Starting an application server starts a server process based on the application server's configuration.

If WebSphere Application Server security is enabled, you must use AppManager Security Manager to update the AppManager repository to provide the WebSphere Application Server account information that is required to start the application server.

If you are running the agent with a non-root account on WebSphere Application Server 8.0 or 8.5, ensure you have applied all required WebSphere Application Server fixes to start the server. Refer to the IBM support site regarding this problem http://www.ibm.com/support/docview.wss?uid=swg1PM63269/.

80.35.1 Resource Object

WebSphere Application Server

80.35.2 Default Schedule

The default interval for this script is Run Once.

80.35.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event? (y/n)	Set to **y** to raise events. The default is y.
Event severity when application server cannot be started	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 10.
Event severity when application server is started successfully	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Start time limit	Set to the number of seconds within which the WebSphere Application Server should complete initialization. The default is 300.

80.36 StopServer

Use this Knowledge Script to stop the WebSphere Application Server. Stopping an application server stops a server process based on the process definition settings in the current application server configuration.

If WebSphere Application Server security is enabled, you must use AppManager Security Manager to update the AppManager repository to provide the WebSphere Application Server account information that is required to start the application server.

80.36.1 Resource Object

WebSphere Application Server

80.36.2 Default Schedule

The default interval for this script is Run Once.

80.36.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event? (y/n)	Set to **y** to raise events. The default is y.
Event severity when the server cannot be stopped	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 15.
Event severity when the server is stopped successfully	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Stop time limit	Set to the number of seconds within which the WebSphere Application Server should stop running. The default is 300.

80.37 ThreadPoolUsage

Use this Knowledge Script to monitor thread pool activity. This script records the following:

- The number of threads created.
- The number of threads destroyed.
- The number of active threads.
- The thread pool size.
- The percentage of time that all threads in the pool are in use.

This Knowledge Script requires time to complete an iteration before starting a new one. Do not set the interval to be less than Every 5 minutes.

80.37.1 Resource Object

Thread Pools, or a particular thread pool

80.37.2 Default Schedule

The default interval for this script is Every 15 minutes.

80.37.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event? (y/n)	Set to **y** to raise events. The default is y.
Collect data? (y/n)	Set to **y** to collect data for reports and graphs. The default is n.
Include results for individual thread pools? (y/n)	Set to **n** to disable collection of data and event triggering for individual thread pools, so that only aggregate data for all thread pools is processed. The default is y. **NOTE:** If you run this Knowledge Script on an individual thread pool (rather than on the Thread Pools node) and this parameter is set to **n**, the script will not perform any actions.
Active threads threshold	Specify a threshold value using an integer greater than or equal to -1. Use -1 to ignore this threshold. If the number of active threads exceeds this threshold, AppManager raises an event. The default is -1.
Event severity when active threads exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Pool size threshold	Specify a threshold value using an integer greater than or equal to -1. Use -1 to ignore this threshold. If the current pool size exceeds this threshold, AppManager raises an event. The default is -1.

Description	How to Set It
Event severity when pool size exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Percent of time all threads are in use threshold	Specify a threshold value using an integer greater than or equal to -1. Use -1 to ignore this threshold. If the percentage of time that all threads in the pool are in use exceeds this threshold, an event is raised. The default is -1.
Event severity when percent of time all threads are in use exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.

80.38 TransactionCommits

Use this Knowledge Script to monitor the number of commits, rollbacks and timeouts, for both local and global transactions.

80.38.1 Resource Object

Transaction Manager

80.38.2 Default Schedule

The default interval for this script is Every 15 minutes.

80.38.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event? (y/n)	Set to **y** to raise events. The default is y.
Collect data? (y/n)	Set to **y** to collect data for reports and graphs. The default is n.
Global transaction commits threshold	Specify a threshold value using an integer greater than or equal to -1. Use -1 to ignore this threshold. If the number of global transaction commits exceeds this threshold, an event is raised. The default is -1.
Event severity when global transaction commits exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Global transaction rollbacks threshold	Specify a threshold value using an integer greater than or equal to -1. Use -1 to ignore this threshold. If the number of global transaction rollbacks exceeds this threshold, an event is raised. The default is -1.
Event severity when global transaction rollbacks exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Global transaction timeouts threshold	Specify a threshold value using an integer greater than or equal to -1. Use -1 to ignore this threshold. If the number of global transaction timeouts exceeds this threshold, an event is raised. The default is -1.
Event severity when global transaction timeouts exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Local transaction commits threshold	Specify a threshold value using an integer greater than or equal to -1. Use -1 to ignore this threshold. If the number of local transaction commits exceeds this threshold, an event is raised. The default is -1.
Event severity when local transaction commits exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.

Description	How to Set It
Local transaction rollbacks threshold	Specify a threshold value using an integer greater than or equal to -1. Use -1 to ignore this threshold. If the number of local transaction rollbacks exceeds this threshold, an event is raised. The default is -1.
Event severity when local transaction rollbacks exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Local transaction timeouts threshold	Specify a threshold value using an integer greater than or equal to -1. Use -1 to ignore this threshold. If the number of local transaction timeouts exceeds this threshold, an event is raised. The default is -1.
Event severity when local transaction timeouts exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.

80.39 TransactionDuration

Use this Knowledge Script to monitor the average transaction duration, as well as the duration of transaction prepares and commits, for both local and global transactions.

80.39.1 Resource Object

Transaction Manager

80.39.2 Default Schedule

The default interval for this script is Every 15 minutes.

80.39.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event? (y/n)	Set to **y** to raise events. The default is y.
Collect data? (y/n)	Set to **y** to collect data for reports and graphs. The default is n.
Global transactions threshold	Specify a threshold value using an integer greater than or equal to -1. Use -1 to ignore this threshold. If the number of global transactions exceeds this threshold, an event is raised. The default is -1.
Event severity when global transactions exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Average global transaction duration threshold	Specify a threshold value greater than or equal to -1. Use -1 to ignore this threshold. If the average global transaction duration (in seconds) exceeds this threshold, an event is raised. The default is -1.
Event severity when average global transaction duration exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Local transactions threshold	Specify a threshold value using an integer greater than or equal to -1. Use -1 to ignore this threshold. If the number of local transactions exceeds this threshold, an event is raised. The default is -1.
Event severity when local transactions exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Average local transaction duration threshold	Specify a threshold value greater than or equal to -1. Use -1 to ignore this threshold. If the average local transaction duration (in seconds) exceeds this threshold, an event is raised. The default is -1.
Event severity when average local transaction duration exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.

80.40 WebAppLoads

Use this Knowledge Script to monitor the number of servlets loaded and reloaded for a particular Web application, or for the top N Web applications, sorted by a specified metric.

80.40.1 Resource Object

Web Applications, or a particular Web application

80.40.2 Default Schedule

The default interval for this script is Every 15 minutes.

80.40.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event? (y/n)	Set to **y** to raise events. The default is y.
Collect data? (y/n)	Set to **y** to collect data for reports and graphs. The default is n.
Number of Web applications	Specify the number of Web applications for which data should be collected. Use –1 (or 0) to indicate that all Web applications should be processed.
Sort by	Specify the performance metric by which Web applications are sorted.
Sort order	Set to **descending** to sort the Web applications in decreasing order; set to **ascending** to sort in ascending order. The default is **descending**.
Servlets loaded threshold	Specify a threshold value using an integer greater than or equal to -1. Use -1 to ignore this threshold. If the number of servlets loaded exceeds this threshold, an event is raised. The default is -1.
Event severity when servlets loaded exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Servlets reloaded threshold	Specify a threshold value using an integer greater than or equal to -1. Use -1 to ignore this threshold. If the number of servlets reloaded exceeds this threshold, an event is raised. The default is -1.
Event severity when servlets reloaded exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.

80.41 WLMClientRequests

Use this Knowledge Script to monitor the outgoing request-processing statistics for the Workload Manager. The script records the following data:

- The number of outgoing requests processed.
- The average response time required to service those requests.

80.41.1 Resource Object

Workload Manager (Client)

80.41.2 Default Schedule

The default interval for this script is **Every 15 minutes.**

80.41.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event? (y/n)	Set to **y** to raise events. The default is y.
Collect data? (y/n)	Set to **y** to collect data for reports and graphs. The default is n.
Outgoing requests threshold	Specify a threshold value using an integer greater than or equal to -1. Use -1 to ignore this threshold. If the number of outgoing requests exceeds this threshold, an event is raised. The default is -1.
Request response time threshold	Specify a threshold value using an integer greater than or equal to -1. Use -1 to ignore this threshold. If the average response time exceeds this threshold, an event is raised. The default is -1.
Event severity when request response time exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.

80.42 WLMServerRequests

Use this Knowledge Script to monitor the request-processing statistics for the Workload Manager. The script records the following data:

- The number of requests currently being processed.
- The number of requests processed.
- The average number of requests processed that have a strong affinity to the server. A strong affinity request is one that must be serviced by this application server because of a dependency that resides on the server. One example of this is transactional affinity.
- The average number of requests processed that do not have a strong affinity to the server.
- The average number of requests processed that came from a non-WLM enabled client, or were marked by the client not to participate in workload management.

80.42.1 Resource Object

Workload Manager Server

80.42.2 Default Schedule

The default interval for this script is Every 15 minutes.

80.42.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event? (y/n)	Set to **y** to raise events. The default is y.
Collect data? (y/n)	Set to **y** to collect data for reports and graphs. The default is n.
Concurrent requests threshold	Specify a threshold value using an integer greater than or equal to -1. Use -1 to ignore this threshold. If the number of concurrent requests exceeds this threshold, an event is raised. The default is -1.
Event severity when concurrent requests exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Strong affinity request percent threshold	Specify a threshold value using an integer greater than or equal to -1. Use -1 to ignore this threshold. If the percent of requests that have a strong affinity to the server exceeds this threshold, an event is raised. The default is -1.
Event severity when strong affinity request percent exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.

80.43 WSGWRequests

Use this Knowledge Script to monitor requests received and responses sent by a Web service.

80.43.1 Resource Object

Web Services or a particular Web service

80.43.2 Default Schedule

The default interval for this script is Every 15 minutes.

80.43.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event? (y/n)	Set to **y** to raise events. The default is y.
Collect data? (y/n)	Set to **y** to collect data for reports and graphs. The default is n.
Synchronous requests received threshold	Specify a threshold value using an integer greater than or equal to -1. Use -1 to ignore this threshold. If the number of synchronous requests received exceeds this threshold, an event is raised. The default is -1.
Event severity when synchronous requests received exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Synchronous responses sent threshold	Specify a threshold value using an integer greater than or equal to -1. Use -1 to ignore this threshold. If the number of synchronous responses made exceeds this threshold, an event is raised. The default is -1.
Event severity when synchronous responses sent exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Asynchronous requests received threshold	Specify a threshold value using an integer greater than or equal to -1. Use -1 to ignore this threshold. If the number of asynchronous requests received exceeds this threshold, an event is raised. The default is -1.
Event severity when asynchronous requests received exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.
Asynchronous responses sent threshold	Specify a threshold value using an integer greater than or equal to -1. Use -1 to ignore this threshold. If the number of asynchronous responses made exceeds this threshold, an event is raised. The default is -1.
Event severity when asynchronous responses sent exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 25.

81 WebSphere MQ UNIX Knowledge Scripts

AppManager provides the following Knowledge Scripts for monitoring IBM WebSphere MQ Servers running on UNIX operating systems.

From the AppManager consoles, you can select a Knowledge Script and press **F1** for complete details.

Knowledge Script	What It Does
ADMINClearLocalQueue	Clears local queue messages.
ADMINQueueMgrStartStop	Sends a command to the WebSphere MQ Server to start or stop a queue manager.
ChannelStatus	Monitors the status of WebSphere MQ channels.
DynamicLocalQueueDepth	Monitors the depth of local queues, including dynamically created queues.
LocalQueueDepth	Monitors the total number of messages in discovered local queues.
PingQueueManager	Pings a local queue manager and restarts the command server or queue manager if either is detected down.
ServerDown	Monitors processes that belong to a specified WebSphere MQ Server user group.
TestQueueManager	Monitors the connection between the WebSphere MQ Server and a local queue manager.
WebSphereMQErrorLog	Monitors the WebSphere MQ error log file for specific strings and messages logged since the last monitoring interval.

81.1 ADMINClearLocalQueue

Use this Knowledge Script to clear local queue messages. This Knowledge Script clears the local queue of any messages when the local queue depth exceeds the specified threshold.

Alternatively, you can configure this Knowledge Script to clear the local queue each time the Knowledge Script job runs, regardless of how many messages are in the local queue.

AppManager raises an event if the local queue cannot be cleared.

This Knowledge Script makes WebSphere MQ Server easier to administer because it can be used to clear several local queues at once.

81.1.1 Resource Object

MQSeries queue.

81.1.2 Default Schedule

The default interval for this Knowledge Script is **Run once**.

81.1.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Local queue message depth threshold	Enter a threshold for the maximum number of messages, from 0 to 6400, in a local queue. If the threshold is exceeded, the local queue is cleared. The default is 5.
Clear all messages regardless of queue depth?	Set to **y** to ensure that a threshold cannot be set and all messages in the local queue are cleared regardless of queue depth. The default is n.
Event severity if queue manager or command server is down	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 5.

81.2 ADMINQueueMgrStartStop

Use this Knowledge Script to send a command to the WebSphere MQ Server to start or stop a queue manager. This Knowledge Script verifies that the command completed successfully.

This Knowledge Script makes WebSphere MQ Server easier to administer, because it can start or stop several queue managers at once.

81.2.1 Resource Object

MQSeries queue manager.

81.2.2 Default Schedule

The default interval for this Knowledge Script is **Run once**.

81.2.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Start queue manager? (y/n)	Set to **y** to start a queue manager. The default is y.
Stop queue manager? (y/n)	Set to **y** to stop a queue manager. The default is n.
Time to wait before checking command results	Enter the number of seconds, from 0 to 9999, for the Knowledge Script to wait before attempting to confirm that a start or stop command completed successfully. When specifying this value, consider the following: • The system resources available to WebSphere MQ Server. • It takes longer to stop a queue manager than to start a queue manager. If the amount of time you specify is insufficient for the queue manager to start or stop, the status of the queue manager is not confirmed and AppManager raises an event. The default is 30 seconds.
Event severity if command...	Set the event severity level, from 1 to 40, to indicate the importance if the command: ... fails. The default is 5. ... succeeds. The default is 12.

81.3 ChannelStatus

Use this Knowledge Script to monitor the status of WebSphere MQ channels. AppManager raises an event when the channel is inactive, stopped, paused, or running.

If AppManager cannot retrieve the status of a channel because the channel is not initialized correctly, AppManager raises an event with an event message that includes a WebSphere MQ internal code describing the problem. You can use this information to locate the origin of the problem.

81.3.1 Resource Object

MQSeries channels.

81.3.2 Default Schedule

The default interval for this Knowledge Script is **Every 5 minutes**.

81.3.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event if channel is...	Set to **y** to raise an event if the channel status is: ... inactive. The default is y. ... stopped. The default is y. ... paused. The default is y. ... running. The default is n. ... binding. The default is n. ... starting. The default is n. ... stopping. The default is n. ... retrying. The default is n. ... requesting. The default is n. ... initializing. The default is n. ... not found. The default is n.
Collect Data?	Set to **y** to collect data for graphs and reports. The default is **n**. If set to **y**, the script returns a value of: • **100** if the channel is running. • **50** if the channel is binding, starting, stopping, retrying, requesting, or initializing. • **25** if the channel is inactive, stopped, or paused. • **0** if the channel status cannot be retrieved.

Description	How to Set It
Event severity if channel...	Set the event severity level, from 1 to 40, to reflect the importance when the channel status is: ... inactive. The default is 5. ... stopped. The default is 5. ... paused. The default is 5. ... running. The default is 25. ... status cannot be retrieved. The default is 25. ... binding. The default is 25. ... starting. The default is 25. ... stopping. The default is 25. ... retrying. The default is 25. ... requesting. The default is 25. ... initializing. The default is 25. ... not found. The default is 25.

81.4 DynamicLocalQueueDepth

Use this Knowledge Script to monitor the total number of messages in any specified local queue. AppManager raises an event if the number of messages in a queue exceeds the threshold you specify or the queue threshold specified in WebSphere MQ Explorer.

This Knowledge Script monitors an implementation of WebSphere MQ in which local queues are created and deleted dynamically. This Knowledge Script specifies queue names, does not raise events for queues that have already been deleted, and can monitor queues created since AppManager discovery was last run. For these reasons, the DynamicLocalQueueDepth Knowledge Script functions more efficiently than LocalQueueDepth for a dynamic implementation of WebSphere MQ.

If necessary, adjust the schedule to reflect the rate at which local queues are created and deleted.

81.4.1 Resource Object

MQSeries queue manager.

81.4.2 Default Schedule

The default interval is **Every 5 minutes**.

81.4.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event? (y/n)	Set to **y** to raise events. The default is y.
Queue name search criteria	Enter the queue name you want to monitor. The asterisk can be used as a wildcard. For example, the default (SYS*) monitors all system local queues. Queue names are case-sensitive.
Use queue's own threshold? (y/n)	Set to **y** to use the queue threshold defined in the queue's local attributes. AppManager raises an event if the threshold is met or exceeded. The default is n.
Local queue message depth threshold	If you do not want to use the queue's own threshold, enter a threshold for the maximum number of messages in the local queues being monitored. AppManager raises an event if the threshold is met or exceeded. The default is 5.
Event severity if queue manager or command server is down	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 5.

81.5 LocalQueueDepth

Use this Knowledge Script to monitor the total number of messages in the local queues. AppManager raises an event if the number of queue messages exceeds the threshold. You can define the threshold by the following:

- The number of messages set by the user.
- The queue's own threshold.
- The percentage of the queue's maximum depth represented by the number of messages in the queue (also called the percentage high).

This script monitors static implementations of WebSphere MQ in which local queues remain fixed. For the monitoring of dynamic implementations of WebSphere MQ, use DynamicLocalQueueDepth (which specifies queue names), because that script does not raise events for queues that were discovered by AppManager but have already been deleted.

81.5.1 Resource Object

MQSeries queue.

81.5.2 Default Schedule

The default interval is **Every 5 minutes**.

81.5.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event? (y/n)	Set to **y** to raise events. The default is y.
Collect data? (y/n)	Set to **y** to collect data for graphs and reports. The default is n. If set to **y**, the script returns the number of messages in the local queue.
Event if message queue is over threshold (-1 disables)	Specify a number of messages in the queue to raise an event when the number of messages reach that threshold. If you do not want AppManager to raise an event for this criteria, enter -1. The default is 5.
Event if message queue is over percentage utilization (-1 disables)	Specify a percent of the queue's maximum depth to raise an event when the depth reaches that percentage. If you do not want AppManager to raise an event based on this criteria, enter -1. The default is 90%.
Event severity if queue manager or command server is down	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 5.

81.6 PingQueueManager

Use this Knowledge Script to ping a local queue manager. AppManager raises an event when the queue manager or the command server is detected down, and the Knowledge Script then attempts to restart the command server or queue manager.

81.6.1 Resource Object

MQSeries queue manager.

81.6.2 Default Schedule

The default interval is **Every 5 minutes**.

81.6.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event? (y/n)	Set to **y** to raise events. The default is y.
Collect data? (y/n)	Set to **y** to collect data for graphs and reports. The default is n. If set to **y**, the script returns a value of 100 if the queue manager is up, or a value of 0 if it is down.
Restart queue manager if down? (y/n)	Set to **y** to automatically restart the queue manager if it is detected down. The command server will also automatically be restarted if this option is set to **y**. The default is y.
Event Severity if queue manager or command server...	Set the event severity level, from 1 to 40, to reflect the importance when the queue manager or command server: ... is down. The default is 5. ... restarted successfully. The default is 12.

81.7 ServerDown

Use this Knowledge Script to monitor processes that belong to a specified WebSphere MQ Server user group. AppManager raises an event when there are no processes that belong to the specified WebSphere MQ Server user group.

81.7.1 Resource Object

WebSphereMQUNIX Server.

81.7.2 Default Schedule

The default interval for this script is **Every 30 minutes**.

81.7.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event if over the threshold? (y/n)	Set to **y** to raise an event if the server is down or the number of processes that belong to the specified user group is 0. The default is y.
Collect data? (y/n)	Set to **y** to collect data for charts and reports. If set to **y**, this script returns the number of processes belonging to the specified user group running on the server. The default is n.
WebSphere MQ Server user group	Enter the name of the WebSphere MQ Server user group. The default is `mqm`.
Event severity level	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 5.

81.8 TestQueueManager

Use this Knowledge Script to monitor the connection between the WebSphere MQ Server and a local queue manager. AppManager raises an event if the WebSphere MQ Server fails to connect to the local queue manager.

This Knowledge Script only establishes that there is a connection between a queue manager and the WebSphere MQ Server. It does not monitor the status of the command server or send any messages to queues. If you need to monitor the command server, or restart either the command server or the local queue manager, use the PingQueueManager Knowledge Script instead.

81.8.1 Resource Object

MQSeries queue manager.

81.8.2 Default Schedule

The default interval is **Every 10 seconds**.

81.8.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event? (y/n)	Set to **y** to raise an event if the connection between a local queue manager and the WebSphere MQ Server fails. The default is y.
Collect data? (y/n)	Set to **y** to collect data for reports and graphs. The default is n. If set to **y**, the script returns a value of 100 if the queue manager connection is up, or a value of 0 if it is down. The default is n.
Event severity if queue manager or command server is down	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 5.

81.9 WebSphereMQErrorLog

Use this Knowledge Script to monitor the WebSphere MQ error log file for specific strings and messages logged since the last monitoring interval. This Knowledge Script allows you to specify the filename and a regular expression to identify the string to look for or to exclude. The Knowledge Script then scans the ASCII file and reports the matching entries found since the last monitoring period and checks for changes to the text file that match the expression you enter. The Knowledge Script does not re-scan the entire file at each interval.

In the first interval, this Knowledge Script reads the file and inserts a marker at the end of the file. In subsequent intervals, the script checks the file for changes that match the search criteria you specified. If the file is recreated between intervals and the file size is smaller than the previous version of the file, the script treats the file as a new file and searches the entire file from the beginning. AppManager raises an event when the number of lines matching your search criteria exceeds the threshold you set.

Use Perl regular expressions to specify the include and exclude patterns.

81.9.1 Resource Object

WebSphereMQUNIX Server.

81.9.2 Default Schedule

The default interval for this script is **Every 30 minutes**.

81.9.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event? (y/n)	Set to **y** to raise events. The default is y.
Collect data? (y/n)	Set to **y** to collect data for graphs and reports. If set to **y**, the script returns the number of lines containing matching strings. The default is n.
WebSphere MQ error log file (full path)	Enter the full path to the WebSphere MQ error log file. The default path is `/var/mqm/errors/AMQERR01.LOG` You can only specify one file name for any job instance. To monitor multiple logs or files, create separate Knowledge Script jobs.
Regular expression specifying the include filter	Type a regular expression, in Perl, to identify the pattern you want to look for in the text file being monitored. Strings matching the include filter pattern are returned. The default expression matches all strings.
Modifier for the regular expression include filter	Optional modifiers can be used to change the behavior of the regular expression. For example, specifying "i" for this parameter makes the include filter case-insensitive.
Regular expression specifying the exclude filter	Type a regular expression, in Perl, to identify the pattern you want to exclude from matching in the text file being monitored. Strings matching the include filter pattern are returned.

Description	How to Set It
Modifier for the regular expression exclude filter	Optional modifiers can be used to change the behavior of the regular expression. For example, specifying "i" for this parameter makes the exclude filter case-insensitive.
Threshold for matching lines	Enter the number of times to detect a match before raising an event. The default is 0, the first instance exceeds the threshold and raises an event.
Event severity level	Set the event severity level, from 1 to 40, to indicate the importance of the event. Adjust the severity based on which log or type of event you are monitoring. The default is 5.

81.9.4 Creating Filters with Regular Expressions

Some Knowledge Scripts enable you to use regular expressions to define include and exclude filters for pattern-matching against the text being evaluated. Depending on the Knowledge Script you are working with, you may be able to use regular expression include and exclude filters when you are setting job properties, or you may be able to maintain your search criteria independently of the Knowledge Script parameters in a separate filter file. You may also be able to use regular expression modifiers to further refine your filtering.

For example, if your **include filter** looks like this `replic.*` and you specify the modifier `i` to make the search case-insensitive, the regular expression contains the wildcard (`.`) and repeat (`*`) special characters, indicating you want to find strings that start with `replic` followed by any string of characters. Messages containing either `replication` or `replicated` are captured.

The format is the same for the exclude filter. For example, to find log entries that do not start with the string `success`, the exclude filter might look like this:

```
^success.*
```

If you are only searching for included strings, you can leave the exclude filter blank. If you want to retrieve all messages in the log in a given interval, you can specify `.*` for the include filter and leave the exclude filter blank.

81.9.5 Using Special Characters

The following special characters can be used in regular expressions:

Character	Description
.	Wildcard for any one character
*	Repeat zero or more occurrences
^	Beginning of the line
\$	End of the line
\	Escape the next meta-character
|	Alternate matches
[ ]	Any character in the class set. You can specify individual characters or ranges.

Character	Description
( )	Grouping characters. For example, you can specify (a|b|c) to indicate a match with a, or b, or c.
+	Quantifier indicating one or more occurrences
?	Quantifier indicating zero or one occurrence
{*n*}	Quantifier indicating exactly *n* occurrences
\w	A word character (alphanumeric plus _)
\s	A white-space character
\d	A digit character

81.9.6 Using Regular Expression Modifiers

In addition to the special characters you can use in creating the regular expression, there are a number of modifiers that can be used to modify how pattern-matching is handled. Valid modifiers include:

Modifier	Description
c	Complements the search list
g	Matches globally as many times as possible
i	Makes the search case-insensitive
m	Treats the string as multiple lines
o	Interpolates variables only once
s	Treats the regular expression string as a single long line
x	Allows for regular expression extensions

For additional information about writing regular expressions, see your Perl documentation or other regular expression resources.

82 WIN2000 Knowledge Scripts

The Windows Server (WIN2000) category provides Knowledge Scripts for monitoring Windows servers.

From the Knowledge Script view of Control Center, you can access more information about any NetIQ-supported Knowledge Script by selecting it and clicking **Help**. Or in the Operator Console, click any Knowledge Script in the Knowledge Script pane and press **F1**.

Knowledge Script	What It Does
ADDNSRegistrationEventLog	Scans the Event Log for Active Directory-related DNS registration problems.
DFSLinkDown	Monitors the up and down status of a DFS root, link, or replica.
DFSServiceDown	Monitors the up and down status of the DFS service.
DiskQuotaStatus	Monitors disk quota status for the specified logical drive.
DNSAXFRStat	Monitors changes to AXFR statistics for a DNS since the last interval.
DNSDatabaseNodeMemory	Monitors the total memory used by a DNS service for database nodes.
DNSDynaUpdateError	Monitors the number of dynamic update rejections and timeouts during the monitoring interval.
DNSDynaUpdateStat	Monitors the total number of dynamic updates queued by the DNS server.
DNSEventLog	Scans the Windows event log for DNS entries matching your selection criteria.
DNSRecursiveQuery	Monitors recursive queries for the DNS server and checks the number of recursive query errors or timeouts per second.
DNSSecureUpdate	Monitors secure updates for the DNS server and checks the percentage of attempted updates that failed.
DNSTotalQuery	Monitors total query activity for a DNS server and checks the number of queries received per second and the number of responses sent per second.
DNSWINSStat	Monitors the WINS activity for a DNS server.
DNSZoneTransfer	Monitors DNS zone transfer activity and zone transfer failures.
FrsBusy	Monitors the CPU utilization and various statistics of FRS.
FrsEventLog	Scans the Windows FRS log for file replication events.
FrsReplicaError	Monitors the various error statistics of the FRS, including errors in authentication, bindings, and packets sent.
FrsServiceDown	Monitors the up and down status of the FRS.
GroupPolicyAddRemove	Determines whether a Group Policy has been added to or removed from a computer.

Knowledge Script	What It Does
GroupPolicyCount	Counts the number of Group Policies for the target server.
GroupPolicyLinkSnapshot	Lists the links associated with a group policy object.
GroupPolicyRefresh	Refreshes the computer or user group policy on the target server on demand.
GroupPolicySnapshot	Lists all the group policies on the target server.
IASServiceDown	Monitors the up and down status of the Internet Authentication Service.
LSASSWatch	Checks whether the Kerberos Key Distribution Center service process, LSASS, is running or hung.
MSIPackagesChange	Monitors the programs and components installed or uninstalled using the Microsoft Windows Installer (MSI).
PrinterErrors	Monitors printers for problems with printing jobs.
PrinterEventLog	Scans the Windows System log for printer-related events.
PrinterQueue	Monitors the printer queue length.
PrinterUtil	Monitors the bytes per second being handled by the printer.
RemoteStorageEventLog	Scans the Windows Application log for Remote Storage-related events.
RemoteStorageServiceDown	Monitors the up and down status of Remote Storage services.
RSVPEventLog	Scans the Windows Application log for QoS/RSVP-related events.
RSVPServiceDown	Monitors the up and down status of the QoS/RSVP service.
SMTPEventLog	Scans the Windows System log for SMTP-related events.
SMTPQueues	Monitors the queue length for the SMTP queues.
SMTPServiceDown	Monitors the up and down status of the SMTP service.

82.1 ADDNSRegistrationEventLog

Use this Knowledge Script to scan the Event Log for Active Directory-related DNS registration problems. Each time this script runs, it checks the Event Log for entries matching your selection criteria and raises an event if matching entries are found.

82.1.1 Resource Object

DNS folder

82.1.2 Default Schedule

The default interval for this script is **Every 10 minutes**.

82.1.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Event?	Set to **y** to raise an event if log entries match your selection criteria. The default is y.
Collect data?	Set to **y** to collect data for charts and reports. If enabled, data collection returns information based on the other parameter values you enabled. The default is n.
Start with events in past N hours	Set this parameter to determine which events are searched for the *first* time the Knowledge Script is run. Subsequent searches begin where the last search finished. The following entries are valid: • Enter **-1** to search all current and previous System Log events during the first interval. • Enter **0** to search only for current events; previous events are not searched. • Enter the number of hours to go back in the System Log to scan for matching events. For example, enter 8 to scan the last 8 hours of the System Log for matching entries. The default is 0.
Monitor for events of type:	Set to **y** for each type of event you want to monitor: • Error • Warning • Information • Success Audit • Failure Audit If you enable data collection or events, and set any of these parameters to n, this script does not raise an event or collect data for that type of log entry. The default is y.

Parameter	How to Set It
Filter the [...] field for	To limit the types of entries that raise AppManager events and the type of data that is collected, enter a search string that filters the following fields in the Windows Event Log: • **Category**. Specify one or more text strings to look for in the Category field. Separate multiple strings with commas. • **User**. Specify a search string to look for events associated with a particular user, for example, `<domain name>\<user name>`. Separate multiple strings with commas. For example: `USA\Tom,USA\Chris,EUROPE\Alex`. • **Computer**. Specify computer names to look for. Separate multiple entries with commas. For example: SHASTA,MARS. • **Description**. Specify a detail description or keywords in the description. A string can contain spaces, underscores, and periods. Separate multiple entries with commas. For example: `no domain,critical error from the Active Directory`. The search string can contain criteria used to include entries, exclude entries, or both. Separate the include and exclude criteria with a colon (:). If you are specifying only include criteria, the colon is not necessary.
Max number of events per entry	Specify the maximum number of DNS Registration Event Log events that can be returned in each event report. For example, if this value is set to 30, and 67 Registration Event Log events are found, then three event reports are raised: two reports containing 30 events and one report containing seven events. The Message column on the Events tab displays the number of events in the event report, the type of log the events are from, and the event report batch number. The batch number is the sequential number of the event report. Batch numbers start at 1 for each Knowledge Script iteration. The default is 30.
Event severity	Set the event severity level, from 1 to 40, to indicate the importance of the an event in which log entries match your selection criteria. You can adjust the severity based on the types of events you are checking. The default severity level is 8 (red event indicator).

82.2 DFSLinkDown

Use this Knowledge Script to monitor Distributed File System (DFS) roots, links, and replicas. For each root replica and link replica, you can check whether the directory for the corresponding replica exists. This script raises an event if any root, root replica, link, or link replica is down.

By default, this script checks the DFS roots and links found during discovery. You can, however, set this script to discover DFS links dynamically each time it runs.

82.2.1 Resource Objects

DFS folder

DFS Root folder

DFS Link object

82.2.2 Default Schedule

The default interval for this script is **Every 10 minutes**.

82.2.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Event Notification	
Create event if root, link, or replica is down?	Set to **Yes** to raise an event when a DFS root, link, or replica is down. The default is Yes.
Severity - DFS volume down	Set the severity level, from 1 to 40, to indicate the importance of an event in which DFS volume is down. The default is 5 (red event indicator).
Severity - DFS path not found	Set the severity level, from 1 to 40, to indicate the importance of an event in which the DFS path cannot be found. The default is 22 (blue event indicator).
Severity - DFS root down	Set the severity level, from 1 to 40, to indicate the importance of an event in which the DFS root is down. The default is 5 (red event indicator).
Severity - DFS root replica down	Set the severity level, from 1 to 40, to indicate the importance of an event in which the DFS root replica is down. The default is 6 (red event indicator).
Severity - DFS link down	Set the severity level, from 1 to 40, to indicate the importance of an event in which the DFS link is down. The default is 7 (red event indicator).
Severity - DFS link replica down	Set the severity level, from 1 to 40, to indicate the importance of an event in which the DFS link replica is down. The default is 8 (red event indicator).
Severity - Job failure	Set the severity level, from 1 to 40, to indicate the importance of an event in which the DFSLinkDown job fails unexpectedly. The default is 5 (red event indicator).
Data Collection	

Parameter	How to Set It
Collect data?	Set to **Yes** to collect data for charts and reports. If enabled, data collection returns: • **100** – a root, link, or replica is up, or • **0** – a root, link, or replica is down. The default is unselected.
Monitoring	
Dynamically enumerate DFS root/links?	Set to **Yes** to dynamically enumerate DFS links at each monitoring interval. The default is unselected. **NOTE:** If you select Yes, run this script on the DFS folder object.
Check if the replica directory exists	Set to **Yes** to check for replica directories for each root or link found. The default is unselected. **NOTE:** If the AppManager agent services, NetIQ AppManager Client Resource Monitor (`NetIQmc.exe`) and NetIQ AppManager Client Communication Manager (`NetIQccm.exe`), are running under the Local System account or under a user account that does not have permission to read some directories, checking for replica directories may fail and cause this script to return an error.

82.3 DFSServiceDown

Use this Knowledge Script to monitor the up and down status of Distributed File System (DFS) roots, links, and replicas. You can set this script to automatically attempt to restart roots, links, and replicas when they are not running. This script raises an event when auto-start fails, succeeds, or when roots, links, or replicas are down but the *Auto-start service?* parameter is set to n.

82.3.1 Resource Objects

DFS Namespace Service object

DFS Replication Service object

82.3.2 Default Schedule

The default interval for this script is **Every 5 minutes**.

82.3.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Event?	Set to **y** to raise an event if auto-start fails, succeeds, or is disabled. The default is y.
Collect data?	Set to **y** to collect data for charts and reports. If enabled, data collection returns: • **100** – the Distributed File System service is up, or • **0** – the service is down. These values are used to report the percentage of time the service is up in any given period. The default is n.
Auto-start service?	Set to **y** to automatically restart the DFS service when it is down. The default is y.
Event severity when auto-start fails	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the service is down and AppManager cannot restart it. The default is 5 (red event indicator).
Event severity when auto-start succeeds	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the service was down and AppManager successfully restarted it. The default is 25 (blue event indicator).
Event severity when auto-start is set to n	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the service is down and the *Auto-start service?* parameter has been disabled. The default is 18 (yellow event indicator).
Severity for an unexpected KS error	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the DFSServiceDown job fails unexpectedly. The default is 35 (magenta event indicator).

82.4 DiskQuotaStatus

Use this Knowledge Script to monitor disk quota status. You can set disk quotas to limit the amount of file server disk space for each user. And you can determine how much disk space can be used before a warning is generated. This value is called the warning level.

For example, if the quota limit is set to 10 MB and the warning level is set to 8 MB, a warning message is generated when a user consumes 8 or more megabytes on the file server. When the user reaches the 10 MB quota limit, the user may or may not be able to save any more files, depending on how disk quotas are configured.

This script raises an event if the specified number or percentage of users reaches the warning level or quota limit.

82.4.1 Resource Objects

Disk Quota settings

82.4.2 Default Schedule

The default interval for this script is **Every hour**.

82.4.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Event?	Set to **y** to raise an event when a threshold is exceeded. The default is y.
Collect data—number of users over quota limit?	Set to **y** to collect data for charts and reports. If enabled, data collection returns the number of users over the quota limit. The default is n.
Collect data—number of users over warning level?	Set to **y** to collect data for charts and reports. If enabled, data collection returns the number of users over the warning level. The default is n.
Collect data—number of users below warning level?	Set to **y** to collect data for charts and reports. If enabled, data collection returns the number of users under the warning level. The default is n.
Collect data—percentage of users over quota limit?	Set to **y** to collect data for charts and reports. If enabled, data collection returns the percentage of users over the quota limit. The default is n.
Collect data—percentage of users over warning level?	Set to **y** to collect data for charts and reports. If enabled, data collection returns the percentage of users over the warning level. The default is n.
Collect data—percentage of users below warning level?	Set to **y t**o collect data for charts and reports. If enabled, data collection returns the percentage of users below the warning level. The default is n.
Collect data—disk space used for each user? (WARNING—heavy load)	Set to **y** to collect data for charts and reports. If enabled, data collection returns the amount of space being used by each user. The default is n. **NOTE:** Large amounts of CPU resources are required for this parameter to return results.

Parameter	How to Set It
Number of users over limit	Specify the maximum number of users who can be over the quota limit before an event is raised. The default is 1 user.
Number of users over warning level	Specify the maximum number of users who can be over the warning level before an event is raised. The default is 5 users.
Percentage of users over quota limit	Specify the maximum percentage of users who can be over the quota limit before an event is raised. The default is 10%.
Percentage of users over warning level	Specify the maximum percentage of users who can be over the warning level before an event is raised. The default is 20%.
Event severity - number of users over quota limit	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of users exceeded the quota threshold. The default is 8 (red event indicator).
Event severity - number of users over warning level	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of users exceeds the warning threshold. The default is 15 (yellow event indicator).
Event severity - percentage of users over quota limit	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the percentage of users exceeds the quota threshold. The default is 8 (red event indicator).
Event severity - percentage of users over warning level	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the percentage of users exceeds the warning threshold. The default is 15 (yellow event indicator).
Event severity - API error	Set the event severity level, from 1 to 40, to indicate the importance of an event in which network system errors occur. These errors can be hardware, software, or network related. The default is 7 (red event indicator).

82.5 DNSAXFRStat

Use this Knowledge Script to monitor the following AXFR (*zone transfer*, a database replication mechanism) statistics for Master and Secondary Domain Name System (DNS) servers:

- AXFR Request Received (Master)
- AXFR Success Sent (Master)
- AXFR Request Sent (Secondary)
- AXFR Response Received (Secondary)
- AXFR Success Received (Secondary)

This script monitors changes to these statistics since the last interval (delta value), and raises an event if a monitored value exceeds the threshold you set. If you collect data with this script, the AXFR statistics are returned as separate datastreams.

82.5.1 Resource Object

DNS folder

82.5.2 Default Schedule

The default interval for this script is **Every 30 minutes**.

82.5.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Event?	Set to **y** to raise an event if the number of transfer requests exceeds the threshold. The default is y.
Collect data?	Set to **y** to collect data for charts and reports. If enabled, data collection returns information about the transfer requests sent and received. The default is n.
Transfer requests	Specify the maximum number of transfer requests allowed before an event is raised. The default is 100.
Event severity	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of transfer requests exceeds the threshold. The default is 8 (red event indicator).

82.6 DNSDatabaseNodeMemory

Use this Knowledge Script to monitor the total memory used by the Domain Name Service (DNS) service for database nodes. This script raises an event if the memory used by DNS database nodes (in KB) exceeds the threshold you set.

82.6.1 Resource Object

DNS folder

82.6.2 Default Schedule

The default interval for this script is **Every 10 minutes**.

82.6.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Event?	Set to **y** to raise an event if the amount of memory used by the DNS service exceeds the threshold. The default is y.
Collect data?	Set to **y** to collect data for charts and reports. If enabled, data collection returns the size of database node memory. The default is n.
Memory used (KB)	Specify the maximum amount of memory that can be used by DNS database nodes before an event is raised. The default is 800 KB.
Event severity	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the amount of memory used by the DNS service exceeds the threshold. The default is 8 (red event indicator).

82.7 DNSDynaUpdateError

Use this Knowledge Script to monitor the number of Domain Name Service (DNS) dynamic update errors. This script checks for two types of errors:

- Dynamic updates rejected by the DNS server
- Dynamic update timeouts of the DNS server

This script raises an event if the number of dynamic update errors in the interval exceeds the threshold you set.

The dynamic update mechanism allows clients and servers to register DNS domain names and IP address mappings to a DNS server.

82.7.1 Resource Object

DNS folder

82.7.2 Default Schedule

The default interval for this script is **Every 10 minutes**.

82.7.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Event?	Set to **y** to raise an event if the number of dynamic update errors exceeds the threshold. The default is y.
Collect data?	Set to **y** to collect data for charts and reports. If enabled, data collection returns the number of dynamic updates rejected and the number of dynamic update timeouts in the interval. The default is n.
Threshold for dynamic update errors	Specify the maximum number of dynamic update errors that can occur in an interval before an event is raised. The default is 2.
Event severity	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of dynamic update errors exceeds the threshold. The default is 8 (red event indicator).

82.8 DNSDynaUpdateStat

Use this Knowledge Script to monitor DNS server dynamic update activity. This script raises an event if the dynamic update queue length exceeds the threshold you set. A long queue usually indicates that the DNS server is overloaded and cannot process the update in a timely manner.

The dynamic update mechanism allows clients and servers to register DNS domain names and IP address mappings to a DNS server.

82.8.1 Resource Object

DNS folder

82.8.2 Default Schedule

The default interval for this script is **Every 10 minutes**.

82.8.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Event?	Set to **y** to raise an event if the number of dynamic updates in the queue exceeds the threshold. The default is y.
Collect data?	Set to **y** to collect data for charts and reports. If enabled, data collection returns the queue length for dynamic updates. To further control the data returned, specify the data collection mode to use. By default, data is not collected.
Data collection mode to use	Specify the type of data you want to collect. The following entries are valid: • **1** - to generate one datastream that records the update queue length. The data detail message describes the number updates received and written per second. • **2** - to generate one datastream that records the update queue length, but without the detail message. • **3** - to generate one datastream that tracks the update queue length, and three additional datastreams for the No Operation rate, the rate at which updates are being received, and the rate at which updates are being written to the database. The default is 1 (one datastream and detail message).
Dynamic update queue length	Specify the maximum number of dynamic updates that can be in the queue in an interval before an event is raised. The default is 5 updates.
Event severity	Set the event severity level, from 1 to 40, to indicate the importance of an event if the number of dynamic updates in the queue exceeds the threshold. The default is 8 (red event indicator).

82.9 DNSEventLog

Use this Knowledge Script to periodically scan the Domain Name Service (DNS) Server log for DNS events matching the criteria you specify.

In the first interval, the value you specify for the *Start with events in past N hours* parameter determines how far back in the log to check for matching entries. As the script continues to run at subsequent intervals, it checks for any new entries created since the last time the log was checked.

You can further restrict the types of log entries that generate an event in two ways:

- Use the *Monitor for events of type [...]* parameters to search only certain types of events, such as Warning events.
- Use the *Filter the [...] field for* parameters to search only for specific information, such as events associated with a specific user or computer name.

Each time this script runs, it checks the DNS Server log for entries matching your selection criteria and raises an event if matching entries are found. The event detail message returns the text of the log entries found. When this Knowledge Script is set to collect data, it returns the number of log entries found, and the data point detail message returns the text of the log entries.

82.9.1 Resource Object

DNS folder

82.9.2 Default Schedule

The default interval for this script is **Every 10 minutes**.

82.9.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Event?	Set to **y** to raise an event if log entries match your search criteria. The default is y.
Collect data?	Set to **y** to collect data for charts and reports. If enabled, data collection returns the number of new event log entries. The graph data detail message contains the text of the log entries. The default is n.
Start with events in past N hours	Set this parameter to determine which events are searched for the *first* time the script is run. Subsequent searches begin where the last search finished. The following entries are valid: • Enter **-1** to search all current and previous DNS Log events during the first interval. • Enter **0** to search only for current events; previous events are not searched. • Enter the number of hours to go back in the DNS Log to scan for matching events. For example, enter 8 to scan the last 8 hours of the DNS Log for matching entries. The default is 0.

Parameter	How to Set It
Monitor for events of type:	Set to **y** for each type of event you want to monitor: • Error • Warning • Information • Success Audit • Failure Audit If you enable data collection or events, and set any of these parameters to n, this script does not raise an event or collect data for that type of log entry. The default is y.
Filter the [...] field for	To limit the types of entries that raise events and the type of data that is collected, enter a search string that filters the following fields in the event log: • **Source**. Specify one or more text strings to look for in the Source field. Separate multiple strings with commas. For example: `DNS Server,general`. • **Category**. Specify one or more text strings to look for in the Category field. Separate multiple strings with commas. • **Event ID**. Specify a single event ID or a range of event IDs. Separate multiple entries by commas. For example: `414,1028-1400,4015`. • **User**. Specify a search string to look for events associated with a particular user, for example, `<domain name>\<user name>`. Separate multiple strings with commas. For example: `USA\Tom,USA\Chris,EUROPE\Alex`. • **Computer**. Specify a single or multiple computer names to look for. Separate multiple entries by commas. For example: `SHASTA,MARS`. • **Event Description**. Specify a detail description or keywords in the description. The string can contain spaces, underscores, and periods. Separate multiple entries with commas. For example: `no domain,critical error from the Active Directory` The search string can contain criteria used to include entries, exclude entries, or both. Separate the include and exclude criteria with a colon (:).
Maximum number of entries per event message	Specify the maximum number of entries to be recorded in each event's detail message. If, during any interval when it scans the log, this script finds more entries in the log than can be put into a single event message, it raises multiple events to return all the log entries. The default is 30 entries.
Event severity	Set the event severity level, from 1 to 40, to indicate the importance of an event in which log entries match your search criteria. You can adjust the severity level based on the types of events you are checking. The default is 8 (red event indicator).

82.10 DNSRecursiveQuery

Use this Knowledge Script to monitor Domain Name Service (DNS) server recursive query activity. This script checks the number of recursive query errors or timeouts per second, and raises an event if the number of recursive query error or timeouts per second exceeds the rate threshold you set.

82.10.1 Resource Object

DNS folder

82.10.2 Default Schedule

The default interval for this script is **Every 10 minutes**.

82.10.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Event?	Set to **y** to raise an event if the number of recursive query errors or timeouts exceeds the threshold. The default is y.
Collect data?	Set to **y** to collect data for charts and reports. If enabled, data collection returns the number of recursive queries, failures, and timeouts per second. The default is n.
Recursive query errors/timeouts	Specify the maximum number of recursive query errors or timeouts per second that can occur before an event is raised. The default is 2.
Event severity	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of recursive query errors or timeouts exceeds the threshold. The default is 8 (red event indicator).

82.11 DNSSecureUpdate

Use this Knowledge Script to monitor secure updates for the Domain Name Service (DNS) server, and check the percentage of update attempts that failed. This script raises an event if the percentage of secure update failures exceeds the threshold you set.

82.11.1 Resource Object

DNS folder

82.11.2 Default Schedule

The default interval for this script is **Every 10 minutes**.

82.11.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Event?	Set to **y** to raise an event in which the percentage of secure updates exceeds the threshold. The default is y.
Collect data?	Set to **y** to collect data for charts and reports. If enabled, returns the following information in separate datastreams: • Secure update failure rate • Secure update failure number • Secure update total number • Secure update received per second The default is n.
Secure update failures	Specify the maximum percentage of secure updates that are allowed to fail before raising an event. The default is 2%.
Event severity	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the percentage of secure updates exceeds the threshold. The default is 8 (red event indicator).

82.12 DNSTotalQuery

Use this Knowledge Script to monitor total query activity for a Domain Name Server (DNS) server. This script checks the number of queries received per second and the number of responses sent per second, and raises an event if the query-received rate or the response-sent rate exceeds the threshold you set.

82.12.1 Resource Object

DNS folder

82.12.2 Default Schedule

The default interval for this script is **Every 30 minutes**.

82.12.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Event?	Set to **y** to raise an event if the number of query transactions exceeds the threshold. The default is y.
Collect data?	Set to **y** to collect data for charts and reports. If enabled, data collection returns the total number of queries received per second and the total number of responses sent per second. The default is n.
Queries received/sent per second	Specify the maximum number of queries that can be received or responses that can be sent per second before an event is raised. The default is 10.
Event severity	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of query transactions exceeds the threshold. The default is 15 (yellow event indicator).

82.13 DNSWINSStat

Use this Knowledge Script to monitor the Windows Internet Name Service (WINS) activity for a Domain Name Service (DNS) server. This script checks the number of lookup requests received per second and the number of responses sent per second. This script raises an event if the lookup-received rate, reverse lookup-received rate, response-sent rate, or reverse response-sent rate exceeds the threshold you set.

82.13.1 Resource Object

DNS folder

82.13.2 Default Schedule

The default interval for this script is **Every 30 minutes**.

82.13.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Event?	Set to **y** to raise an event if the sent or received rates exceed the threshold. The default is y.
Collect data?	Set to **y** to collect data for charts and reports. If enabled, data collection returns four datastreams: • WINS lookups received per second • WINS responses sent per second • WINS reverse lookups received per second • WINS reverse responses sent per second The default is n.
Lookups received/sent per second	Specify the maximum number of lookups that can be received or responses that can be sent per second before an event is raised. The default is 20 per second.
Event severity	Set the event severity level, from 1 to 40, to indicate the importance of an event in which a threshold is exceeded. The default is 15 (yellow event indicator).

82.14 DNSZoneTransfer

Use this Knowledge Script to monitor Domain Name Service (DNS) zone transfer activity. You can set a threshold for the number of zone transfer failures in an interval and a threshold for the percentage of zone transfers attempted that fail in an interval. This script raises an event if either the number or the percentage of zone transfer failures exceeds the threshold.

82.14.1 Resource Object

DNS folder

82.14.2 Default Schedule

The default interval for this script is **Every 30 minutes**.

82.14.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Event?	Set to **y** to raise an event if the number or percentage of zone transfer failures exceeds the threshold. The default is y.
Collect data?	Set to **y** to collect data for charts and reports. If enabled, data collection returns in five separate datastreams: • Number of zone transfer failures • Number of successful zone transfers • Number of requests received • Number of SOA (Start of Authority) requests sent • Percentage of zone transfers that failed The default is n.
Zone transfer failures	Specify the maximum number of zone transfer failures that can occur before an event is raised. The default is 5.
Percentage of zone transfer failures	Specify the maximum percentage of zone transfer that can fail before an event is raised. The default is 20%.
Event severity	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number or percentage of zone transfer failures exceeds the threshold. The default severity level is 8 (red event indicator).

82.15 FrsBusy

Use this Knowledge Script to monitor the CPU utilization and various statistics of the File Replication Service (FRS). This script raises an event if a threshold is exceeded.

82.15.1 Resource Object

File Replication Service folder

82.15.2 Default Schedule

The default interval for this script is **Every 10 minutes**.

82.15.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Event?	Set to **y** to raise an event if a threshold is exceeded. The default is y.
Collect data?	Set to **y** to collect data for charts and reports. If enabled, returns data based on the threshold values you set. The default is n.
CPU utilization of the File Replication Service	Specify the maximum percentage of CPU resources the FRS can utilize before an event is raised. The default is 5%.
Number of change orders received	Specify the maximum number of change orders that can be received before an event is raised. The default is 5.
Number of change orders sent	Specify the maximum number of change orders that can be sent before an event is raised. The default is 5.
Number of files installed	Specify the maximum number of replicated files that can be installed locally before an event is raised. The default is 2.
KB of free staging space	Specify the minimum amount of free space in the staging directory that must be available to prevent an event from being raised. The default is 10 KB.
Percentage of free staging space	Specify the minimum percentage of free space in the staging directory that must be available to prevent an event from being raised. The default is 10%.
Number of packets received	Specify the maximum number of packets that can be received before an event is raised. The default is 10.
Number of packets sent	Specify the maximum number of packets that can be sent before an event is raised. The default is 10.
Number of USN records accepted	Specify the maximum number of USN records that can be accepted for replication before an event is raised. The default is 5.
Event severity	Set the event severity level, from 1 to 40, to indicate the importance of an event in which a monitored value exceeds or falls below the threshold. The default is 8 (red event indicator).
Severity for unexpected KS error	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the FrsBusy job fails unexpectedly. The default is 35 (magenta event indicator).

82.16 FrsEventLog

Use this Knowledge Script to periodically scan the Windows File Replication Service (FRS) log for file replication events matching the criteria you specify.

Each time this script runs, it checks the FRS log for entries matching the criteria you specify and raises an event if matching entries are found. The event detail message returns the text of the log entries found. When this script is set to collect data, it returns the number of log entries found, and the data point detail message returns the text of the log entries.

In the first interval, the value you specify for the *Start with events in past N hours* parameter determines how far back in the log to check for matching entries. As the script continues to run at subsequent intervals, it checks for any new entries created since the last time the log was checked.

You can further restrict the types of log entries that generate an event in two ways:

- Use the *Monitor for events of type [...]* parameters to search only certain types of events, such as Warning events.
- Use the *Filter the [...] field for* parameters to search only for specific information, such as events associated with a specific user or computer name.

82.16.1 Resource Object

File Replication Service folder

82.16.2 Default Schedule

The default interval for this script is **Every 10 minutes**.

82.16.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Event?	Set to **y** to raise an event if FRS log entries match your search criteria. The default is y.
Collect data?	Set to **y** to collect data for charts and reports. If enabled, data collection returns the number of new FRS log entries. The default is n.
Start with events in past N hours	Set this parameter to determine which events are searched for the *first* time this script is run. Subsequent searches begin where the last search finished. The following entries are valid: • Enter **-1** to search all current and previous File Replication Log events during the first interval. • Enter **0** to search only for current events; previous events are not searched. • Enter the number of hours to go back in the FRS Log to scan for matching events. For example, enter 8 to scan the last 8 hours of the File Replication Log for matching entries. The default is 0.

Parameter	How to Set It
Monitor for events of type:	Set to **y** for each type of event you want to monitor: • Error • Warning • Information • Success Audit • Failure Audit If you enable data collection or events, and set any of these parameters to n, this script does not raise an event or collect data for that type of log entry. The default is y.
Filter the [...] field for	To limit the types of entries that raise events and the type of data that is collected, enter a search string that filters the following fields in the event log: • **Source**. Specify text strings to look for in the Source field. Separate multiple strings with commas. • **Category**. Specify text strings to look for in the Category field. Separate multiple strings with commas. • **Event ID**. Specify a single event ID or a range of event IDs. Separate multiple entries with commas. For example: 414,1028-1400,4015. • **User**. Specify a search string to look for events associated with a particular use, for example, `<domain name>\<user name>`. Separate multiple strings with commas. For example: `USA\Tom,USA\Chris,EUROPE\Alex`. • **Computer**. Specify computer names to look for. Separate multiple entries by commas. For example: SHASTA,MARS. • **Event Description**. Specify a detail description or keywords in the description. The string can contain spaces, underscores, and periods. Separate multiple entries with commas. For example: `no domain,critical error from the Active Directory`. The search string can contain criteria used to include entries, exclude entries, or both. Separate the include and exclude criteria with a colon (:). If you are specifying only include criteria, the colon is not necessary.
Maximum number of entries per event message	Specify the maximum number of entries to be recorded in each event's detail message. If, during any interval when it scans the log, this script finds more entries in the log than can be put into a single event message, it raises multiple events to return all the log entries. The default is 30 entries.
Event severity	Set the event severity level, from 1 to 40, to indicate the importance of an event in which FRS log entries match your search criteria. You can adjust the severity level based on the types of events you are checking for. The default is 8 (red event indicator).

82.17 FrsReplicaError

Use this Knowledge Script to monitor the various error statistics of the File Replication Service (FRS), including errors in authentication, bindings, and packets sent. This script monitors two objects within the FRS:

- The `FileRelicaConn` object monitors performance statistics for the `Replicaconn` object, which defines replica connections for the DFS roots.
- The `FileReplicaSet` object monitors performance statistics for the `Replicaset` object, which defines a replica set.

This script raises an event if a monitored value exceeds the threshold you set.

82.17.1 Resource Object

File Replication Service folder

82.17.2 Default Schedule

The default interval for this script is **Every 30 minutes**.

82.17.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Event?	Set to **y** to raise an event if a threshold is exceeded. The default is y.
Collect data?	Set to **y** to collect data for charts and reports. If enabled, data collection returns data based on the thresholds you set. The default is n.
The number of FileReplicaConn...	Specify the maximum number of errors that can be encountered by the `FileReplicaConn` object before an event is raised in each of these categories: ...authentications in error ...bindings in error ...packets sent in error
The number of FileReplicaSet...	Specify the maximum number of errors that can be encountered by the `FileReplicaSet` object before an event is raised in each of these categories: ...authentications in error ...bindings in error ...DS bindings in error ...DS objects in error ...DS searches in error ...files installed with errors ...packets received in error ...packets sent in error ...staging files generated with errors
Event severity	Set the event severity level, from 1 to 40, to indicate the importance of an event in which a threshold is exceeded. The default severity level is 8 (red event indicator).

82.18 FrsServiceDown

Use this Knowledge Script to monitor the up and down status of the File Replication Service (FRS). You can set this script to automatically attempt to restart the service when it is not running. This script raises an event when auto-start fails or succeeds, or when the service is down but the *Auto-start service?* parameter is set to n.

82.18.1 Resource Object

File Replication Service object

82.18.2 Default Schedule

The default interval for this script is **Every 5 minutes**.

82.18.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Event?	Set to **y** to raise an event when auto-start fails, succeeds, or when the service is down but the *Auto-start service?* parameter is disabled. The default is y.
Collect data?	Set to **y** to collect data for charts and reports. If enabled, data collection returns: • **100** – the FRS is up • **0** – the FRS is down These values are used to report the percentage of time the service is up in any given period. The default is n.
Auto-start service?	Set to **y** to automatically restart FRS when it is down. The default is y.
Event severity when auto-start fails	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the service is down and AppManager cannot restart it. The default is 5 (red event indicator).
Event severity when auto-start succeeds	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the service was down and AppManager successfully restarted it. The default is 25 (blue event indicator).
Event severity when auto-start is set to n	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the service is down and the *Auto-start service?* parameter has been disabled. The default is 18 (yellow event indicator).
Severity for an unexpected KS error	Set the level between 1 and 40, to indicate the importance of an event in which the FrsServiceDown job fails unexpectedly. The default is 35 (magenta event indicator).

82.19 GroupPolicyAddRemove

Use this Knowledge Script to check whether a Group Policy has been added to or removed from a target computer. This script raises an event if a Group Policy is added or removed during the monitoring interval.

82.19.1 Resource Object

Group Policy top-level folder

82.19.2 Default Schedule

The default interval for this script is **Every 30 minutes**.

82.19.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Event?	Set to **y** to raise an event if a Group Policy is added or removed during the monitoring interval. The default is y.
Collect data?	Set to **y** to collect data for charts and reports. If enabled, data collection returns: • **100** – there were no Group Policy changes, or • **0** – a Group Policy was added or removed during the interval. The default is n.
Event severity when a Group Policy is added	Set the event severity level, from 1 to 40, to indicate the importance of an event in which a Group Policy was added during the monitoring period. The default is 5 (red event indicator).
Event severity when a Group Policy is removed	Set the event severity level, from 1 to 40, to indicate the importance of an event in which a Group Policy was removed during the monitoring period. The default is 5 (red event indicator).

82.20 GroupPolicyCount

Use this Knowledge Script to count the number of Group Policies associated with the target server in Active Directory. This script raises an event if the number of Group Policies associated with the server exceeds the threshold you set.

82.20.1 Resource Object

Group Policy top-level folder

82.20.2 Default Schedule

The default interval for this script is **Every 30 minutes**.

82.20.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Event?	Set to **y** to raise an event if the number of Group Policies exceeds the threshold you set. The default is y.
Collect data?	Set to **y** to collect data for charts and reports. If enabled, data collection returns the number of Group Policies found. The default is n.
Group Policies	Specify the maximum number of Group Policies that can be associated with a computer in Active Directory before an event is raised. The default is 5 Group Policies.
Event severity	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of Group Policies exceeds the threshold. The default is 5 (blue event indicator).

82.21 GroupPolicyLinkSnapshot

Use this Knowledge Script to list the links associated with one or multiple Group Policy objects. This script raises an event if Group Policy links are found or not found.

82.21.1 Resource Object

Windows Server 2003 Group Policy object

82.21.2 Default Schedule

The default interval for this script is **Run once**.

82.21.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Event?	Set to **y** to raise an event if Group Policy links are found or not found. The default is y.
Collect data?	Set to **y** to collect data for charts and reports. If enabled, data collection returns the number of Group Policy links found. The default is n.
Event severity when Group Policy link is found	Set the event severity level, from 1 to 40, to indicate the importance of an event in which Group Policy links have been detected and returned in the event detail message. The default is 25 (blue event indicator).
Event severity when Group Policy link is not found	Set the event severity level, from 1 to 40, to indicate the importance of an event in which no Group Policy links have been detected. The default is 5 (red event indicator).

82.22 GroupPolicyRefresh

Use this Knowledge Script to refresh the computer Group Policy or the user Group Policy without restarting the computer or re-entering login information. This script refreshes the computer or user policy for all the Group Policies associated with the target computer.

82.22.1 Resource Object

Group Policy folder

82.22.2 Default Schedule

The default interval for this script is **Every 30 minutes**.

82.22.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Event for a successful refresh policy?	Set to **y** to raise an event when the refresh succeeds. This script always raises an event when the refresh fails. The default is y.
Refresh computer group policy?	Set to **y** to refresh the computer Group Policy. The default is y.
Refresh user group policy?	Set to **y** to refresh the user Group Policy. The default is n.
Event severity when a refresh is successful	Set the event severity level, from 1 to 40, to indicate the importance of an event in which a refresh of the computer or user Group Policy succeeds. The default is 25 (blue event indicator).
Event severity when a refresh fails	Set the event severity level, from 1 to 40, to indicate the importance of an event in which a refresh of the computer or user Group Policy fails. The default is 25 (blue event indicator).

82.23 GroupPolicySnapshot

Use this Knowledge Script to list all the Group Policies on the target server in priority order. This script raises an event if Group Policies are found. If you enable data collection, the event detail message lists all the Group Policies sorted in the following priority order:

- Local Group Policies are listed first
- Default Domain Group Policy are listed second
- Default Domain Controller Group Policy are listed last

No event is raised if no Group Policies are found for the target computer.

82.23.1 Resource Object

Group Policy top-level folder

82.23.2 Default Schedule

The default interval for this script is **Run once**.

82.23.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Event?	Set to **y** to raise an event if Group Policies are found. The default is y.
Collect data?	Set to **y** to collect data for charts and reports. If enabled, data collection returns the number of Group Policies found. The default is n.
Event severity	Set the event severity level, from 1 to 40, to indicate the importance of an event in which Group Policies are found. The default is 25 (blue event indicator).

82.24 IASServiceDown

Use this Knowledge Script to monitor up and down status of the Internet Authentication Service (IAS). You can set this script to automatically attempt a service restart when it is not running. This script raises an event when auto-start fails, succeeds, or is disabled.

82.24.1 Resource Object

Internet Authentication Service object

82.24.2 Default Schedule

The default interval for this script is **Every 5 minutes**.

82.24.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Event?	Set to **y** to raise an event if auto-starts fails, succeeds, or is disabled. The default is y.
Collect data?	Set to **y** to collect data for charts and reports. If enabled, data collection returns: • **100** – the Internet Authentication Service is up, or • **0** – the service is down. These values are used to report the percentage of time the service is up in any given period. The default is n.
Auto-start service?	Set to **y** to automatically restart IAS when it is down. The default is y.
Event severity when auto-start fails	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the service is down and AppManager cannot restart it. The default is 5 (red event indicator).
Event severity when auto-start succeeds	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the service was down and AppManager successfully restarted it. The default is 25 (blue event indicator).
Event severity when auto-start is set to n	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the service is down and the *Auto-start service?* parameter has been disabled. The default is 18 (yellow event indicator).
Severity for an unexpected KS error	Set the level between 1 and 40, to indicate the importance of an event in which the IASServiceDown job fails unexpectedly. The default is 35 (magenta event indicator).

82.25 LSASSWatch

Use this Knowledge Script to check whether the Kerberos Key Distribution Center service (specifically, the LSASS process) is running or hung. This script also monitors the amount of CPU time the LSASS process is using. You specify the threshold for CPU usage and the number of consecutive times the threshold can be exceeded before raising an event.

This script raises an event if the LSASS process is not running or if the process is using a large amount of CPU over a consecutive number of intervals (known as looping).

82.25.1 Resource Objects

Windows 2000 Server or later

82.25.2 Default Schedule

The default interval for this script is **Every 10 minutes**.

82.25.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Event?	Set to **y** to raise an event if CPU usage exceeds the threshold. The default is y.
Collect data?	Set to **y** to collect data for charts and reports. If enabled, data collection returns: • **100** – the process is running, or • **0** – the process is down. The default is n.
High CPU usage	Specify the maximum amount of CPU that the LSASS process can consume before an event is raised. The default is 90%.
Consecutive times LSASS has high CPU usage	Specify the consecutive number of intervals the CPU usage of the LSASS process can exceed the threshold before an event is raised. The default is 3 times.
Event severity - Process appears to be hung	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the LSASS process is hung, or looping. The default is 5 (yellow event indicator).
Event severity - Process is not running	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the LSASS process is not running. The default is 15 (yellow event indicator).

82.26 MSIPackagesChange

Use this Knowledge Script to monitor the programs or components installed or uninstalled using the Microsoft Windows Installer (MSI). This script tracks the changes recorded in the registry under `SOFTWARE\Microsoft\Windows\CurrentVersion\Uninstall` and reports the number of MSI packages that were installed, uninstalled, or updated during the monitoring period.

If you enable detailed data collection, the name, version, publication name, and installation date are returned for each MSI package.

82.26.1 Resource Objects

Windows 2000 Server or later

82.26.2 Default Schedule

The default interval for this script is **Daily**.

82.26.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Event?	Set to **y** to raise an event if an MSI package is installed, uninstalled, or updated. The default is y.
Collect data?	Set to **y** to collect data for charts and reports. If enabled, data collection returns the number of currently installed packages. The default is n.
Create data detail message with package information	Set to **y** to generate the data detail message including package name, version, publication name, and installation date. The default is n.
Event severity	Set the event severity level, from 1 to 40, to indicate the importance of an event in which an MSI package is installed, uninstalled, or updated. The default is 8 (red event indicator).

82.27 PrinterErrors

Use this Knowledge Script to monitor printer-related errors:

- Print job errors (such as, print jobs that are hung because of data transfer problems or paper jams)
- Printer not ready errors
- Printer out of paper errors

You can set a separate threshold for each type of printer error. This script raises an event if any error type exceeds the threshold you set.

NOTE: To run this script successfully, avoid using special characters such as, /, -, and # when defining the printer name on the monitored computers. Also, if you run the Discovery_NT Knowledge Script and then delete a local or network printer, run Discovery_NT again.

82.27.1 Resource Object

Printer object

82.27.2 Default Schedule

The default interval for this script is **Every 10 minutes**.

82.27.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Event?	Set to **y** to raise an event if a threshold is exceeded. The default is y.
Collect data?	Set to **y** to collect data for charts and reports. If enabled, data collection returns: • **100** – the process is running, or • **0** – the process is down. The default is n.
Threshold for the number of "Print job" errors	Specify the maximum number of print job errors that can occur in an interval before an event is raised. The default is 5 errors.
Threshold for the number of "Printer not ready" errors	Specify the maximum number of printer "not ready" errors that can occur in an interval before an event is raised. The default is 5 errors.
Threshold for the number of "Out of paper" errors	Specify the maximum number of "out of paper" errors that can occur in an interval before an event is raised. The default is 10 errors.
Event severity	Set the event severity level, from 1 to 40, to indicate the importance of an event in which a threshold is exceeded. The default is 8 (red event indicator).

82.28 PrinterEventLog

Use this Knowledge Script to periodically scan the Windows System log for printer-related events matching the criteria you specify.

Each time this script runs, it checks the System log for entries matching your selection criteria and raises an event if matching entries are found. The event detail message returns the text of the log entries found. When this script is set to collect data, it returns the number of log entries found, and the data point detail message returns the text of the log entries.

In the first interval, the value you specify for the *Start with events in past N hours* parameter determines how far back in the log to check for matching entries. As the script continues to run at subsequent intervals, it checks for any new entries created since the last time the log was checked.

You can further restrict the types of log entries that generate an event in two ways:

- Use the *Monitor for events of type [...]* parameters to search only certain types of events, such as Warning events.
- Use the *Filter the [...] field for* parameters to search only for specific information, such as events associated with a specific user or computer name.

NOTE: To run this script successfully, avoid using special characters such as /, -, and # when defining the printer name on the monitored computers. Also, if you run the Discovery_NT Knowledge Script and then delete a local or network printer, you must run Discovery_NT again.

82.28.1 Resource Object

Printer folder

82.28.2 Default Schedule

The default interval for this script is **Every 10 minutes**.

82.28.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Event?	Set to **y** to raise an event if log entries match your search criteria. The default is y.
Collect data?	Set to **y** to collect data for charts and reports. If enabled, data collection returns the number of new event log entries. The default is n.

Parameter	How to Set It
Start with events in past N hours	Set this parameter to determine which events are searched for the first time the script is run. Subsequent searches begin where the last search finished. The following entries are valid: • Enter -1 to search all current and previous System Log events during the first interval. • Enter 0 to search only for current events; previous events are not searched. • Enter the number of hours to go back in the System Log to scan for matching events. For example, enter 8 to scan the last 8 hours of the System Log for matching entries. The default is 0.
Monitor for events of type:	Set to **y** for each type of event you want to monitor: • Error • Warning • Information • Success Audit • Failure Audit If you enable data collection or events, and set any of these parameters to n, this script does not raise an event or collect data for that type of log entry. The default is y.
Filter the [...] field for	To limit the types of entries that raise events and the type of data that is collected, enter a search string that filters the following fields in the event log: • **Category**. Specify text strings to look for in the Category field. Separate multiple strings with commas. • **Event ID**. Specify a single event ID or a range of event IDs. Separate multiple entries by commas. For example: 414,1028-1400,4015. • **User**. Specify a search string to look for events associated with a particular user, for example, `<domain name>\<user name>`. Separate multiple strings with commas. For example: `USA\Tom,USA\Chris,EUROPE\Alex`. • **Computer**. Specify computer names to look for. Separate multiple entries by commas. For example: SHASTA,MARS. • **Event Description**. Specify a detail description or keywords in the description. The string can contain spaces, underscores, and periods. Separate multiple entries with commas. The search string can contain criteria used to include entries, exclude entries, or both. Separate the include and exclude criteria with a colon (:). If you are specifying only include criteria, the colon is not necessary.
Maximum number of entries per event message	Specify the maximum number of entries to be recorded in each event's detail message. If, during any interval when it scans the log, the script finds more entries in the log than can be put into a single event message, it raises multiple events to return all the log entries. Default is 30 entries.
Event severity	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the log contains entries that match your search criteria. You can adjust the severity based on the types of events you are checking. The default is 8 (red event indicator).

82.29 PrinterQueue

Use this Knowledge Script to monitor the printer queue length. This script raises an event if the printer queue length exceeds the threshold you set.

This script is not supported on 64-bit systems.

NOTE: To run this script successfully, avoid using special characters such as, /, -, and # when defining the printer name on the monitored computers. Also, if you run the Discovery_NT Knowledge Script and then delete a local or network printer, run Discovery_NT again.

82.29.1 Resource Object

Local or cluster printer object

82.29.2 Default Schedule

The default interval for this script is **Every 10 minutes**.

82.29.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Event?	Set to **y** to raise an event if the number of print jobs in the queue exceeds the threshold. The default is y.
Collect data?	Set to **y** to collect data for charts and reports. If enabled, data collection returns the current printer queue length. The default is n.
Threshold for printer queue length	Specify the maximum number of print jobs that can be in the printer queue before an event is raised. The default is 5 jobs.
Event severity	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of print jobs in the queue exceeds the threshold. The default is 8 (red event indicator).

82.30 PrinterUtil

Use this Knowledge Script to monitor printer utilization by tracking the number of bytes printed per second. This script raises an event if the number of bytes per second exceeds the threshold you set.

NOTE: To run this script successfully, avoid using special characters such as, /, -, and # when defining the printer name on the monitored computers. Also, if you run the Discovery_NT Knowledge Script and then delete a local or network printer, run Discovery_NT again.

82.30.1 Resource Object

Local or cluster printer object

82.30.2 Default Schedule

The default interval for this script is **Every 10 minutes**.

82.30.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Event?	Set to **y** to raise an event if the number of bytes printed per second exceeds the threshold. The default is y.
Collect data?	Set to **y** to collect data for charts and reports. If enabled, data collection returns the number of bytes printed per second. The default is n.
Threshold for bytes printed per second	Specify the maximum number of bytes that can be printed per second before an event is raised. The default is 2000 bytes.
Event severity	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of bytes printed per second exceeds the threshold. The default is 8 (red event indicator).

82.31 RemoteStorageEventLog

Use this Knowledge Script to periodically scan the Windows Application log for Remote Storage-related events matching the criteria you specify.

Each time this script runs, it checks the Application log for entries matching your selection criteria and raises an event if matching entries are found. The event detail message returns the text of the log entries found. When this script is set to collect data, it returns the number of log entries found, and the data point detail message returns the text of the log entries.

In the first interval, the value you specify for the *Start with events in past N hours* parameter determines how far back in the log to check for matching entries. As the script continues to run at subsequent intervals, it checks for any new entries created since the last time the log was checked.

You can further restrict the types of log entries that generate an event in two ways:

- Use the *Monitor for events of type [...]* parameters to search only certain types of events, such as Warning events.
- Use the *Filter the [...] field for* parameters to search only for specific information, such as events associated with a specific user or computer name.

82.31.1 Resource Object

Remote Storage folder

82.31.2 Default Schedule

The default interval for this script is **Every 10 minutes**.

82.31.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Event?	Set to **y** to raise an event if log entries match your search criteria. The default is y.
Collect data?	Set to **y** to collect data for charts and reports. If enabled, data collection returns the number of new event log entries. The default is n.
Start with events in past N hours	Set this parameter to determine which events are searched for the *first* time the script is run. Subsequent searches begin where the last search finished. The following entries are valid: • Enter -1 to search all current and previous Application Log events during the first interval. • Enter 0 to search only for current events; previous events are not searched. • Enter the number of hours to go back in the Application Log to scan for matching events. For example, enter 8 to scan the last 8 hours of the Application Log for matching entries. The default is 0.

Parameter	How to Set It
Monitor for events of type:	Set to **y** for each type of event you want to monitor: • Error • Warning • Information • Success Audit • Failure Audit If you enable data collection or events, and set any of these parameters to n, this script does not raise an event or collect data for that type of log entry. The default is y.
Filter the [...] field for	To limit the types of entries that raise events and the type of data that is collected, enter a search string that filters the following fields in the event log: • **Category**. Specify text strings to look for in the Category field. Separate multiple strings with commas. • **Event ID**. Specify a single event ID or a range of event IDs. Separate multiple entries by commas. For example: 414,1028-1400,4015. • **User**. Specify a search string to look for events associated with a particular user, for example, `<domain name>\<user name>`. Separate multiple strings with commas. For example: `USA\Tom,USA\Chris,EUROPE\Alex`. • **Computer**. Specify a single or multiple computer names to look for. Separate multiple entries by commas. For example: SHASTA,MARS. • **Event Description**. Specify a detail description or keywords in the description. The string can contain spaces, underscores, and periods. Separate multiple entries with commas. The search string can contain criteria used to include entries, exclude entries, or both. Separate the include and exclude criteria with a colon (:). If you are specifying only include criteria, the colon is not necessary.
Maximum number of entries per event message	Specify the maximum number of entries to be recorded in each event's detail message. If, during any interval when it scans the log, this script finds more entries in the log than can be put into a single event message, it raises multiple events to return all the log entries. The default is 30 entries.
Event severity	Set the event severity level, from 1 to 40, to indicate the importance of an event in which log entries match your search criteria. You can adjust the severity based on the types of events you are checking. The default is 8 (red event indicator).

82.32 RemoteStorageServiceDown

Use this Knowledge Script to monitor the up and down status of the Remote Storage Service. You can set this script to automatically attempt to restart the service when it is not running. This script raises an event when auto-start fails, succeeds, or is disabled.

82.32.1 Resource Object

Remote Storage folder

82.32.2 Default Schedule

The default interval for this script is **Every 5 minutes**.

82.32.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Event?	Set to **y** to raise an event if auto-start fails, succeeds, or is disabled. The default is y.
Collect data?	Set to **y** to collect data for charts and reports. If enabled, data collection returns: • **100** – the Remote Storage services are up, or • **0** – any service is down. These values are used to report the percentage of time the service is up in any given period. The default is n.
Auto-start service?	Set to **y** to automatically restart any Remote Storage service when it is down. The default is y.
Severity when auto-start fails	Set the event severity level, from 1 to 40, to indicate the importance of an event in which service is down and AppManager cannot restart it. The default is 5 (red event indicator).
Severity when auto-start succeeds	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the service was down and AppManager successfully restarted it. The default is 25 (blue event indicator).
Severity when auto-start is set to n	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the service is down and the *Auto-start service?* parameter has been disabled. The default is 18 (yellow event indicator).
Severity for an unexpected KS error	Set the level between 1 and 40, to indicate the importance of an event in which the RemoteStorageServiceDown job fails unexpectedly. The default is 35 (magenta event indicator).

82.33 RSVPEventLog

Use this Knowledge Script to periodically scan the Windows Application log for QoS/RSVP-related events matching the criteria you specify.

Each time this script runs, it checks the Application log for entries matching your selection criteria and raises an event if matching entries are found. The event detail message returns the text of the log entries found. When data collection is enabled, the job returns the number of log entries found, and the data point detail message returns the text of the log entries.

In the first interval, the value you specify for the *Start with events in past N hours* parameter determines how far back in the log to check for matching entries. As the script continues to run at subsequent intervals, it checks for any new entries created since the last time the log was checked.

You can further restrict the types of log entries that generate an event in two ways:

- Use the *Monitor for events of type [...]* parameters to search only certain types of events, such as Warning events.
- Use the *Filter the [...] field for* parameters to search only for specific information, such as events associated with a specific user or computer name.

82.33.1 Resource Object

QoS folder

82.33.2 Default Schedule

The default interval for this script is **Every 10 minutes**.

82.33.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Event?	Set to **y** to raise an event if log entries match your search criteria. The default is y.
Collect data?	Set to **y** to collect data for charts and reports. If enabled, data collection returns the number of new event log entries. The graph data detail message returns the text of the log entries. The default is n.
Start with events in past N hours	Set this parameter to determine which events are searched for the *first* time the Knowledge Script is run. Subsequent searches begin where the last search finished. The following entries are valid: • Enter -1 to search all current and previous Application Log events during the first interval. • Enter 0 to search only for current events; previous events are not searched. • Enter the number of hours to go back in the Application Log to scan for matching events. For example, enter 8 to scan the last 8 hours of the Application Log for matching entries. The default is 0.

Parameter	How to Set It
Monitor for events of type:	Set to **y** for each type of event you want to monitor: • Error • Warning • Information • Success Audit • Failure Audit If you enable data collection or events, and set any of these parameters to n, this script does not raise an event or collect data for that type of log entry. The default is y.
Filter the [...] field for	To limit the types of entries that raise events and the type of data that is collected, enter a search string that filters the following fields in the event log: • **Category**. Specify text strings to look for in the Category field. Separate multiple strings with commas. • **Event ID**. Specify a single event ID or a range of event IDs. Separate multiple entries by commas. For example: 414,1028-1400,4015. • **User**. Specify a search string to look for events associated with a particular user, for example, `<domain name>\<user name>`. Separate multiple strings with commas. For example: `USA\Tom,USA\Chris,EUROPE\Alex`. • **Computer**. Specify computer names to look for. Separate multiple entries by commas. For example: SHASTA,MARS. • **Event Description**. Specify a detail description or keywords in the description. The string can contain spaces, underscores, and periods. Separate multiple entries with commas. The search string can contain criteria used to include entries, exclude entries, or both. Separate the include and exclude criteria with a colon (:). If you are specifying only include criteria, the colon is not necessary.
Maximum number of entries per event message	Specify the maximum number of entries to be recorded in each event's detail message. If, during any interval when it scans the log, the script finds more entries in the log than can be put into a single event message, it raises multiple events to return all the log entries. The default is 30 entries.
Event severity	Set the event severity level, from 1 to 40, to indicate the importance of an event in which log entries match your search criteria. You can adjust the severity based on the types of events you are checking. The default is 8 (red event indicator).

82.34 RSVPServiceDown

Use this Knowledge Script to monitor the Windows QoS/RSVP service. You can set this script to automatically attempt to restart the service when it is not running. This script raises an event if the service is not running, if the attempt to restart it fails, or if the service is down and the *Auto-start service?* parameter is set to n.

82.34.1 Resource Object

QoS folder

82.34.2 Default Schedule

The default interval for this script is **Every 5 minutes**.

82.34.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Event?	Set to **y** to raise an event if the service is not running, if the restart attempt fails, or if the service is down and the *Auto-start service?* parameter is set to n. The default is y.
Collect data?	Set to **y** to collect data for charts and reports. If enabled, data collection returns: • **100** – the QoS/RSVP service is up, or • **0** – the service is down. These values are used to report the percentage of time the service is up in any given period. The default is n.
Auto-start service?	Set to **y** to automatically restart the QoS/RSVP service when it is down. The default is y.
Severity when auto-start fails	Set the event severity level, from 1 to 40, to indicate the importance of an event in which service is down and AppManager cannot restart it. The default is 5 (red event indicator).
Severity when auto-start succeeds	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the service was down and AppManager successfully restarted it. The default is 25 (blue event indicator).
Severity when auto-start is set to n	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the service is down and the *Auto-start service?* parameter is set to n. The default is 18 (yellow event indicator).
Severity for an unexpected KS error	Set the level between 1 and 40, to indicate the importance of an event in which the RSVPServiceDown job fails unexpectedly. The default is 35 (magenta event indicator).

82.35 SMTPEventLog

Use this Knowledge Script to periodically scan the Windows System log for SMTP-related events matching the criteria you specify.

Each time this script runs, it checks the System log for entries matching your selection criteria and raises an event if matching entries are found. The event detail message returns the text of the log entries found. When this script is set to collect data, it returns the number of log entries found, and the data point detail message returns the text of the log entries.

In the first interval, the value you specify for the *Start with events in past N hours* parameter determines how far back in the log to check for matching entries. As the script continues to run at subsequent intervals, it checks for any new entries created since the last time the log was checked.

You can further restrict the types of log entries that generate an event in two ways:

- Use the *Monitor for events of type [...]* parameters to search only certain types of events, such as Warning events.
- Use the *Filter the [...] field for* parameters to search only for specific information, such as events associated with a specific user or computer name.

82.35.1 Resource Object

SMTP folder

82.35.2 Default Schedule

The default interval for this script is **Every 10 minutes**.

82.35.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Event?	Set to **y** to raise an event if log entries match your search criteria. The default is y.
Collect data?	Set to **y** to collect data for charts and reports. If enabled, data collection returns the number of new event log entries. The default is n.
Start with events in past N hours	Set this parameter to determine which events are searched for the *first* time this script is run. Subsequent searches begin where the last search finished. The following entries are valid: • Enter -1 to search all current and previous System Log events during the first interval. • Enter 0 to search only for current events; previous events are not searched. • Enter the number of hours to go back in the System Log to scan for matching events. For example, enter 8 to scan the last 8 hours of the System Log for matching entries. The default is 0.

Parameter	How to Set It
Monitor for events of type:	Set to **y** for each type of event you want to monitor: • Error • Warning • Information • Success Audit • Failure Audit If you enable data collection or events, and set any of these parameters to n, this script does not raise an event or collect data for that type of log entry. The default is y.
Filter the [...] field for	To limit the types of entries that raise events and the type of data that is collected, enter a search string that filters the following fields in the event log: • **Category**. Specify text strings to look for in the Category field. Separate multiple strings with commas. • **Event ID**. Specify a single event ID or a range of event IDs. Separate multiple entries by commas. For example: `414,1028-1400,4015`. • **User**. Specify a search string to look for events associated with a particular user, for example, `<domain name>\<user name>`. Separate multiple strings with commas. For example: `USA\Tom,USA\Chris,EUROPE\Alex`. • **Computer**. Specify computer names to look for. Separate multiple entries by commas. For example: `SHASTA,MARS`. • **Event Description**. Specify a detail description or keywords in the description. The string can contain spaces, underscores, and periods. Separate multiple entries with commas. The search string can contain criteria used to include entries, exclude entries, or both. Separate the include and exclude criteria with a colon (:). If you are specifying only include criteria, the colon is not necessary.
Maximum number of entries per event message	Specify the maximum number of entries to be recorded in each event's detail message. If, during any interval when it scans the log, this script finds more entries in the log than can be put into a single event message, it raises multiple events to return all the log entries. The default is 30 entries.
Event severity	Set the event severity level, from 1 to 40, to indicate the importance of an event in which log entries match your search criteria. You can adjust the severity based on the types of events you are checking. The default is 8 (red event indicator).

82.36 SMTPQueues

Use this Knowledge Script to monitor the length of the following SMTP queues:

- Categorizer queue
- Local queue
- Local Retry queue
- Remote queue
- Remote Retry queue

This script raises an event if any queue length exceeds the threshold you set.

82.36.1 Resource Object

SMTP folder

82.36.2 Default Schedule

The default interval for this script is **Every 10 minutes**.

82.36.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Event?	Set to **y** to raise an event if a queue length exceeds the threshold you set. The default is y.
Collect data?	Set to **y** to collect data for charts and reports. If enabled, data collection returns the queue length for each SMTP queue. The default is n.
SMTP Categorizer queue length	Specify the maximum number of processes that can be in the SMTP Categorizer queue before an event is raised. The default is 10.
SMTP Local queue length	Specify the maximum number of processes that can be in the SMTP Local queue before an event is raised. The default is 10.
SMTP Local Retry queue length	Specify the maximum number of processes that can be in the SMTP Local Retry queue before an event is raised. The default is 5.
SMTP Remote queue length	Specify the maximum number of processes that can be in the SMTP Remote queue before an event is raised. The default is 10.
SMTP Remote Retry queue length	Specify the maximum number of processes that can be in the SMTP Remote Retry queue before an event is raised. The default is 5.
Event severity	Set the event severity level, from 1 to 40, to indicate the importance of an event in which a queue length exceeds the threshold you set. The default is 8 (red event indicator).

82.37 SMTPServiceDown

Use this Knowledge Script to monitor the up and down status of the SMTP service. You can set this script to automatically attempt to restart the service when it is not running. This script raises an event when auto-start fails, succeeds, or is disabled.

82.37.1 Resource Object

SMTP Service object

82.37.2 Default Schedule

The default interval for this script is **Every 5 minutes**.

82.37.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Event?	Set to **y** to raise an event when auto-start fails, succeeds, or is disabled. The default is y.
Collect data?	Set to **y** to collect data for charts and reports. If enabled, data collection returns: • **100** – the SMTP service is up, or • **0** – the service is down. These values are used to report the percentage of time the service is up in any given period. The default is n.
Auto-start service?	Set to **y** to automatically restart the SMTP service when it is down. The default is y.
Severity when auto-start fails	Set the event severity level, from 1 to 40, to indicate the importance of an event in which service is down and AppManager cannot restart it. The default is 5 (red event indicator).
Severity when auto-start succeeds	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the service was down and AppManager successfully restarted it. The default is 25 (blue event indicator).
Severity when auto-start is set to n	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the service is down and the *Auto-start service?* parameter is set to n. The default is 18 (yellow event indicator).
Severity for an unexpected KS error	Set the level between 1 and 40, to indicate the importance of an event in which the SMTPServiceDown job fails unexpectedly. The default is 35 (magenta event indicator).

83 WIN2003 Knowledge Scripts

The WIN2003 category provides Knowledge Scripts for monitoring computers running Microsoft Windows Server 2003 or later.

From the Knowledge Script view of Control Center, you can access more information about any NetIQ-supported Knowledge Script by selecting it and clicking **Help**. Or in the Operator Console, click any Knowledge Script in the Knowledge Script pane and press **F1**.

Knowledge Script	What It Does
ActivationGracePeriod	Monitors the number of days that remain before you are required to activate the Windows operating system.
AUDownLoaded	Monitors the number of critical Windows updates that have been downloaded but not yet installed
AUOptionChange	Monitors the Automatic Updates options.
AUServiceDown	Monitors the status of the Automatic Updates service
AUVerifyHotFix	Verifies whether specified hotfixes have been installed.
BITSJobProgress	Monitors the progress of Background Intelligent Transfer Service jobs by measuring the total bytes transferred and the total files transferred.
BITSJobsActive	Monitors the number of active Background Intelligent Transfer Service jobs.
BITSJobsError	Monitors the total number of Background Intelligent Transfer Service jobs that are in an error state.
BITSJobState	Indicates whether a Background Intelligent Transfer Service job is in error state or not in error state.
BITSJobStats	Monitors the number of times a Background Intelligent Transfer Service job is interrupted by network failure or server unavailability.
BITSServiceDown	Monitors the status of the Background Intelligent Transfer Service.
CLRConnectionPools	Monitors SQL connection pools in managed .NET applications.
CLRContention	Monitors the thread contention rate and thread queue length in managed .NET applications.
CLRExceptions	Monitors exceptions that managed .NET applications raise.
CLRHeap	Monitors heap memory use in managed .NET applications.
CLRJit	Monitors JIT (just-in-time) compilation in managed .NET applications.
CLRMemProfile	Monitors total garbage collection in managed .NET applications.
CLRContention	Monitors network activity in managed .NET applications.
CLRRemoting	Monitors remote procedure call (RPC) activity in managed .NET applications.

Knowledge Script	What It Does
CLRThreads	Monitors thread use in managed .NET applications.
CLRNetworking	Monitors the distributed COM (DCOM) application list.
FaxActivity	Monitors the number of faxes, fax pages, and fax bytes sent and received.
FaxEventLog	Scans the Windows Application event log for entries created by the Microsoft Fax service that match the criteria you specify.
FaxServiceDown	Monitors the status of the Microsoft Fax service.
FaxTotalFailed	Monitors the total number of failed faxes, failed outgoing connections, and failed receptions.
FaxTotalTime	Monitors the number of minutes the Microsoft Fax service spends receiving and sending faxes.
OpenSystemSlots	Monitors the number of available system (PCI) slots.
PNPDeviceChange	Monitors the plug-and-play device list for any device that has been added or removed since the script was last run.
PNPDeviceErrors	Monitors the number of plug-and-play devices that have a status of “error.”
PrinterStuckJobs	Monitors jobs that are stuck in the printer queue.
SRDiskPercent	Monitors the percentage of space on a disk available for the System Restore service.
SREventLog	Scans the Windows Application event log for entries created by the System Restore service that match the criteria you specify.
SRLifeInterval	Monitors the number of days the System Restore service preserves System Restore points
SRPoints	Monitors the number of System Restore points that are being preserved by the System Restore service.
SRScheduledInterval	Monitors the interval at which scheduled System Restore points are created during both current and global sessions.
SRServiceDown	Monitors the status of the System Restore service.

83.1 ActivationGracePeriod

Use this Knowledge Script to monitor the number of days that remain before you are required to activate the system. After you install Windows, you must activate your installation by contacting Microsoft. If you do not activate within a certain number of days, you can no longer log on.

This script raises an event if the number of days remaining falls below the threshold you set.

83.1.1 Resource Objects

Windows 2003 Server or later

83.1.2 Default Schedule

The default interval for this script is **Every 24 hours**.

83.1.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if number of days in grace period falls below threshold?	Set to **y** to raise an event when the number of days remaining before you must activate the system falls below the threshold you set. The default is y.
Collect data for days remaining in grace period?	Set to **y** to collect data for charts and reports. If enabled, data collection returns the number of days remaining before you must activate your system. The default is n.
Threshold – Minimum days remaining in grace period	Specify the minimum number of days that must remain before activation of the system is required to prevent an event from being raised. The default is 1 day.
Event severity when number of days falls below threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of days remaining before system activation is required falls below the threshold. The default is 5 (red event indicator).

83.2 AUDownLoaded

Use this Knowledge Script to monitor the total number of critical updates from the Windows update Web site that have been downloaded but not yet installed. If you configure Automatic Updates to prompt you before installing downloaded updates, then you may accumulate a large number of downloaded updates that have not yet been installed. This script raises an event if the total number of downloaded, but uninstalled, updates exceeds the threshold you set.

83.2.1 Resource Object

Automatic Updates folder

83.2.2 Default Schedule

The default interval for this script is **Every 24 hours**.

83.2.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if threshold is exceeded?	Set to **y** to raise an event if the total number of updates downloaded exceeds the threshold you set. The default is y.
Collect data for updates downloaded but not installed?	Set to **y** to collect data for charts and reports. If enabled, data collection returns the number of updates that have been downloaded but not yet installed. The default is n.
Threshold – Maximum total downloaded updates	Specify the maximum number of updates that can be downloaded but not installed before an event is raised. The default is 10.
Event severity when downloaded updates exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of updates that can be downloaded but not installed exceeds the threshold. The default is 8 (red event indicator).

83.3 AUOptionChange

Use this Knowledge Script to monitor the Automatic Updates options. You can configure several Automatic Updates options:

- Disabled
- Notify user before download and install
- Download automatically and notify before install
- Automatically download and install on schedule

This script raises an event is raised if an option setting is changed.

83.3.1 Resource Object

Automatic Updates folder

83.3.2 Default Schedule

The default interval for this script is **Every hour**.

83.3.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if Automatic Updates option changed?	Set to **y** to raise an event when an option setting is changed. The default is y.
Collect data for Automatic Updates options changed?	Set to **y** to collect data for charts and reports. If enabled, data collection returns the current selections for the Automatic Updates options. The default is n.
Event severity when option changed	Set the event severity level, from 1 to 40, to indicate the importance of an event in which Automatic Updates options have changed. The default is 8 (red event indicator).

83.4 AUServiceDown

Use this Knowledge Script to monitor the status of the Automatic Updates service. This script raises an event if the service is down, and can, optionally, attempt to restart the service when it is not running.

83.4.1 Resource Object

Automatic Updates Service object

83.4.2 Default Schedule

The default interval for this script is **Every 5 minutes**.

83.4.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if Automatic Updates service is down?	Set to **y** to raise an event when the Automatic Updates service is down. The default is y.
Collect data for service status?	Set to **y** to collect data for charts and reports. If enabled, data collection returns: • 100 – service is running, or • 0 – service is not running. The default is n.
Auto-start service if down?	Set to **y** to automatically restart the service when it is down. The default is y.
Event severity when auto-start fails	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the service is down and AppManager cannot restart it. The default is 5 (red event indicator).
Event severity when auto-start succeeds	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the service was down and AppManager successfully restarted it. The default is 25 (blue event indicator).
Event severity when service down and auto-start disabled	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the service is down and AppManager has been set to not restart the service. The default is 18 (yellow event indicator).

83.5 AUVerifyHotFix

Use this Knowledge Script to verify whether the hotfixes you specify have been installed. This script raises an event when specified hotfixes have not been installed and when specified hotfixes are installed.

83.5.1 Resource Object

Automatic Updates folder

83.5.2 Default Schedule

The default interval for this script is once.

83.5.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Hotfix articles to monitor	Specify the ID for each hotfix you want to verify. You can enter multiple IDs separated by commas. **NOTE:** The ID for each hotfix is case-sensitive. For example, Q123456 is *not* a match for q123456. If your entry does not exactly match the hotfix ID, an event is raised indicating the hotfix in question has not been installed even if it has been installed.
Raise event when hotfixes are installed?	Set to **y** to raise an event when the hotfixes you specify have been installed. The default is y.
Event severity when hotfixes are installed	Set the event severity level, from 1 to 40, to indicate the importance of an event in which specified hotfixes have been installed. The default is 15 (yellow event indicator).
Raise event if hotfixes have not been installed?	Set to **y** to raise an event when the hotfixes you specify have not yet been installed. The default is y.
Event severity when hotfixes have not been installed	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the hotfixes you specified have not been installed. The default is 8 (red event indicator).
Collect data for installed hotfixes?	Set to **y** to collect data for charts and reports. If enabled, data collection returns the number of installed hotfixes. The default is n.

83.6 BITSJobProgress

Use this Knowledge Script to monitor the progress of Background Intelligent Transfer Service (BITS) jobs by measuring the total bytes transferred and the total files transferred. This script raises an event if the total number of bytes or files transferred exceeds the thresholds you set.

83.6.1 Prerequisites

For Windows Sever 2008 and Windows 2008 R2 or later, you can run this script on both 32-bit and 64-bit platforms. For older versions of Windows, you can only run this script on 32-bit platforms.

This script requires version 2.0 or later of Windows .NET Framework on the computer you want to monitor.

83.6.2 Resource Objects

BITS Jobs object

83.6.3 Default Schedule

The default interval for this script is **Every 5 minutes**.

83.6.4 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if threshold is exceeded?	Set to **y** to raise an event if the total bytes transferred or the total files transferred exceed the threshold you set. The default is y.
Collect data for total bytes and files transferred by BITS jobs?	Set to **y** to collect data for charts and reports. If enabled, data collection returns total bytes transferred and total files transferred for a BITS job. The default is n.
Threshold – Maximum number of bytes transferred by BITS jobs	Specify the maximum number of bytes that can be transferred before an event is raised. The default is 200 bytes.
Threshold – Maximum number of files transferred by BITS jobs	Specify the maximum number of files that can be transferred before an event is raised. The default is 200 files.
Event severity when threshold exceeded	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of transferred bytes or jobs exceeds the threshold you set. The default is 8 (red event indicator).

83.7 BITSJobsActive

Use this Knowledge Script to monitor the number of active BITS jobs. This script raises an event when the total number of active jobs exceeds the threshold.

83.7.1 Prerequisites

For Windows Sever 2008 and Windows 2008 R2 or later, you can run this script on both 32-bit and 64-bit platforms. For older versions of Windows, you can only run this script on 32-bit platforms.

This script requires version 2.0 or later of Windows .NET Framework on the computer you want to monitor.

83.7.2 Resource Object

BITS folder

83.7.3 Default Schedule

The default interval for this script is **Every 5 minutes**.

83.7.4 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if number of active BITS jobs exceeds threshold?	Set to **y** to raise an event when the total number of active BITS jobs exceeds the threshold you set. The default is y.
Collect data for number of active BITS jobs?	Set to **y** to collect data for charts and reports. If enabled, data collection returns the number of jobs submitted and the number of incomplete jobs during the interval you specify. The default is n.
Threshold – Maximum number of active BITS jobs	Specify the maximum number of BITS jobs that can be active before an event is raised. The default is 200 jobs.
Event severity when number of active BITS jobs exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of active BITS jobs exceeds the threshold. The default is 8 (red event indicator).

83.8 BITSJobsError

Use this Knowledge Script to monitor the total number of BITS jobs that are in an error state. This script raises an event if the number of BITS jobs with the status of error exceeds the threshold.

83.8.1 Prerequisites

For Windows Sever 2008 and Windows 2008 R2 or later, you can run this script on both 32-bit and 64-bit platforms. For older versions of Windows, you can only run this script on 32-bit platforms.

This script requires version 2.0 or later of Windows .NET Framework on the computer you want to monitor.

83.8.2 Resource Object

BITS folder

83.8.3 Default Schedule

The default interval for this script is **Every 5 minutes**.

83.8.4 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if number of BITS jobs in error state exceeds threshold?	Set to **y** to raise an event when the number of BITS jobs with the status of error exceeds the threshold you set. The default is y.
Collect data for BITS jobs in error state?	Set to **y** to collect data for charts and reports. If enabled, data collection returns the number of BITS jobs that have the status of error. The default is n.
Threshold – Maximum number of BITS jobs in error state	Specify the maximum number of BITS jobs that can have a status of error before an event is raised. The default is 10.
Event severity when BITS jobs in error state exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of BITS job with a status of error exceeds the threshold. The default is 8 (red event indicator).

83.9 BITSJobState

Use this Knowledge Script to monitor the state of a BITS job. This script raises an event if a BITS job is in error state and when it is not in error state.

83.9.1 Prerequisites

For Windows Sever 2008 and Windows 2008 R2 or later, you can run this script on both 32-bit and 64-bit platforms. For older versions of Windows, you can only run this script on 32-bit platforms.

This script requires version 2.0 or later of Windows .NET Framework on the computer you want to monitor.

83.9.2 Resource Object

BITS Job object

83.9.3 Default Schedule

The default interval for this script is **Every 5 minutes**.

83.9.4 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if BITS job is in error state?	Set to **y** to raise an event when the BITS job is in the error state. The default is y.
Raise event if BITS job is not in error state?	Set to **y** to raise an event when the BITS job is not in the error state. The default is y.
Collect data for status of BITS job?	Set to **y** to collect data for charts and reports. If enabled, data collection returns the state of the BITS job: canceled, executing, completed, or error. The default is n.
Event severity when BITS job in error state	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the BITS job is in an error state. The default is 8 (red event indicator).
Event severity when BITS job not in error state	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the BITS job is not in an error state. The default is 25 (blue event indicator).

83.10 BITSJobStats

Use this Knowledge Script to monitor the number of times the BITS job is interrupted by network failure or server unavailability. This script raises an event is raised if the total number of times the BITS job is interrupted exceeds the threshold.

83.10.1 Prerequisites

For Windows Sever 2008 and Windows 2008 R2 or later, you can run this script on both 32-bit and 64-bit platforms. For older versions of Windows, you can only run this script on 32-bit platforms.

This script requires version 2.0 or later of Windows .NET Framework on the computer you want to monitor.

83.10.2 Resource Object

BITS Jobs object

83.10.3 Default Schedule

The default interval for this script is **Every 5 minutes**.

83.10.4 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if interruptions exceed threshold?	Set to **y** to raise an event when the number of times the BITS job is interrupted exceeds the threshold you set. The default is y.
Collect data for number of BITS job interruptions?	Set to **y** to collect data for charts and reports. If enabled, data collection returns the number of times the BITS job is interrupted. The default is n.
Threshold – Maximum number of BITS job interruptions	Specify the maximum number of times the BITS job can be interrupted before an event is raised. The default is 10 times.
Event severity when interruptions exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of times the BITS job is interrupted exceeds the threshold. The default is 8 (red event indicator).

83.11 BITSServiceDown

Use this Knowledge Script to monitor the status of the BITS service. This script raises an event if the service is down, and can restart the service when it is not running.

83.11.1 Resource Objects

BITS service object

83.11.2 Default Schedule

The default interval for this script is **Every 5 minutes**.

83.11.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if BITS service is down?	Set to **y** to raise an event when the BITS service is down. The default is y.
Collect data for BITS service status?	Set to **y** to collect data for charts and reports. If enabled, data collection returns a value of 100 if the service is running, and a value of 0 if the service is not running. The default is n.
Auto-start service?	Set to **y** to automatically restart the service when it is down. The default is y.
Event severity when auto-start fails	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the service is down and AppManager cannot restart it. The default is 5 (red event indicator).
Event severity when auto-start succeeds	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the service was down and AppManager successfully restarted it. The default is 25 (blue event indicator).
Event severity when service down and auto-start disabled	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the service is down and AppManager has been set to not restart the service. The default is 18 (yellow event indicator).

83.12 CLRConnectionPools

Use this Knowledge Script to monitor SQL connection pools in managed .NET applications. Connection pools are caches of stored database connections that are reused, eliminating the need to create new connections each time a new request is received.

This script raises an event if either of the following conditions exists:

- The highest number of pooled connections in a session exceeds a specified threshold.
- The total number of connection attempts that failed exceeds a specified threshold.

NOTE: The monitored .NET applications must be running at the time of discovery so their resource objects can be discovered. The applications must also be running for this script to collect data.

83.12.1 Default Schedule

The default schedule for this script is **Every 5 minutes**.

83.12.2 Resource Objects

SQL Client Managed Applications folder

SQL Client Managed Applications object

83.12.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Raise event if the managed application is not running?	Set to **Yes** to raise an event if the managed application is not running. The default is Yes.
Event severity when application is not running	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the managed application is not running. The default is 20 (yellow event indicator).
Monitor Peak Pooled Connection	
Event Notification	
Raise event if peak pooled connections exceed threshold?	Set to **Yes** to raise an event if the number of pooled connections exceeds the threshold you set. The default is Yes.
Threshold – Maximum peak pooled connections	Specify the maximum number of pooled connections that can occur before an event is raised. The default is 64 connections.
Event severity when peak pooled connections exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of pooled connections exceeds the threshold. The default is 15 (yellow event indicator).

Parameter	How to Set It
Data Collection	
Collect data for peak pool connection?	Set to **Yes** to collect data for charts and reports. When enabled, data collection returns the maximum number of pool connections that occurred during the monitoring interval. The default is unselected.
Monitor Failed Connection	
Event Notification	
Raise event if failed connections exceed threshold?	Set to **Yes** to raise an event if the number of failed connections exceeds the threshold you set. The default is Yes.
Threshold – Maximum failed connections	Specify the maximum of connections that can fail before an event is raised. The default is 4 connections.
Event severity when failed connections exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of failed connections exceeds the threshold. The default is 15 (yellow event indicator).
Data Collection	
Collect data for failed connections?	Set to **Yes** to collect data for charts and reports. When enabled, data collection returns the number of connections that failed during the monitoring interval. The default is unselected.
Monitor General Connection Pool	
Data Collection	
Collect data for current connection pool?	Set to **Yes** to collect data for charts and reports. When enabled, data collection returns the number of current connection pools. The default is unselected.
Collect data for pooled connections?	Set to **Yes** to collect data for charts and reports. When enabled, data collection returns the number of pooled connections. The default is unselected.

83.13 CLRContention

Use this Knowledge Script to monitor the thread contention rate and thread queue length in managed .NET applications.

This script raises an event if one of the following conditions exists:

- The contention rate (in seconds) exceeds a specified threshold. Contention occurs when numerous threads compete unsuccessfully to acquire managed locks at run time.
- The thread queue length exceeds a specified threshold. Thread queue length is a measurement of all threads that are waiting to acquire a managed lock on an application.

NOTE: The monitored .NET applications must be running at the time of discovery so their resource objects can discovered. The applications must also be running for this script to collect data.

83.13.1 Default Schedule

The default schedule for this script is **Every 5 minutes**.

83.13.2 Resource Objects

Managed Applications folder

Managed Applications object

83.13.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Raise event if application not running?	Set to **Yes** to raise an event if the managed application is not running. The default is Yes.
Event severity when application not running	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the managed application is not running. The default is 20 (yellow event indicator).
Monitor Contention Rate	
Event Notification	
Raise event if contention rate exceeds threshold?	Set to **Yes** to raise an event if the contention rate exceeds the threshold you set. The default is Yes.
Threshold – Maximum contention rate	Specify the maximum number of contentions that can occur per second before an event is raised. The default is one contention per second.
Event severity when contention rate exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the contention rate exceeds the threshold. The default is 15 (yellow event indicator).

Parameter	How to Set It
Data Collection	
Collect data for contention rate?	Set to **Yes** to collect data for charts and reports. When enabled, data collection returns the contention rate for the monitoring interval. The default is unselected.
Monitor Thread Queue Length	
Event Notification	
Raise event if thread queue length exceeds threshold?	Set to **Yes** to raise an event if the thread queue length exceeds the threshold you set. The default is Yes.
Threshold – Maximum thread queue length	Specify the maximum number of threads that can be in the queue before an event is raised. The default is 10 threads.
Event severity when thread queue length exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of threads in the queue exceeds the threshold. The default is 15 (yellow event indicator).
Data Collection	
Collect data for thread queue length?	Set to **Yes** to collect data for charts and reports. When enabled, data collection returns the number of threads in queue during the monitoring interval. The default is unselected.

83.14 CLRExceptions

Use this Knowledge Script to monitor exceptions that managed .NET applications raise. Exceptions are errors in a program that cause it to branch to a new routine.

This script raises an event if one of the following conditions occurs:

- The total number of .NET exceptions (or converted exceptions) that occur since the application started exceeds a specified threshold.
- The number of .NET exceptions (or converted exceptions) that occur per second exceeds a specified threshold.

NOTE: The monitored .NET applications must be running at the time of discovery so their resource objects can discovered. The applications must also be running for this script to collect data.

83.14.1 Default Schedule

The default schedule for this script is **Every 5 minutes**.

83.14.2 Resource Objects

Managed Applications folder

Managed Applications object

83.14.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Raise event if application not running?	Set to **Yes** to raise an event if the managed application is not running. The default is Yes.
Event severity when application not running	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the managed application is not running. The default is 20 (yellow event indicator).
Monitor Exception Count	
Event Notification	
Raise event if exceptions exceed threshold?	Set to **Yes** to raise an event if the number of exceptions exceeds the threshold you set. The default is Yes.
Threshold – Maximum number of exceptions	Specify the maximum number of exceptions that can occur before an event is raised. The default is 5 exceptions.
Event severity when exceptions exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of exceptions exceeds the threshold. The default is 15 (yellow event indicator).

Parameter	How to Set It
Data Collection	
Collect data for number of exceptions?	Set to **Yes** to collect data for charts and reports. When enabled, data collection returns the number of exceptions that occurred during the monitoring period. The default is unselected.
Monitor Exception Rate	
Event Notification	
Raise event if exception rate exceeds threshold?	Set to **Yes** to raise an event if the exception rate exceeds the threshold you set. The default is Yes.
Threshold – Maximum exception rate	Specify the maximum number exceptions allowed per second before an event is raised. The default is 10 exceptions per second.
Event severity when exception rate exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the exception rate exceeds the threshold. The default is 15 (yellow event indicator).
Data Collection	
Collect data for exception rate?	Set to **Yes** to collect data for charts and reports. When enabled, data collection returns the exception rate during the monitoring interval. The default is unselected.

83.15 CLRHeap

Use this Knowledge Script to monitor heap memory use in managed .NET applications.

This script raises an event if one of the following occurs:

- Full garbage collection levels have changed. Total garbage collection frees memory slots in sections of unused memory and is composed of partial garbage collection (where memory freeing processes can be interrupted) and full garbage collection (where memory freeing processes cannot be interrupted). In partial garbage collection, only the most recently allocated objects (Gen 0 objects) are counted. In full garbage collection, older objects (Gen 1 and up) are counted.
- Special heap memory use is greater than a specified percentage of the total garbage collection heap. In some cases, garbage collection software allocates large objects (>20 KB) directly to an area in memory known as the special heap, bypassing generation object promotion.

NOTE: The monitored .NET applications must be running at the time of discovery so their resource objects can discovered. The applications must also be running for this script to collect data.

83.15.1 Default Schedule

The default schedule for this script is **Every 5 minutes**.

83.15.2 Resource Objects

Managed Applications folder

Managed Applications object

83.15.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Raise event if application not running?	Set to **Yes** to raise an event if the managed application is not running. The default is Yes.
Event severity when application not running	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the managed application is not running. The default is 20 (yellow event indicator).
Monitor heap memory usage	
Event Notification	
Raise event if special heap size exceeds threshold?	Set to **Yes** to raise an event if the special heap size exceeds the threshold you set. The default is Yes.
Threshold – Maximum size of special heap (as % of garbage heap)	Specify the maximum size of the special heap (as a percentage of the total heap) that can occur before an event is raised. The default is 80%. Total heap is the number of bytes in all heaps.

Parameter	How to Set It
Event severity when size of special heap exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the size of the special heap exceeds the threshold. The default is 15 (yellow event indicator).
Data Collection	
Collect data for total heap size?	Set to **Yes** to collect data for charts and reports. When enabled, data collection returns the size of the total heap during the monitoring interval. The default is unselected.
Monitor Full Garbage Collection	
Event Notification	
Raise event if frequency of full garbage collection changes?	Set to **Yes** to raise an event if the number of full garbage collections has changed since the last time the script ran. The default is Yes.
Event severity when full garbage collection frequency changes	Set the event an event in which the number of full garbage collections has changed. The default is 15 (yellow event indicator).

83.16 CLRJit

Use this Knowledge Script to monitor JIT (just-in-time) compilation in managed .NET applications.

This script raises an event if one of the following conditions exists:

- The number of bytes per second that undergo JIT compilation (JIT byte rate) is less than a specified threshold. The JIT byte rate is the difference between the last two samples divided by the number of seconds in the interval.
- The percent of time spent in JIT compilation since the application started exceeds a specified threshold.

NOTE: The monitored .NET applications must be running at the time of discovery so their resource objects can discovered. The applications must also be running for this script to collect data.

83.16.1 Default Schedule

The default schedule for this script is **Every 15 minutes**.

83.16.2 Resource Objects

Managed Applications folder

Managed Applications object

83.16.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Raise event if application not running?	Set to **Yes** to raise an event if the managed application is not running. The default is Yes.
Event severity when application not running	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the managed application is not running. The default is 20 (yellow event indicator).
Monitor JIT Byte Rate	
Event Notification	
Raise event if JIT byte rate falls below threshold?	Set to **Yes** to raise an event if the JIT byte rate falls below the threshold you set. The default is Yes.
Threshold – Minimum JIT byte rate	Specify the minimum number of JIT bytes that must occur per second to prevent an event from being raised. The default is 512 bytes per second.
Event severity when JIT byte rate falls below threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the JIT byte rate falls below the threshold. The default is 15 (yellow event indicator).

Parameter	How to Set It
Data Collection	
Collect data for JIT byte rate?	Set to **Yes** to collect data for charts and reports. When enabled, data collection returns the JIT byte rate for the monitoring interval. The default is unselected.
Monitor Percent of Time in JIT	
Event Notification	
Raise event if percent of time spent in JIT compilation exceeds threshold?	Set to **Yes** to raise an event if the amount of time the application spends in JIT compilation exceeds the threshold you set. The default is Yes.
Threshold – Maximum percent of time spent in JIT compilation	Specify the maximum percentage of time the application can spend in JIT compilation before an event is raised. The default is 60%.
Event severity when time spent in JIT compilation exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the amount of time the application spends in JIT compilation exceeds the threshold. The default is 15 (yellow event indicator).
Data Collection	
Collect data for percent of time in JIT compilation?	Set to **Yes** to collect data for charts and reports. When enabled, data collection returns the amount of time the application spends in JIT compilation during the monitoring interval. The default is unselected.

83.17 CLRMemProfile

Use this Knowledge Script to monitor total garbage collection in managed .NET applications.

Total garbage collection frees memory slots in sections of unused memory and is composed of partial garbage collection (where memory freeing processes can be interrupted) and full garbage collection (where memory freeing processes cannot be interrupted).

In partial garbage collection, only the most recently allocated objects (Gen 0 objects) are counted.

In full garbage collection, older objects (Gen 1 and up) are counted.

This script raises an event if the total garbage collection time since the previous collection exceeds a specified percentage.

NOTE: The monitored .NET applications must be running at the time of discovery so their resource objects can discovered. The applications must also be running for this script to collect data.

83.17.1 Default Schedule

The default schedule for this script is **Every 5 minutes**.

83.17.2 Resource Objects

Managed Applications folder

Managed Applications object

83.17.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Raise event if application not running?	Set to **Yes** to raise an event if the managed application is not running. The default is Yes.
Event severity when application not running	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the managed application is not running. The default is 20 (yellow event indicator).
Monitor Garbage Collection Time	
Event Notification	
Raise event if percentage of time spent in garbage collection exceeds threshold?	Set to **Yes** to raise an event if the percent of time spent in garbage collection exceeds the threshold you set. The default is Yes.
Threshold – Maximum percentage of time spent in garbage collection	Specify the maximum amount of time the application should spend in garbage collection before an event is raised. The default is 6%.

Parameter	How to Set It
Event severity when garbage collection time exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the percent of time spent in garbage collection exceeds the threshold. The default is 15 (yellow event indicator).
Data Collection	
Collect data for memory profile?	Set to **Yes** to collect data for charts and reports. When enabled, data collection returns the amount of time spent in garbage collection during the monitoring interval. The default unselected.

83.18 CLRNetworking

Use this Knowledge Script to monitor network activity in managed .NET applications.

This script raises an event if one of the following conditions exists:

- The number of bytes sent during a process, through all socket connections, exceeds a specified threshold. The number of bytes includes data as well as non-TCP/IP protocol information.
- The number of bytes received during a process, through all socket connections, exceeds a specified threshold. The number of bytes includes data as well as non-TCP/IP protocol information.

NOTE: The monitored .NET applications must be running at the time of discovery so their resource objects can discovered. The applications must also be running for this script to collect data.

83.18.1 Default Schedule

The default schedule for this script is **Every 5 minutes**.

83.18.2 Resource Objects

Networking Managed Applications folder

Networking Managed Applications object

83.18.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Raise event if application not running?	Set to **Yes** to raise an event if the managed application is not running. The default is Yes.
Event severity when application not running	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the managed application is not running. The default is 20 (yellow event indicator).
Monitor Network Traffic	
Event Notification	
Raise event if network bytes sent exceed threshold?	Set to **Yes** to raise an event if the number of bytes sent during a process exceeds the threshold you set. The default is Yes.
Threshold – Maximum number of network bytes sent	Specify the maximum number of bytes that can be sent during a process before an event is raised. The default is 1000000 bytes.
Event severity when network bytes sent exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of bytes sent during a process exceeds the threshold. The default is 15 (yellow event indicator).

Parameter	How to Set It
Raise event if network bytes received exceed threshold?	Set to **Yes** to raise an event if the number of bytes received during a process exceeds a specified threshold. The default is Yes.
Threshold – Maximum number of network bytes received	Specify the maximum number of bytes that can be received during a process before an event is raised. The default is 1000000 bytes.
Event severity when network bytes received exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of bytes received during a process exceeds the threshold. The default is 15 (yellow event indicator).
Data Collection	
Collect data for network byte sent?	Set to **Yes** to collect data for charts and reports. When enabled, data collection returns the number of bytes sent during the monitoring interval. The default is unselected.
Collect data for network byte received?	Set to **Yes** to collect data for charts and reports. When enabled, data collection returns the number of bytes received during the monitoring interval. The default is unselected.

83.19 CLRRemoting

Use this Knowledge Script to monitor remote procedure call (RPC) activity in managed .NET applications. An RPC is a type of protocol that enables a software program to execute on a remote server.

This script raises an event if the number of RPC calls per second (the RPC call rate) exceeds the threshold you set. The RPC call rate is the difference between the last two samples divided by the number of seconds in the interval.

NOTE: The monitored .NET applications must be running at the time of discovery so their resource objects can discovered. The applications must also be running for this script to collect data.

83.19.1 Default Schedule

The default schedule for this script is **Every 5 minutes**.

83.19.2 Resource Objects

Managed Applications folder

Managed Applications object

83.19.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Raise event if application not running?	Set to **Yes** to raise an event if the managed application is not running. The default is Yes.
Event severity when application not running	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the managed application is not running. The default is 20 (yellow event indicator).
Monitor Remote Procedure Call Rate	
Event Notification	
Raise event if RPC rate exceeds threshold?	Set to **Yes** to raise an event if the number of RPCs per second exceeds the threshold you set. The default is Yes.
Threshold – Maximum RPC rate	Specify the maximum number of RPCs that can occur per second before an event is raised. The default is 32 calls per second.
Event severity when RPC rate exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of RPC calls per second exceeds the threshold. The default is 15 (yellow event indicator).
Data Collection	
Collect data for RPC rate?	Set to **Yes** to collect data for charts and reports. When enabled, data collection returns the RPC rate for the monitoring interval. The default is unselected.

83.20 CLRThreads

Use this Knowledge Script to monitor thread use in managed .NET applications. This script raises an event if one of the following conditions exists:

- The total number of threads (total recognized threads) that have run at least once since the application started exceeds a specified threshold.
- The rate at which processors are assigned to alternate threads (context switch rate) exceeds a specified threshold. For example, the kernel can reassign an operation when a thread with higher priority becomes available.

NOTE: The monitored .NET applications must be running at the time of discovery so their resource objects can discovered. The applications must also be running for this script to collect data.

83.20.1 Default Schedule

The default schedule for this script is **Every 5 minutes**.

83.20.2 Resource Objects

Managed Applications folder

Managed Applications object

83.20.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
General Settings	
Raise event if application not running?	Set to **Yes** to raise an event if the managed application is not running. The default is Yes.
Event severity when application not running	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the managed application is not running. The default is 20 (yellow event indicator).
Monitor Thread Count	
Event Notification	
Raise event if thread count exceeds threshold?	Set to **Yes** to raise an event if the number threads that have run at least once exceeds the threshold you set. The default is Yes.
Threshold – Maximum thread count	Specify the maximum number of threads that can run before an event is raised. The default is 32 threads.
Event severity when thread count exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of threads exceeds the threshold. The default is 15 (yellow event indicator).

Parameter	How to Set It
Data Collection	
Collect data for thread count?	Set to **Yes** to collect data for charts and reports. When enabled, data collection returns the number of threads that ran at least once during the monitoring interval. The default is unselected.
Monitor Context Switch Rate	
Event Notification	
Raise event if context switch rate exceeds threshold?	Set to **Yes** to raise an event if the switch rate exceeds the threshold you set. The default is Yes.
Threshold – Maximum context switch rate	Specify the maximum rate at which processors can be assigned to alternate thread before an event is raised. The default is 4096 switches per second.
Event severity when context switch rate exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the switch rate exceeds the threshold. The default is 15 (yellow event indicator).
Data Collection	
Collect data for context switch rate?	Set to **Yes** to collect data for charts and reports. When enabled, data collection returns the context switch rate for the monitoring interval. The default is unselected.

83.21 DCOMAppChange

Use this Knowledge Script to monitor the distributed COM (DCOM) application list. This script raises an event if an application has been added or removed (registered or unregistered) from the application list on the target computer since the last time the script was run.

83.21.1 Resource Objects

Windows 2003 Server or later

83.21.2 Default Schedule

The default interval for this script is **Every 24 hours**.

83.21.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if DCOM applications added or removed?	Set to **y** to raise an event when one or more applications have been added to or removed from the DCOM application list. The default is y.
Collect data for DCOM applications added or removed?	Set to **y** to collect data for charts and reports. If enabled, data collection returns the number of DCOM applications currently registered. The default is n.
Event severity when DCOM applications added or removed	Set the event severity level, from 1 to 40, to indicate the importance of an event in which applications have been added to or removed from the DCOM application list. The default is 5 (red event indicator).

83.22 FaxActivity

Use this Knowledge Script to monitor the total number of faxes, fax pages, and fax bytes sent and received. This script raises events if the number of faxes, fax pages, or fax bytes sent and received exceeds the thresholds you set.

83.22.1 Resource Object

Fax folder

83.22.2 Default Schedule

The default interval for this script is **Every 15 minutes**.

83.22.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if number of bytes received exceeds threshold?	Set to **y** to raise an event when the number of received fax bytes exceeds the threshold you set. The default is y.
Raise event if number of bytes sent exceeds threshold?	Set to **y** to raise an event when the number of sent fax bytes exceeds the threshold you set. The default is y.
Raise event if number of faxes received exceeds threshold?	Set to **y** to raise an event when the number of received faxes exceeds the threshold you set. The default is y.
Raise event if number of faxes sent exceeds threshold?	Set to **y** to raise an event when the number of sent faxes exceeds the threshold you set. The default is y.
Raise event if number of pages received exceeds threshold?	Set to **y** to raise an event when the number of received fax pages exceeds the threshold you set. The default is y.
Raise event if number of pages sent exceeds threshold?	Set to **y** to raise an event when the number of sent fax pages exceeds the threshold you set. The default is y.
Raise event if total number of bytes sent and received exceeds threshold?	Set to **y** to raise an event when the number of total number of sent and received fax bytes exceeds the threshold you set. The default is y.
Raise event if total number of faxes sent and received exceeds threshold?	Set to **y** to raise an event when the number of total number of sent and received faxes exceeds the threshold you set. The default is y.
Raise event if total number of pages sent and received exceeds threshold?	Set to **y** to raise an event when the number of total number of sent and received fax pages exceeds the threshold you set. The default is y.

Parameter	How to Set It
Threshold – Maximum number of bytes received	Specify the maximum number of fax bytes that can be received before an event is raised. The default is 20000 bytes.
Threshold – Maximum number of bytes sent	Specify the maximum number of fax bytes that can be sent before an event is raised. The default is 20000 bytes.
Threshold – Maximum number of faxes received	Specify the maximum number of fax bytes that can be received before an event is raised. The default is 20000 bytes.
Threshold – Maximum number of faxes sent	Specify the maximum number of faxes that can be sent before an event is raised. The default is 20000 faxes.
Threshold – Maximum number of fax pages received	Specify the maximum number of fax pages that can be received before an event is raised. The default is 20000 pages.
Threshold – Maximum number of fax pages sent	Specify the maximum number of fax pages that can be sent before an event is raised. The default is 20000 pages.
Threshold – Maximum total fax bytes sent and received	Specify the maximum total number of fax bytes that can be sent and received before an event is raised. The default is 20000 bytes.
Threshold – Maximum total faxes sent and received	Specify the maximum total number of faxes that can be sent and received before an event is raised. The default is 20000 faxes.
Threshold – Maximum total fax pages sent and received	Specify the maximum total number of fax pages that can be sent and received before an event is raised. The default is 20000 pages.
Collect data for number of bytes received?	Set to **y** to collect data for charts and reports. If enabled, data collection returns the number of fax bytes received during the monitoring interval. The default is n.
Collect data for number of bytes sent?	Set to **y** to collect data for charts and reports. If enabled, data collection returns the number of fax bytes sent during the monitoring interval. The default is n.
Collect data for number of faxes received?	Set to **y** to collect data for charts and reports. If enabled, data collection returns the number of faxes received during the monitoring interval. The default is n.
Collect data for number of faxes sent?	Set to **y** to collect data for charts and reports. If enabled, data collection returns the number of faxes sent during the monitoring interval. The default is n.
Collect data for number of pages received?	Set to **y** to collect data for charts and reports. If enabled, data collection returns the number of fax pages received during the monitoring interval. The default is n.
Collect data for number of pages sent?	Set to **y** to collect data for charts and reports. If enabled, data collection returns the number of fax pages sent during the monitoring interval. The default is n.
Collect data for total number of bytes?	Set to **y** to collect data for charts and reports. If enabled, data collection returns the total number of fax bytes sent and received during the monitoring interval. The default is n.
Collect data for total number of faxes?	Set to **y** to collect data for charts and reports. If enabled, data collection returns the total number of faxes sent and received during the monitoring interval. The default is n.
Collect data for total number of pages?	Set to **y** to collect data for charts and reports. If enabled, data collection returns the total number of fax pages sent and received during the monitoring interval. The default is n.
Event severity when any threshold exceeded	Set the event severity level, from 1 to 40, to indicate the importance of an event in which a threshold is exceeded. The default is 8 (red event indicator).

83.23 FaxEventLog

Use this Knowledge Script to periodically scan the Windows Application event log for entries created by the Microsoft Fax service that match the criteria you specify. If any events are found, AppManager raises an event, and the event detail message provides more information about the event.

In the first interval, the value you specify for the *Start with events in past N hours* parameter determines how far back in the log to check for matching entries. As the job continues to run at subsequent intervals, it checks for any new entries created since the last time the log was checked.

You can further restrict the types of log entries that generate an event in two ways:

- Use the *Monitor for events of type [...]* parameters to search only certain types of events, such as Warning events.
- Use the *Filter the [...] field for* parameters to search only for specific information, such as events associated with a specific user or computer name.

83.23.1 Resource Object

Fax folder

83.23.2 Default Schedule

The default interval for this script is **Every 30 minutes**.

83.23.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if Fax service event log entries found?	Set to **y** to raise an event if the event log contains entries that match your search criteria. The default is y.
Collect data for Fax service entries?	Set to **y** to collect data for charts and reports. When enabled, data collection returns the number of log entries found, and the data point detail message returns the text of the log entries. The default is n.
Start with events in past N hours	Use this parameter to determine which part of the event log is searched the *first* time you run the job. Subsequent searches begin where the previous one finished. The following entries are valid: • **-1** to search all existing log entries during the first interval • **n** to search entries for the past *n* hours (8 for the past 8 hours, 50 for the past 50 hours, for example.) • **0** to search no previous entries (search from the current time forward) The default is 0.

Parameter	How to Set It
Monitor for events of type:	Set to **y** for each type of event you want to monitor: • Error • Warning • Information • Success Audit • Failure Audit If you disable any of these event types, that type of log entry does not raise an event, is not returned in an event detail message, and is not collected as data if you enabled *Collect data for Fax service entries?* The default is y.
Filter the [...] field for	To limit the types of entries that raise events and the type of data that is collected, enter a search string that filters the following fields in the event log: • **Category**. Specify one or more text strings to look for in the Category field. Separate multiple strings with commas. • **Event ID**. Specify single or multiple event IDs. Separate multiple entries with commas. To specify a range of event IDs, use a hyphen. For example: `414,1028-1400,4015`. • **User**. Specify a single or multiple user names to look for. Separate multiple entries by commas. For example: `Pat,Chris,Alex`. • **Computer**. Specify a single or multiple computer names or IP addresses to look for. Separate multiple entries by commas. For example: `SHASTA,MARS`. • **Event Description**. Specify a description or keywords in the description. The string can contain spaces, underscores, and periods. Separate multiple entries with commas. For example: `no domain,critical error from the Active Directory`. The search string can contain criteria used to include entries, exclude entries, or both. • Separate the include and exclude criteria with a colon (:). For example, `zones,caching:primary or secondary`. • Separate multiple include or exclude entries with commas. For example, `finance,sales:corp00,HQ`. • If you are specifying only include criteria, the colon is not necessary. For example, `primary DNS domain`. • If you are specifying only exclude criteria, start the search string with a colon. For example, `:online help`.
Maximum number of entries per event	Specify the maximum number of log entries to be included in each event's detail message. If this script finds more entries in the log than the specified maximum, the script will return multiple events to report the number of entries you have specified. The default is 30 entries.
Event severity when matching Fax service log entries found	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the event log contains entries that match your search criteria. The default is 8 (red event indicator).

83.24 FaxServiceDown

Use this Knowledge Script to monitor the status of the Microsoft Fax service. This script raises an event if the service is down. You can set this script to automatically attempt to restart the service when it is not running.

83.24.1 Resource Object

Fax service object

83.24.2 Default Schedule

The default interval for this script is **Every 30 minutes**.

83.24.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if Fax service is down?	Set to **y** to raise an event when the Microsoft fax service is down. The default is y.
Collect data?	Set to **y** to collect data for charts and reports. If enabled, data collection returns a value of 100 if the service is running, and a value of 0 if the service is not running. The default is n.
Automatically restart service if down?	Set to **y** to automatically restart the service when it is down. The default is y.
Event severity when auto-start fails	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the service is down and AppManager cannot restart it. The default is 5 (red event indicator).
Event severity when auto-start succeeds	Set the event severity level, from 1 to 40, to indicate the importance of an event in the service was down and AppManager successfully restarted it. The default is 25 (blue event indicator).
Event severity when service down and auto-start disabled	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the service is down and AppManager has been set to not restart the service. The default is 18 (yellow event indicator).

83.25 FaxTotalFailed

Use this Knowledge Script to monitor the total number of failed faxes, failed outgoing connections, and failed receptions. This script raises an event if the number of failed faxes, failed outgoing connections, or failed receptions exceeds the threshold you set.

83.25.1 Resource Object

Fax folder

83.25.2 Default Schedule

The default interval for this script is **Every 15 minutes**.

83.25.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if number of failed faxes exceeds threshold?	Set to **y** to raise an event if the number of failed faxes exceeds the threshold you set. The default is y.
Raise event if number of failed receptions exceeds threshold?	Set to **y** to raise an event if the number of failed fax receptions exceeds the threshold you set. The default is y.
Raise event if number of failed outgoing connections exceeds threshold?	Set to **y** to raise an event if the number of failed outgoing fax connections exceeds the threshold you set. The default is y.
Threshold – Maximum number of failed faxes	Specify the maximum number of faxes that can fail to connect or be received before an event is raised. The default is 200 faxes.
Threshold – Maximum number of failed receptions	Specify the maximum number of faxes that can fail to be received before an event is raised. The default is 20 faxes.
Threshold – Maximum number of failed outgoing connections	Specify the maximum number of faxes that can fail to make an outgoing connection before an event is raised. The default is 20 faxes.
Collect data for number of failed faxes?	Set to y to collect data for charts and reports. When enabled, data collection returns the number of faxes that failed to connect or be received during the monitoring interval. The default is n.
Collect data for number of failed receptions?	Set to y to collect data for charts and reports. When enabled, data collection returns the number of faxes that failed to be received during the monitoring interval. The default is n.
Collect data for number of failed outgoing connections?	Set to y to collect data for charts and reports. When enabled, data collection returns the number of faxes that failed to make an outgoing connection during the monitoring interval. The default is n.
Event severity when threshold exceeded	Set the event severity level, from 1 to 40, to indicate the importance of an event in which a threshold is exceeded. The default is 8 (red event indicator).

83.26 FaxTotalTime

Use this Knowledge Script to monitor the number of minutes the Microsoft Fax service spends receiving faxes, the number of minutes the service spends sending faxes, and the total number of minutes the service spends receiving and sending faxes. This script raises an event if any of these values exceeds the threshold you set.

83.26.1 Resource Object

Fax folder

83.26.2 Default Schedule

The default interval for this script is **Every 5 minutes**.

83.26.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if minutes spent receiving faxes exceeds threshold?	Set to **y** to raise an event when the number of minutes the fax service spent receiving faxes exceeds the threshold you set. The default is y.
Raise event if minutes spent sending faxes exceeds threshold?	Set to **y** to raise an event when the number of minutes the fax service spent sending faxes exceeds the threshold you set. The default is y.
Raise event if total minutes spent sending and receiving faxes exceeds threshold?	Set to **y** to raise an event when the total number of minutes the fax service spent sending and receiving faxes exceeds the threshold you set. The default is y.
Threshold – Maximum minutes spent receiving faxes	Specify the maximum number of minutes that the fax service can spend receiving faxes before an event is raised. The default is 20000 minutes.
Threshold – Maximum minutes spent sending faxes	Specify the maximum number of minutes that the fax service can spend sending faxes before an event is raised. The default is 20000 minutes.
Threshold – Maximum total minutes spent receiving and sending faxes	Specify the maximum number of minutes that the fax service can spend sending and receiving faxes before an event is raised. The default is 20000 minutes.
Collect data for minutes spent receiving faxes?	Set to **y** to collect data for charts and reports. If enabled, data collection returns the number of minutes the fax service spent receiving faxes during the monitoring period. The default is n.
Collect data for minutes spent sending faxes?	Set to **y** to collect data for charts and reports. If enabled, data collection returns the number of minutes the fax service spent sending faxes during the monitoring period. The default is n.

Parameter	How to Set It
Collect data for total minutes spent receiving and sending faxes?	Set to **y** to collect data for charts and reports. If enabled, data collection returns the number of minutes the fax service spent sending and receiving faxes during the monitoring period. The default is n.
Event severity when any threshold exceeded	Set the event severity level, from 1 to 40, to indicate the importance of an event in which a threshold is exceeded. The default is 8 (red event indicator).

83.27 OpenSystemSlots

Use this Knowledge Script to monitor the number of available system (PCI) slots. This script raises an event if the number of available system slots falls below the threshold you set.

PCI (Peripheral Component Interconnect) slots allow different types of expansion cards to be connected inside a computer to extend the computer's functionality. Examples of PCI expansion cards are network cards, graphics cards, and sound cards.

83.27.1 Resource Objects

Windows 2003 Server or later

83.27.2 Default Schedule

The default interval for this script is **Every 24 hours**.

83.27.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if available system slots fall below threshold?	Set to **y** to raise an event when the number of available system slots falls below the threshold you set. The default is y.
Collect data for number of available system slots?	Set to **y** to collect data for charts and reports. If enabled, data collection returns the number of system slots that were available during the monitoring period. The default is n.
Threshold – Minimum number of available system slots	Specify minimum number of system slots that must be available to prevent an event from being raised. The default is 1 slot.
Event severity when available system slots fall below threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of available system slots falls below the threshold. The default is 5 (red event indicator).

83.28 PNPDeviceChange

Use this Knowledge Script to monitor the plug-and-play device list for any device that has been added or removed since the script was last run. This script raises an event if plug-and-play devices (for example, an external modem) are added or removed.

83.28.1 Resource Objects

Windows 2003 Server or later

83.28.2 Default Schedule

The default interval for this script is **Every 24 hours**.

83.28.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if plug and play devices added or removed?	Set to **y** to raise an event when a plug-and-play device is added to or removed from the device list. The default is y.
Collect data for devices added or removed?	Set to **y** to collect data for charts and reports. If enabled, data collection returns the contents of the device list. The default is n.
Event severity when devices added or removed	Set the event severity level, from 1 to 40, to indicate the importance of an event in which a plug-and-play device is added or removed from the device list. The default is 5 (red event indicator).

83.29 PNPDeviceErrors

Use this Knowledge Script to monitor the number of plug-and-play devices that have a status of "error." This script raises an event if the number of plug-and-play devices with error status exceeds the threshold.

83.29.1 Resource Objects

Windows 2003 Server or later

83.29.2 Default Schedule

The default interval for this script is **Every 24 hours**.

83.29.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to set it
Raise event if plug and play devices with error status exceed threshold?	Set to **y** to raise an event when the number of devices with a status of "error" exceeds the threshold you set. The default is y.
Collect data for number of devices with error status?	Set to **y** to collect data for charts and reports. If enabled, data collection returns the number of devices that have the status of "error." The default is n.
Threshold – Maximum number of plug and play devices with error status	Specify the maximum number of devices that can have an "error" status before an event is raised. The default is 10 devices.
Event severity when devices with error status exceed threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of devices with "error" status exceeds the threshold. The default is 5 (red event indicator).

83.30 PrinterStuckJobs

Use this Knowledge Script to monitor jobs that are stuck in the printer queue. This script raises an event if the number of minutes a job has remained in the printer queue exceeds the threshold you set.

83.30.1 Resource Objects

Printer folder

Printer object

83.30.2 Default Schedule

The default interval for this script is **Every hour**.

83.30.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if time in printer queue exceeds threshold?	Set to **y** to raise an event when the number of minutes a job spends in the printer queue exceeds the threshold you set. The default is y.
Collect data for time spent in printer queue?	Set to **y** to collect data for charts and reports. If enabled, data collection returns the number of minutes a job spent in the printer queue. The default is n.
Threshold – Maximum time spent in printer queue	Specify the maximum number of minutes a job can spend in the printer queue before an event is raised. The default is 5 minutes.
Event severity when time in printer queue exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of minutes a job spends in the printer queue exceeds the threshold. The default is 1 (red event indicator).

83.31 SRDiskPercent

Use this Knowledge Script to monitor the percentage of space on a disk available for the System Restore service. The System Restore service configuration for the percentage of space available (by default this value is 12%) applies to all the computer's drives. If you enter a lower value for the threshold, this script raises an event, because the percentage of disk space available for the System Restore Service, as configured, exceeds the threshold you set.

If the amount of free disk space on a system drive falls below 200 MB, or if the amount of free disk space on a non-system drive falls below 80 MB, it is advisable to configure System Restore to turn off automatically on that drive. This script also raises an event if the space available for System Restore on any system or non-system drive falls below the threshold you set.

83.31.1 Resource Object

System Restore folder

83.31.2 Default Schedule

The default interval for this script is **Run once**.

83.31.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if percentage of disk space exceeds threshold?	Set to **y** to raise an event when the percentage of disk space configured for System Restore exceeds the threshold. The event detail message will include the disk space available for System Restore for each individual drive. The default is y.
Raise event if space available on a drive falls below threshold?	Set to **y** to raise an event when the space available for System Restore on any system or non-system drive falls below the threshold. The default is n.
Collect data for percentage of disk space being used?	Set to **y** to collect data for charts and reports. If enabled, data collection returns the percentage of disk space that is configured for System Restore. The default is n.
Collect data for space available on individual drive	Set to **y** to collect data for charts and reports. If enabled, data collection returns the space available for System Restore on any system or non-system drive. The default is n.
Threshold – Maximum disk space configured for System Restore	Specify the maximum percentage of disk space that can be configured for System Restore before an event is raised. The default is 12%.
Threshold – Minimum disk space available on system drive	Specify the minimum amount of disk space (in MB) that should be available for System Restore on a system drive to prevent an event from being raised. The default is 200 MB.
Threshold – Minimum disk space available on non-system drive	Specify the minimum amount of disk space (in MB) that should be available for System Restore on a non-system drive to prevent an event from being raised. The default is 80 MB.

Parameter	How to Set It
Event severity when disk space available cannot be retrieved	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the amount of available disk space cannot be determined. The default is 8.
Event severity when disk space configured for System Restore exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the amount of configured disk space exceeds the threshold. The default is 8.
Event severity when space available on individual drive falls below threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the amount of available disk space for an individual drive falls below the threshold. The default is 5.

83.32 SREventLog

Use this Knowledge Script to periodically scan the Windows Application event log for entries created by the System Restore service that match the criteria you specify. This script raises an event if an entry matches criteria you specify. The event detail message provides more information about the event.

In the first interval, the value you specify for the *Start with events in past N hours* parameter determines how far back in the log to check for matching entries. As the script continues to run at subsequent intervals, it checks for any new entries created since the last time the log was checked.

You can further restrict the types of log entries that generate an event in two ways:

- Use the *Monitor for events of type [...]* parameters to search only certain types of events, such as Warning events.
- Use the *Filter the [...] field for* parameters to search only for specific information, such as events associated with a specific user or computer name.

Each time this script runs, it checks the Windows Application event log for entries matching your selection criteria and raises an event if matching entries are found. The event detail message returns the text of the log entries found. When this script is set to collect data, it returns the number of log entries found, and the data point detail message returns the text of the log entries.

83.32.1 Resource Object

System Restore folder

83.32.2 Default Schedule

The default interval for this script is **Every 30 minutes**.

83.32.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if matching log entries found?	Set to **y** to raise an event when the log contains entries that match your search criteria. The default is y.
Collect data for matching log entries found?	Set to **y** to collect data for charts and reports. If enabled, data collection returns the number of log entries found. The data point detail message returns the text of the log entries. The default is n.
Start with events in past N hours	Set this parameter to determine which part of the log to search the first time the job runs. Subsequent searches begin where the previous one finished. The following entries are valid: • **-1** to search all existing log entries during the first interval • **n** to search entries for the past *n* hours (8 for the past 8 hours, 50 for the past 50 hours, for example.) • **0** to search no previous entries (search from the current time forward) The default is 0.

Parameter	How to Set It
Monitor for events of type:	Set to **y** for each type of event you want to monitor: • Error • Warning • Information • Success Audit • Failure Audit If you disable any of these event types, that type of log entry does not raise an event, is not returned in an event detail message, and is not collected as data if you enabled *Collect data for matching log entries found?* The default is y.
Filter the [...] field for	To limit the types of entries that raise events and the type of data that is collected, enter a search string that filters the following fields in the event log: • **Category**. Specify one or more text strings to look for in the Category field. Separate multiple strings with commas. • **Event ID**. Specify single or multiple event IDs. Separate multiple entries with commas. To specify a range of event IDs, use a hyphen. For example: `414,1028-1400,4015`. • **User**. Specify a single or multiple user names to look for. Separate multiple entries by commas. For example: `Pat,Chris,Alex`. • **Computer**. Specify a single or multiple computer names or IP addresses to look for. Separate multiple entries by commas. For example: `SHASTA,MARS`. • **Event Description**. Specify a detail description or keywords in the description. The string can contain spaces, underscores, and periods. Separate multiple entries with commas. For example: `no domain,critical error from the Active Directory`. The search string can contain criteria used to include entries, exclude entries, or both. • Separate the include and exclude criteria with a colon (:). For example, `zones,caching:primary or secondary`. • Separate multiple include or exclude entries with commas. For example, `finance,sales:corp00,HQ`. • If you are specifying only include criteria, the colon is not necessary. For example, `primary DNS domain`. • If you are specifying only exclude criteria, start the search string with a colon. For example, `:online help`.
Maximum number of entries per event message	Specify the maximum number of log entries to be included in each event's detail message. If this script finds more entries in the log than the specified maximum, it will return multiple events to report the number of entries you have specified. The default is 30 entries.
Event severity when matching entries found	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the log contains entries that match your search criteria. The default is 8 (red event indicator).

83.33 SRLifeInterval

Use this Knowledge Script to monitor the number of days the System Restore service preserves System Restore points.

A *restore point* is a snapshot of the system provided by the System Restore service. For example, when you install an application on your computer, a restore point is created and stored in the database. If you later want to return to the registry as it was configured before you installed the new application, select the restore point in the System Restore utility that represents your system configuration prior to installation. Your system is restored to its state before the new application was installed.

This script raises an event if the number of days that restore points have been preserved exceeds the threshold.

83.33.1 Resource Object

System Restore folder

83.33.2 Default Schedule

The default interval for this script is **Every 24 hours**.

83.33.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if restore point lifetime exceeds threshold?	Set to **y** to raise an event when the number of days a restore point has been preserved exceeds the threshold you set. The default is y.
Collect data for length of restore point lifetime?	Set to **y** to collect data for charts and reports. If enabled, data collection returns the number of days a restore point has been preserved. The default is n.
Maximum number of restore points to include in event	Specify the number of restore points to display in the event detail message. A full list of restore points can be viewed at `$(INSTALLPATH)\LifeSrPtsLog`. Restore points are displayed in order of creation date, the most recent first. The default is 20 restore points. Set to 0 to display all restore points in the event detail message.
Threshold – Maximum restore point lifetime	Specify the maximum number of days restore points can be preserved before an event is raised. The default is 4 days.
Event severity when restore point lifetime exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of days restore points are preserved exceeds the threshold. The default is 8 (red event indicator).

83.34 SRPoints

Use this Knowledge Script to monitor the number of System Restore points that are being preserved by the System Restore service. This script raises an event if the number of System Restore points exceeds the threshold. If the System Restore system preserves too many restore points, including many old restore points, the life interval of the restore points may be too long.

83.34.1 Resource Object

System Restore folder

83.34.2 Default Schedule

The default interval for this script is **Every 10 minutes**.

83.34.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if number of restore points exceeds threshold?	Set to **y** to raise an event when the number of restore points exceeds the threshold. The default is y.
Collect data for number of restore points?	Set to **y** to collect data for charts and reports. If enabled, data collection returns the number of restore points being preserved by the System Restore service. The default is n.
Threshold – Maximum total system restore points	Specify the maximum number of restore points that can be preserved before an event is raised. The default is 4 restore points.
Maximum number of restore points to include in event	Specify the number of restore points to display in the event detail message. A full list of restore points can be viewed at `$(INSTALLPATH)\ShortSrPtslog`. Restore points are displayed in order of creation date, the most recent first. The default is 20 restore points. Set to 0 to display all restore points in the event detail message.
Event severity when total number of restore points exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of preserved restore points exceeds the threshold. The default is 8 (red event indicator).

83.35 SRScheduledInterval

Use this Knowledge Script to monitor the interval, in hours, at which scheduled System Restore points are created during both current and global sessions. This script raises an event if the interval exceeds the threshold.

Exceeding the threshold means that System Restore points are being created less often than the threshold, not more often. For example, there may be five hours between System Restore points, rather than four (the default maximum threshold).

83.35.1 Resource Object

System Restore folder

83.35.2 Default Schedule

The default interval for this script is **Every 10 minutes**.

83.35.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if global time interval exceeds threshold?	Set to **y** to raise an event when the interval at which restore points are created exceeds the time interval for global sessions. The default is y.
Raise event if current session time interval exceeds threshold?	Set to **y** to raise an event when the interval at which restore points are created exceeds the time interval for current sessions. The default is y.
Collect data for global time interval?	Set to **y** to collect data for charts and reports. If enabled, data collection returns the restore point creation interval for global sessions. The default is n.
Collect data for current session time interval?	Set to **y** to collect data for charts and reports. If enabled, data collection returns the restore point creation interval for current sessions. The default is n.
Threshold - Maximum global time interval	Specify the maximum interval at which restore points can be created for a global session before an event is raised. The default is every 4 hours.
Threshold - Maximum current session time interval	Specify the maximum interval at which restore points can be created for a current session before an event is raised. The default is every 4 hours.
Maximum number of restore points to include in event	Specify the number of restore points to display in the detail message.These restore points will have the description "System Check Point." A full list of restore points can be viewed at `$(INSTALLPATH)]\SysChkLog`. Restore points are displayed in order of creation date, the most recent first. The default is 20 restore points. Set to 0 to display all restore points in the event detail message.
Event severity when global time interval exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the restore point creation interval for global sessions exceeds the threshold. The default is 8 (red event indicator).

Parameter	How to Set It
Event severity when current session time interval exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the restore point creation interval for current sessions exceeds the threshold. The default is 8 (red event indicator).

83.36 SRServiceDown

Use this Knowledge Script to monitor the status of the System Restore service. This script raises an event if the service is down. You can set this script to automatically attempt to restart the service when it is not running.

83.36.1 Resource Object

System Restore Service object

83.36.2 Default Schedule

The default interval for this script is **Every 30 minutes**.

83.36.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if System Restore service is down?	Set to **y** to raise an event when the System Restore service is down. The default is y.
Collect data for System Restore service status?	Set to **y** to collect data for charts and reports. If enabled, data collection returns: • 100 – service is running, or • 0 – service is not running. The default is n.
Auto-start service if down?	Set to **y** to automatically restart the service when it is down. The default is y.
Event severity when auto-start fails	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the service is down and AppManager cannot restart it. The default is 5 (red event indicator).
Event severity when auto-start succeeds	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the service was down and AppManager successfully restarted it. The default is 25 (blue event indicator).
Event severity when service down and auto-start disabled	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the service is down and AppManager has been set to not restart the service. The default is 18 (yellow event indicator).

84 Windows-RT Knowledge Scripts

The Windows-RT category provides the following Knowledge Scripts you can use with AppManager. From the Knowledge Script view of Control Center, you can access more information about any NetIQ-supported Knowledge Script by selecting it and clicking **Help**. In the Operator Console, click any Knowledge Script in the Knowledge Script pane and press `F1`.

Knowledge Script	What It Does
ChangeLocking	Lets you turn on or off the locking of a workstation so you can control access to that workstation.
ClosePlayer	Lets you shut down the Player that runs a script made by the Windows-RT Designer, such as when a running script is not working properly or a process is looping incorrectly.
TakeDesktopOwnership	Updates the Registry key indicating ownership of the desktop so that Windows-RT can run on the specified computer.

84.1 ChangeLocking

The ChangeLocking Knowledge Script allows you to turn on or off the locking of the keyboard and mouse used by a computer during the playback of a script. By default, when the Player executes a Windows-RT script on a system, Windows-RT locks all input from the mouse and keyboard for that system.

You can also change the default setting for the `InputLockOnStartup` setting in the `NetIQ.AppMan.WinRT7.Player.exe.config` file, located in the `NetIQ\AppManager\bin\Win-RT7\Player` directory.

84.1.1 Resource Object

WinRT7 Folder

84.1.2 Default Schedule

By default, this script runs once.

84.1.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How To Set It
General Settings	
Enable the ability to lock mouse and keyboard input?	Select this check box to prevent input from the mouse and keyboard of the specified computer during script playback.
Raise event if the locking of the mouse and keyboard input has been successful?	Select this check box to raise an event when the input locking has been successful. The default is selected.
Event severity when the locking of the mouse and keyboard inputs has been completed successfully	Specify a severity level, from 1 to 40, to indicate the importance of the event related to discovery. Default is 35.

84.2 ClosePlayer

The ClosePlayer Knowledge Script lets you shut down the Player that runs a script made by the Windows-RT Designer.

84.2.1 Resource Object

WinRT7 Folder

84.2.2 Default Schedule

By default, this script runs once.

84.2.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How To Set It
General Settings	
Raise event if player closed successfully?	Select this check box to raise an event when the script player closes successfully. The default is selected.
Event severity when player closed successfully	Specify a severity level, from 1 to 40, to indicate the importance of the event in which the script player closes. The default is 35.

84.3 TakeDesktopOwnership

Use this Knowledge Script to check and update the shared registry value used to indicate which ResponseTime module is permitted to run its associated Knowledge Scripts.

This script attempts to update the `Desktop` registry value (located under the `HKEY_LOCAL_MACHINE\SOFTWARE\NetIQ\Response Time` Registry key) to indicate that Windows-RT Knowledge Scripts are allowed to run. For more information, see .

Important Because this script does not contain an embedded Windows-RT script, you cannot modify it using the Windows-RT Designer.

84.3.1 Resource Object

WinRT7 Folder

84.3.2 Default Schedule

By default, this script runs once.

84.3.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How To Set It
General Settings	
Job Failure Notification	
Event severity when take desktop ownership fails?	Set the event severity level, from 1 to 40, to indicate the importance of an event in which an error prevents the script from setting the Registry value to indicate that Windows-RT has ownership of the desktop. The default is 5.
Raise event if take desktop ownership successful?	Select **Yes** to raise an event when the script updates the Registry value to indicate that Windows-RT has ownership of the desktop. The default is unselected.
Event severity when take desktop ownership successful?	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the script updates the Registry value indicating Windows-RT has ownership of the desktop. The default is 35.

85 WMI Knowledge Scripts

AppManager provides the following Knowledge Scripts for monitoring Microsoft Windows Management Instrumentation (WMI) services and executing WMI queries.

From the Knowledge Script view of the Control Center, you can access more information about any Knowledge Script by selecting it and clicking **Help**. In the Operator Console, click any Knowledge Script in the Knowledge Script pane and press **F1.**

Knowledge Script	What It Does
Configure	Configures the frequency of the WMI repository backup and the type, size, and location of the logging files.
EventConsumer	Monitors for events generated by the WMI event provider and allows you to search for events in the database.
LogSizes	Monitors the size of WMI log files.
RepositoryUsage	Monitors the size of the WMI repository.
ResourceHigh	Monitors the CPU and memory consumption for WMI processes.
RunWQL	Allows you to run WQL statements.
ServiceDown	Monitors the availability of the WMI CIMOM service.
UserManager	Allows you to add, delete, or edit a WMI user account or WMI group account for the WMI service.

85.1 Configure

Use this Knowledge Script to configure the frequency of the WMI repository backup and the type, size, and location of the logging files.

NOTE: This Knowledge Script is not supported for WMI servers running Windows Server 2012, Windows 8, Windows Server 2008 R2, Windows Server 2008, Windows Vista, or Windows 7.

85.1.1 Resource Object

WMI server

85.1.2 Default Schedule

The default schedule for this script is **Run once**.

85.1.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Raise event if operation succeeds?	Set to **y** to raise an event when the selected operation succeeds. The default is **y**. **NOTE:** This script always raises an event if a selected operation fails.
Time between repository backup attempts	Enter the number of minutes between WMI backup repository attempts. The default is 60 minutes.
Logging type: disable(d)/error(e)/verbose(v)	Specify the type of log files you want created by the WMI repository backup operation. Valid values are: • **d** to disable logging (no log file is created) • **e** to enable error logging (log file records any errors encountered) • **v** to enable verbose logging (log file includes error and informational messages) The default is **e**.
Maximum log file size	Enter the maximum size of the log file in bytes. If the log file exceeds this size, the file is truncated. The default is 65535 bytes.
Logging directory	Enter the name of the directory to use for log files.
Event severity level for...	Set the event severity level, from 1 to 40, to indicate the importance of: • **...configuration succeeded**. The default is 25 (blue event indicator). • **...configuration failed**. The default is 5 (red event indicator).

85.2 EventConsumer

Use this Knowledge Script to search a specific WMI repository namespace for events generated by the event provider. Enter the search criteria using the Windows Management Instrumentation Query Language (WQL). You can perform event queries with this script using the `SELECT` statement and related `WITHIN`, `GROUP`, and `HAVING` clauses. For more information about WQL, refer to the Microsoft documentation.

This script raises an event when events matching your query are found in the WMI repository. You specify the WMI event properties to display in the AppManager event.

85.2.1 Resource Object

WMI server

85.2.2 Default Schedule

The default schedule for this script is **Asynchronous**. This script will run indefinitely until you stop the script.

85.2.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Path to the WMI namespace	Specify the path to the WMI namespace you want to monitor. The default is `root\cimv2`.
WMI event query	Specify the information you want to find in the WMI repository using the WQL query format. The default query is: `select * from __InstanceCreationEvent within 1 where TargetInstance is a 'Win32_NTLogEvent'`
Fields to display for the event in the List pane	Specify the type of event information to display in the Message field in the List pane of the Operator Console. By default, the Source Name and Event ID fields are displayed. For example, if the source of an event is `MSSQLSERVER` and the Event ID is `17055`, the information displayed in the Message field would be `MSSQLSERVER - 17055`. **NOTE:** This parameter requires case-sensitive entries. For example, do not enter `sourcename` if the actual field name is `SourceName`.
Event severity level	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 5 (red event indicator).

85.3 LogSizes

Use this Knowledge Script to monitor the size of the following WMI log files:

- cimom.log
- mofcomp.log
- wbemcore.log
- wbemprox.log

This Knowledge Script allows you to set a maximum log file size for individual log files and a maximum size for the sum of all log files. If either threshold is exceeded, an event is raised.

NOTE: This Knowledge Script is not supported for WMI servers running Windows Server 2012, Windows 8, Windows Server 2008 R2, Windows Server 2008, Windows Vista, or Windows 7.

85.3.1 Resource Object

WMI Log file object

85.3.2 Default Schedule

The default interval for this script is **Once every hour**.

85.3.3 Setting Parameter Values

Set the following parameters as needed:

Parameter	How to Set It
Event?	Set to **y** to raise events. The default is **y**.
Collect data for all log files?	Set to **y** to collect data for all log files. If set to **y**, the script returns the total file size used by all log files. The default is **n**.
Collect data for individual log files?	Set to **y** to collect data for individual log files. If set to **y**, the script returns the file size used by each log file. The default is **n**.
All log files size maximum threshold	Enter a threshold in MB for the maximum total file size used by all log files. The default is 1000 MB.
Individual log files size maximum threshold	Enter a threshold in MB for the maximum size of each log file. The default is 50 MB.
Event severity level	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 5 (red event indicator).

85.4 RepositoryUsage

Use this Knowledge Script to monitor the size of the WMI repository. If the repository size exceeds the threshold you set, an event is raised.

85.4.1 Resource Object

WMI Repository folder

85.4.2 Default Schedule

The default interval for this script is **Once every hour**.

85.4.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default is **y**.
Collect data?	Set to **y** to collect data for graphs and reports. If set to **y**, the script returns the size of the WMI repository in MB. The default is **n**.
Repository size	Enter a threshold in MB for the repository size. The default is 500 MB.
Event severity level	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 5 (red event indicator).

85.5 ResourceHigh

Use this Knowledge Script to monitor CPU and memory consumption by the WMI service (`Winmgmt`). This script raises an event if CPU usage or memory usage exceeds the threshold you set.

NOTE: The `Winmgmt` service runs with several other services under an instance of the `svchost.exe` process. Therefore, when the ResourceHigh Knowledge Script monitors CPU and memory for the `Winmgmt` service, it is actually monitoring these same metrics for all services hosted by the instance of the `svchost.exe` process.

If you set the *Collect data?* parameter to **y**, the values returned for percentage of CPU used and MB of memory used are sums of CPU usage and memory usage for all services hosted by the `svchost.exe` process. The values do not represent CPU and memory usage for only the `Winmgmt` service.

85.5.1 Resource Object

WMI server

85.5.2 Default Schedule

The default interval for this script is **Every 10 minutes**.

85.5.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default is **y**.
Collect data?	Set to **y** to collect data for graphs and reports. If set to **y**, the script returns the percentage of CPU resources and the MB of memory used by the WMI service. The default is **n**.
% CPU maximum threshold	Enter a threshold for the maximum percentage of CPU resources that WMI should be allowed to consume. The default is 60%.
Memory maximum threshold (in MB)	Enter a threshold in MB for the maximum amount of memory WMI should be allowed to consume. The default is 6 MB.
Event severity level	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 8 (red event indicator).

85.6 RunWQL

Use this Knowledge Script to run WMI Query Language (WQL) queries. You can enter the WQL query to be executed as a parameter of this Knowledge Script, or you can load the query from a script file. You can choose the data output to be a specified number of data rows (all columns) or the value of the first row of a specific column (the column is specified by either number or name).

Examples of simple WQL queries:

```
/* Command to get the path setting for a computer. */
Select * from Environment where Name = âĂŹPathâĂŹ

/* Command to get information about the provider CIMWin32. */
Select * from _Win32Provider where Name = âĂŹCIMWin32âĂŹ
```

85.6.1 Resource Object

WMI server

85.6.2 Default Schedule

The default interval for this script is **Run once**.

85.6.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Event?	Set to **y** to raise events. The default is **y**.
Collect data?	Set to **y** to collect data for graphs and reports. The default is **y**.
WQL query	Enter the WQL query that will run. The default query is: `SELECT Caption, ThreadCount FROM win32_Process` **Tip** Unless you are entering very simple queries, you may find that typing WQL statements in this field is error-prone. To avoid errors, you can use the *Load WQL script from file* parameter. Alternatively, if you have an AppManager Developer's license, you can check this Knowledge Script out of the repository, use the Knowledge Script Editor to paste the desired WQL statements into the WQL query field, and then check in the modified Knowledge Script.
Load WQL script from file?	Set to **y** to load an existing WQL script. The file containing the script must be present on the computer on which the Knowledge Script job will run. The default is **n**.
WQL script file (full path)	Enter the full path to the file that contains the WQL script (for example: `C:\netiq\Sample.wql`). **NOTE:** This path is relative to the computer on which the Knowledge Script job will run.
WMI server\namespace	Enter the name of the managed WMI server and CIM namespace. The default is `root\CIMv2`.

Description	How to Set It
Return N rows (set to 0 for all rows)	Enter the number of rows to return as data output when the *Collect data?* parameter is set to **y**. The default is 10. **NOTE:** You can set this value to 0 to set no limit on the number of rows returned. However, there is a limit of 32K for the total of returned data.
Return first row of specified column?	Set to **y** to use a specified column number or column name from which data will be returned (specify the column number or name in one of the two following parameters). Setting this parameter to **y** will override the *Return N rows* parameter. The default is **n**.
Column number	If the *Return first row of specified column?* parameter is set to **y**, the value of the first row of the column specified here (by number), rather than the number of rows, is used as data output. The default is 0.
Column name	If the *Return first row of specified column?* parameter is set to **y**, the value of the first row of the column specified here (by name), rather than the number of rows, is used as data output. The default is blank.
GivenLegend	String used in the Legend column of graph data. If this value is left blank, the Legend column will read: “WQL query results on WMI Server: <machine name>.”
Maximum threshold	Set the high watermark for the return value of the WQL query (this value can be the number of rows returned or the value of the first row of a specified column, depending on the type of data output you chose). If the return value exceeds this limit, an event will be raised. The default is 10000.
Minimum threshold	Set a low watermark for the return value of the WQL query (this value can be the number of rows returned or the value of the first row of a specified column, depending on the type of data output you chose). If the return value is below this limit, an event will be raised. The default is 10.
Event severity level	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 5 (red event indicator).

85.7 ServiceDown

Use this Knowledge Script to monitor the WMI CIMOM (Common Information Model Object Manager) service. If the CIMOM service is not running, an event is raised. Optionally, you can set the Knowledge Script to attempt to restart the service automatically.

85.7.1 Resource Object

WMI service object

85.7.2 Default Schedule

The default interval for this script is **Every 5 minutes**.

85.7.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Collect data?	Set to **y** to collect data for graphs and reports. The default is **n**. If set to **y**, the script returns a value of 100 if the CIMOM service is running and a value of 0 if the service is not running.
Auto-start service?	Set to **y** to automatically restart down services. The default is **y**.
Event severity level for...	Set the event severity level, from 1 to 40, to indicate the importance of: • **...service down; restart failed**. The default is 5 (red event indicator). • **...service down; restart succeeded**. The default is 25 (blue event indicator). • **...service down; don't restart**. The default is 18 (yellow event indicator).

85.8 UserManager

Use this Knowledge Script to add, delete, or edit WMI user or group accounts for the WMI service on the computer where the Knowledge Script job is running. You can also use this Knowledge Script to manage user access to CIM objects.

This script can add or modify domain accounts or groups. The account or group you are modifying must belong to the same domain as the computer on which the script is running.

By default, this script raises an event whose message informs you of the success or failure of the operation.

If you want to use this script to manage an account that was added from the WMI Control, that account must meet the following requirements:

- Permissions must be granted for **This namespace and subnamespaces**.
- Permissions must allow Provider Write, Enable Account, and Remote Enable.

NOTE: This Knowledge Script is not supported for WMI servers running Windows Server 2012, Windows 8, Windows Server 2008 R2, Windows Server 2008, Windows Vista, or Windows 7.

85.8.1 Resource Object

WMI server

85.8.2 Default Schedule

The default interval for this script is **Run once**.

85.8.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Raise event if operation succeeds?	Set to **y** to raise an event when the selected operation succeeds. The default is **y**. **NOTE:** This script always raises an event if a selected operation fails.
Manage user or group?	Set to **u** to manage user accounts. Set to **g** to manage group accounts. The default is **u**.
Operation to perform: add(a)/delete(d)/edit(e)	Indicate the type of operation you want to perform. Set to one of the following: • **a** to Add users or groups • **d** to Delete users or groups • **e** to Edit users or groups The default is **a**.
User or Group names to be managed	Enter the user or group account name you want to manage. You can enter multiple names, separated by commas with no spaces. For example: `guest,admin,user1` The default is guest.

Description	How to Set It
Domain name	Enter the domain name associated with the user or group account. You must specify the local machine name when deleting or editing a local user.
Enable this account?	Set to **y** to enable the specified accounts if you are adding new user or group accounts or editing existing accounts. Set to **n** to disable an account. The default is **y**.
Can this account execute methods?	Set to **y** to give the specified accounts permission to execute methods exported from the CIM Object Manager. The default is **n**.
Schema access privileges: Read-only(r) / Write instance(i) / Write class(c)?	Indicate the WMI schema access allowed for the specified accounts. Set to: • **r** to authorize read-only access (users can execute queries or retrieve instances and classes, but cannot create, delete, or modify CIM objects). • **i** to allow the account read/write/delete access to instances in the WMI schema and read-only access to classes. • **c** to allow the account full read/write/delete access to all CIM objects, classes, and instances in the WMI schema. The default is **r**.
Can this account edit security?	Set to **y** to give the specified accounts permission to edit security. When set to **y**, the user has read and write access to the ROOT\Security namespace. When set to **n**, the user cannot access the ROOT\Security namespace. The default is **n**.
Group account type: NTLM Local(l)/NTLM Global(g)	Indicate whether the specified group accounts are local to the managed computer or global. Set to: • **l** to create a local Windows group (that can only access the local workstation or domain). • **g** to create a domain global group (that can access its own domain, member servers and workstations in the domain, and trusting domains). This parameter is used only for managing group accounts. The default is **l**.
Event severity level	Set the severity level, from 1 to 40, to indicate the importance of the event. The default is 12 (yellow event indicator).

86 WTS Knowledge Scripts

AppManager provides the following Knowledge Scripts for monitoring Windows Terminal Server (WTS) application resources.

From the Knowledge Script view of Control Center, you can access more information about any NetIQ-supported Knowledge Script by selecting it and clicking **Help**. In the Operator Console, click any Knowledge Script in the Knowledge Script pane and press **F1**.

Knowledge Script	What It Does
LoggedOffSessions	Collects data about completed WTS sessions.
Messenger	Sends a message to a user currently connected to a WTS session.
SessionsInfo	Reports information about the current terminal sessions connected to the terminal server.
SessionsLogoff	Terminates a WTS session.
SessionsReset	Resets a client session on a terminal server.
SessionsTimeout	Monitors the current number of WTS sessions that have timed out.
SessionsTotalActive	Monitors the current number of sessions that are currently logged onto the terminal server.
SessionsTotalBytes	Monitors the total number of input and output bytes used in a WTS session.
SessionsTotalDisconnected	Monitors the total number of sessions disconnected on a terminal server.
SessionsTotalErrors	Monitors the total number of WTS session errors.
SessionsTotalFrames	Monitors the total number of frames (packets) transmitted in a WTS session.
SessionsTotalInactive	Monitors the number of inactive WTS sessions.
SessionsTotalProtocolHitRatio	Monitors the overall hit ratio for all protocol objects per WTS session.
TopCpuProcs	Monitors CPU usage for all WTS processes and the CPU used by each of a specified number of processes.
TopCPUSessions	Monitors CPU usage for all WTS sessions and the CPU usage used by each of a specified number of sessions.
TopMemorySessions	Monitors total memory usage for all sessions and the memory used by each of the top n number of sessions.
UsersInfo	Displays information about the users currently logged on to the terminal server.

86.1 LoggedOffSessions

This Knowledge Script collects data about the completed sessions hosted by a Windows Terminal Server.

This Knowledge Script scans all user sessions and makes a note of a user's name, session ID, and logon time. On subsequent scans, it compares the current user sessions with its notes from previous sessions.

For each user that is no longer logged on, the Knowledge Script returns the user name, the session ID, the logon time, and the current time, which is the time when the Knowledge Script ran and detected that the session has ended. The script also calculates a maximum session duration by subtracting the logon time from the current time. You can set a threshold for the maximum number of sessions that can end in any interval.

The accuracy of the data returned by this Knowledge Script improves depending on how frequently you set it to run:

- The Knowledge Script cannot detect sessions that start and end *between* the intervals when it runs. For example, if you schedule the script to run every hour, a session that starts at 10:15 and ends at 10:45 will not be detected by the script when it runs at 10:00 and 11:00.
- The maximum duration is calculated using the time when the script runs and determining that a previous session is no longer active. If, for example, the script runs at 30-minute intervals and a session ends 1 minute after the script runs, 29 minutes elapse until the next time the script runs, and the maximum duration is 29 minutes longer than the actual session time.

In both cases, the accuracy of the data returned improves substantially when you schedule it to run at every minute.

TIP: One common use of this Knowledge Script is to provide billing information for the use of Windows Terminal Server (WTS) services. Each data point returned by the Knowledge Script represents a complete, billable session. When using the Knowledge Script for this purpose, remember that the accuracy of the "maximum duration" returned by this script depends on how frequently you run the Knowledge Script.

86.1.1 Resource Object

WTS Sessions

86.1.2 Default Schedule

The default interval is **Every hour**.

86.1.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Raise event if number of completed user sessions exceeds the threshold?	Set to **y** to raise an event if the number of completed user sessions exceeds the threshold you specify. The default is y.

Description	How to Set It
Collect data for completed user sessions?	Set to **y** to collect data for charts and reports. If set to y, the Knowledge Script returns the user name, the session ID, the logon time, the current time (the time when the Knowledge Script ran and detected that the session ended), and the maximum session duration (the current time minus the logon time). The default is y.
Threshold – completed user sessions	Specify the maximum number of user sessions that can end in any given interval before an event is raised. The default is 0.
Event severity when number of completed user sessions exceeds the threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event in which the number of completed user sessions exceeds the threshold. The default severity level is 8.

86.2 Messenger

This Knowledge Script sends a message to a user currently connected to a Windows Terminal Server (WTS) session.

You can specify the recipients for the message by user name, session name, session ID, or by entering a file name that contains a list of recipients by user name (user names must not include spaces), session name, or session ID.

86.2.1 Resource Object

WTS Server

86.2.2 Default Schedule

The default interval is **Run once**.

86.2.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Recipients (separate with commas)	Specify a list of recipients for the message, separated by commas with no spaces. Type an asterisk (`*`) to send a message to all sessions. The default is `*` (all sessions). You can specify WTS sessions by user name, session name, session ID, or file name. Names cannot include spaces. For example: `wsmith,jcarter,001003` If you enter a file name that contains a list of recipients, specify a complete path, including the `@` symbol. For example: `@c:\recipient.txt` **Notes** • Ensure that the list of recipients listed in the file are separated by line breaks and not special characters. • The recipient text file must contain only the list of recipients currently connected to a Windows terminal server.
Raise event if message fails to send?	Set to **y** to raise an event if the message is not successfully delivered. The default is y.
Collect data for messages sent?	Set to **y** to make the script return the number of sessions that received the message. The default is n.
Delay (time to wait for the receiver to acknowledge the message)	Specify the number of seconds to wait for the recipient to acknowledge receiving the message. After the number of seconds has passed, the message automatically closes. The default is 0 seconds, which means that the message is displayed until it the user acknowledges it.

Description	How to Set It
Message	Specify the text of the message you want to send. The default message is `work`. To avoid an error with your message, if you want to include characters in double quotes in the text of your message (such as "`Server`"), use *two* double quote characters before and after the word(s) you want to enclose. For example: ""`Server`"". The length of the text message must not exceed 246 characters.
Event severity when message fails to send	Set the event severity level, from 1 to 40, to indicate the importance of the event raised when the message is not successfully sent. The default severity level is 5.

86.3 SessionsInfo

This Knowledge Script displays information about the current terminal sessions connected to the Windows terminal server. The information returned in the detailed data message depends on the version of Windows Terminal Server (WTS):

- With some versions, the data message contains the session name, user name, session ID, current status, session type, and device.
- With other versions, the data message contains the session name, user name, session ID, current status, client address, and client name.

If the Knowledge Script cannot get information about the WTS sessions, an event is raised.

86.3.1 Resource Objects

WTS Sessions

86.3.2 Default Schedule

The default interval is **Every hour**.

86.3.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Collect data on terminal session information?	Set to **y** to collect data for charts and reports. If set to y, the script returns data on the current number of sessions connected to the target computer. The default is y.
Event severity if information cannot be retrieved	Set the event severity level, from 1 to 40, to indicate the importance of the event in which data cannot be retrieved. The default severity level is 8.

86.4 SessionsLogoff

This Knowledge Script terminates a Windows Terminal Server session. You can specify the sessions to log off by session name or session ID. If the Knowledge Script fails, an event is raised.

86.4.1 Resource Objects

WTS Sessions

86.4.2 Default Schedule

The default interval is **Run once**.

86.4.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Session Name or Session ID	Specify a list of sessions you want to terminate, separated by commas with no spaces. Type an asterisk (`*`) to terminate all sessions. Specify sessions by session name or session ID number. For example: `RDP-TCP#8,RDP-TCP#9,4.` The default is blank.
Raise event if a session cannot be logged off?	Set to **y** to raise an event if the operation fails for any reason. The default is y.
Collect data for sessions logged off?	Set to **y** to collect data for charts and reports. If set to y, the script returns the number of sessions terminated. The default is n.
Event severity when a session cannot be logged off?	Set the event severity level, from 1 to 40, to indicate the importance of the event in which a session cannot be logged off. The default severity level is 5.

86.5 SessionsReset

This Knowledge Script resets a client session on a Windows Terminal Server. When you run this Knowledge Script, the session's hardware and software subsystems are reset to the known initial values.

You can identify the session to reset by session name or session ID number. If the Knowledge Script fails, an event is raised.

86.5.1 Resource Objects

WTS Sessions

86.5.2 Default Schedule

The default interval is **Run once**.

86.5.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Session Name or Session ID	Specify a list of sessions you want to reset, separated by commas with no spaces. You can specify sessions by session name or session ID number. For example: `RDP-TCP#8,RDP-TCP#9,4`.
Raise event if session reset fails?	Set to **y** to raise events if the operation fails for any reason. The default is y.
Collect data for reset sessions?	Set to **y** to collect data for charts and reports. If set to y, the script returns the number of sessions reset. The default is n.
Event severity when reset fails	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default severity level is 5.

86.6 SessionsTimeout

This Knowledge Script to monitors the total number of timeouts on the communication line from both the host and client sides of the connection. If the number of timed-out sessions exceeds the threshold you set, an event is raised.

On some high-latency networks, the timeout could result from the protocol timeout being too short. Increasing the protocol timeout on these types of lines will improve performance by reducing unnecessary re-transmissions.

86.6.1 Resource Objects

WTS Sessions

86.6.2 Default Schedule

The default interval is **Every 30 minutes**.

86.6.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Raise event if the number of session timeouts exceeds the threshold?	Set to **y** to raise an event if the number of session timeouts exceeds the threshold you set. The default is y.
Collect data for session timeouts?	Set to **y** to collect data for charts and reports. If set to y, the script returns the total number of session timeouts. The default is y.
Threshold – maximum session timeouts per interval	Specify the number of timed-out sessions that will raise an event. The default is 0.
Event severity if the number of session timeouts exceeds the threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default severity level is 5.

86.7 SessionsTotalActive

This Knowledge Script monitors the current number of client sessions that are currently logged on to Windows Terminal Server (WTS). If the number of active sessions exceeds the threshold you set, an event is raised.

86.7.1 Resource Objects

WTS Sessions

86.7.2 Default Schedule

The default interval is **Every 1 hour**.

86.7.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Raise event if the total number of active sessions exceeds the threshold?	Set to **y** to raise an event if the total number of active sessions exceeds the threshold you set. The default is y.
Collect data for active sessions?	Set to **y** to collect data for charts and reports. If set to y, the script returns the total number of active sessions. The default is y.
Threshold – maximum active sessions	Specify the maximum number of concurrent sessions that can be active before raising an event. The default is 50.
Event severity when the total number of active sessions exceeds the threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event in which the total number of active sessions exceeds the threshold. The default severity level is 5.

86.8 SessionsTotalBytes

This Knowledge Script monitors the total number of input and output bytes used in a session. The total number of bytes includes memory used to handle any protocol overhead.

If the number of bytes used in a session exceeds the threshold you set, an event is raised.

86.8.1 Resource Objects

WTS Sessions

86.8.2 Default Schedule

The default interval is **Every 1 hour**.

86.8.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Raise event if number of bytes per session exceeds the threshold?	Set to **y** to raise an event if the number of bytes per session exceeds the threshold you set. The default is y.
Collect data for total bytes per session?	Set to **y** to collect data for charts and reports. If set to y, the script returns the number of bytes used by each session. The default is y.
Threshold – total bytes used per session	Specify the maximum number of bytes to be used per session before an event is raised. The default is 500.
Event severity if the number of bytes per session exceeds the threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default severity level is 5.

86.9 SessionsTotalDisconnected

This Knowledge Script monitors the total number of sessions that have been disconnected on a Windows terminal server. If the number of disconnected Windows Terminal Server (WTS) sessions exceeds the threshold you set, an event is raised.

86.9.1 Resource Objects

WTS Sessions

86.9.2 Default Schedule

The default interval is **Every 1 hour**.

86.9.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Raise an event if the total number of disconnected sessions exceeds the threshold?	Set to **y** to raise an event if the total number of disconnected sessions exceeds the threshold. The default is y.
Collect data for disconnected sessions?	Set to **y** to collect data for charts and reports. If set to y, this script returns the total number of disconnected sessions. The default is n.
Threshold – maximum disconnected sessions	Specify the maximum number of sessions to be disconnected before an event is raised. The default is 10.
Event severity when the total number of disconnected sessions exceeds the threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event in which the total number of disconnected sessions exceeds the threshold. The default severity level is 8.

86.10 SessionsTotalErrors

This Knowledge Script monitors the total number of session errors of all types. The total number of errors for a session can include lost acknowledgments, badly formed packets, and transmission problems. If the number of errors exceeds the threshold you set, an event is raised.

86.10.1 Resource Objects

WTS Sessions

86.10.2 Default Schedule

The default interval is **Every 1 hour**.

86.10.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Raise event if the number of errors per session exceeds the threshold?	Set to **y** to raise an event if the number of errors per session exceeds the threshold. The default is y.
Collect data for session errors?	Set to **y** to collect data for charts and reports. If set to y, this script returns the total number of errors for each session. The default is y.
Threshold – maximum session errors	Specify the maximum number of errors that can occur for any session before an event is raised. The default is 500.
Event severity when the number of errors per session exceeds the threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default severity level is 5.

86.11 SessionsTotalFrames

This Knowledge Script monitors the total number of frames (packets) transmitted in a session. If the number of frames exceeds the threshold you set, an event is raised.

86.11.1 Resource Objects

WTS Sessions

86.11.2 Default Schedule

The default interval is **Every 1 hour**.

86.11.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Raise event if the total number of frames per session exceeds the threshold?	Set to **y** to raise an event if the total number of frames per session exceeds the threshold. The default is y.
Collect data for frames transmitted per session?	Set to **y** to collect data for charts and reports. If set to y, this script returns the total number of frames for each session. The default is n.
Threshold – maximum transmitted frames	Specify the maximum number of frames to be transmitted in a session before an event is raised. The default is 30.
Event severity when the total number of frames per session exceeds the threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default severity level is 5.

86.12 SessionsTotalInactive

This Knowledge Script monitors the number of inactive Windows Terminal Server (WTS) sessions. An inactive session is one with no users logged on. If the number of inactive WTS sessions exceeds the threshold you set, an event is raised.

86.12.1 Resource Objects

WTS Sessions

86.12.2 Default Schedule

The default interval is **Every 1 hour**.

86.12.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Raise event if the number of inactive sessions exceeds the threshold?	Set to **y** to raise an event if the number of inactive sessions exceeds the threshold. The default is y.
Collect data for inactive sessions?	Set to **y** to collect data for charts and reports. If set to y, the script returns the total number of inactive sessions. The default is y.
Threshold – maximum inactive sessions	Specify the maximum number of sessions to be inactive before an event is raised. The default is 50.
Event severity when the number of inactive sessions exceeds the threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default severity level is 5.

86.13 SessionsTotalProtocolHitRatio

This Knowledge Script monitors the overall hit ratio for all protocol objects per session. The *hit ratio* is the percentage of time protocol objects that are reused or available in the client cache.

A higher hit ratio indicates reduced data transmission and better performance. A low hit ratio is caused when a session is updated with new information that is not re-used, or is not used within the number of bytes available for the client cache.

If the hit ratio for any session is lower than the threshold you set, an event is raised.

86.13.1 Resource Objects

WTS Sessions

86.13.2 Default Schedule

The default interval is **Every 1 hour**.

86.13.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Raise event if the protocol hit ratio is below threshold?	Set to **y** to raise an event if the protocol hit ratio is below threshold. The default is y.
Collect data for protocol hit ratio?	Set to **y** to collect data for charts and reports. If set to y, the script returns the overall hit ratio for all protocol objects per session. The default is n.
Threshold – minimum protocol hit ratio	Specify the minimum protocol hit ratio percentage per session to be reached before an event is raised. The default is 50.
Event severity if the protocol hit ratio is below threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event in which the protocol hit ratio is below threshold. The default severity level is 5.

86.14 TopCpuProcs

This Knowledge Script monitors CPU usage for all Windows Terminal Server (WTS) processes and the CPU used by the top number of processes specified by you. If the total percentage of CPU usage for the set of top processes exceeds the threshold you set, an event is raised.

You can specify the number of top processes to display in the detail message. The detail message includes the percentage of CPU used by each of the top processes.

86.14.1 Resource Object

WTS Server

86.14.2 Default Schedule

The default interval is **Every 30 minutes**.

86.14.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Raise event if CPU usage exceeds the threshold?	Set to **y** to raise an event if the CPU usage exceeds the threshold. The default is y.
Collect data for CPU usage by top processes?	Set to **y** to collect data for charts and reports. If set to y, the script returns the total CPU usage for the set of top processes. The default is n.
Threshold – maximum CPU usage	Specify the maximum percentage of CPU resources WTS processes can consume before raising an event. The default is 90.
Number of top CPU usage processes to show	Specify the number of top processes to display in the detail message. Specify 0 if you want to display all processes. The default is 5.
Event severity when CPU usage exceeds the threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event in which the CPU usage exceeds the threshold. The default severity level is 5.

86.15 TopCPUSessions

This Knowledge Script monitors CPU usage for all WTS sessions and monitors the CPU usage of the top number of sessions specified by you. If the total percentage of CPU usage for these sessions exceeds the threshold you set, an event is raised.

You can specify the number of top sessions to display in the detail message. The detail message includes the percentage of CPU usage used by each of the top sessions.

86.15.1 Resource Objects

WTS Sessions

86.15.2 Default Schedule

The default interval is **Every 30 minutes**.

86.15.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Raise event if CPU usage exceeds the threshold?	Set to **y** to raise an event if the CPU usage exceeds the threshold you set. The default is y.
Collect data for session CPU usage?	Set to **y** to collect data for charts and reports. If set to y, the script returns the total CPU usage for the top set of sessions. The default is n.
Threshold – total CPU usage	Specify a threshold for the maximum percentage of CPU resources WTS sessions can consume before raising an event. The default is 90.
Number of top CPU usage sessions to show	Specify the number of top sessions you want to display in the detail message. Specify 0 if you want to display all sessions. The default is 5.
Event severity when CPU usage exceeds the threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event in which the CPU usage exceeds the threshold. The default severity level is 5.

86.16 TopMemorySessions

This Knowledge Script monitors total memory usage for all sessions and the memory used by each of a specified set of sessions. If the memory usage of any of the sessions exceeds the threshold you set, an event is raised.

You can specify the number of top sessions to display in the detail message. The detail message includes the total memory used by each of the top set of sessions.

86.16.1 Resource Objects

WTS Sessions

86.16.2 Default Schedule

The default interval is **Every 30 minutes**.

86.16.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Raise event if session memory usage exceeds the threshold?	Set to **y** to raise an event if the session memory usage exceeds the threshold. The default is y.
Collect data for session memory usage?	Set to **y** to collect data for charts and reports. If set to y, the script returns the total memory usage for the top *n* number of sessions. The default is n.
Threshold – maximum memory usage	Specify the maximum memory the top *n* number of sessions can consume before raising an event. The default is 5120.
Number of top usage of memory sessions to show	Specify the number of top sessions you want to display in the detail message. Specify 0 if you want all to display all users. The default is 5.
Event severity when session memory usage exceeds the threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default severity level is 5.

86.17 UsersInfo

This Knowledge Script displays information about the users currently logged on to the Windows Terminal Server (WTS) server. The detailed message includes each user's name, session name, session ID, current status, idle time, and log on time. If the Knowledge Script cannot get information about WTS users, an event is raised.

86.17.1 Resource Objects

WTS Users

86.17.2 Default Schedule

The default interval is **Every 1 hour**.

86.17.3 Example of the Information Returned

The following is an example of the data collected and displayed in the data detail message:

```
USERNAME    SESSIONNAME     ID  STATE  IDLE TIME  LOGON TIME
>shawn      console          0  active          .  09/03/03 18:56
 netiq                       4  disc         none  09/04/03 10:32
 netiq      rdp-tcp#5        5  active         50  09/04/03 12:05
```

86.17.4 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
Collect data for logged-on users?	Set to **y** to collect data for charts and reports. If set to y, the script returns the number of users currently connected to WTS. The default is y.
Event severity if user information cannot be retrieved	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default severity level is 8.

87 XenApp Knowledge Scripts

AppManager provides the following Knowledge Scripts for monitoring servers that are running Citrix MetaFrame.

From the Knowledge Script view of Control Center, you can access more information about any NetIQ-supported Knowledge Script by selecting it and clicking **Help**. Or in the Operator Console, click any Knowledge Script in the Knowledge Script pane and press **F1**.

Knowledge Script	What It Does
ApplicationUsersHigh	Monitors the number of users running one or more applications across all sessions on a specific XenApp server.
ApplicationUsersHighAll	Monitors the number of users running one or more applications across all sessions in a server farm.
BytesTransferredPerUser	Monitors the number of bytes per user transferred between client computers and a XenApp server.
DataCollectorChanged	Monitors whether a zone's data collector has changed since the last monitoring interval.
DefaultDataCollector	Identifies the default data collector for a XenApp server.
FarmUserLoad	Monitors the number of users connected to each XenApp server in a server farm.
ICAAvgLatencyHigh	Monitors the average latency of ICA sessions on a XenApp server.
ICALatencyHigh	Monitors the most-recent measure of latency for ICA sessions on a XenApp server.
LicenseInUseHigh	Monitors the percentage of licenses in use.
PublishedApplicationDetails	Searches for specified applications that are on the list of published applications for XenApp server farms.
ServerFarmHealth	Monitors the health and availability of XenApp Server services in a designated server farm and monitors the farm for servers that are not responding.
ServerProcessesHigh	Monitors the number of processes on a XenApp server across all sessions.
ServerProcessesResourceHigh	Monitors the use of CPU and memory resources by processes on a XenApp server.
ServerSessionHigh	Monitors the number of sessions on a XenApp server.
SessionPerUser	Monitors the number of sessions on a XenApp server that are open for each user.
SessionState	Monitors the number of sessions matching specified states.

Knowledge Script	What It Does
UserResourcesHigh	Monitors the use of CPU and memory resources by users connected to a XenApp server.

87.1 ApplicationUsersHigh

Use this Knowledge Script to monitor the number of users across all sessions running applications published on a XenApp server. If the number of users falls below the minimum threshold or exceeds the maximum threshold, an event is raised.

NOTE: To gather data about all sessions on servers in a XenApp farm, run the ApplicationUsersHighAll Knowledge Script instead of this Knowledge Script.

If you are monitoring multiple applications, separate events are raised for each application. The same thresholds apply to all applications.

87.1.1 Resource Objects

Citrix XenApp Applications object or individual applications

87.1.2 Default Schedule

The default schedule is **Every 30 minutes**.

87.1.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
General Settings	
Job failure event notification	
Event severity when job fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the ApplicationUsersHigh job fails. The default is 5.
Event Notification	
Raise event if number of users exceeds or falls below threshold?	Select **Yes** to raise an event when the number of users running an application falls below the minimum threshold or exceeds the maximum threshold you set. The default is Yes.
Event severity when number of users exceeds or falls below threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 5.
Data Collection	
Collect data for number of users?	Select **Yes** to collect data for charts and reports. If enabled, returns information about the number of users running an application. The default is not selected.
Monitoring	
Threshold – Minimum number of users	Specify the minimum number of users across all sessions that can be running a published application before an event is raised. The value can range from 0 to 99998 users, and must be lower than the threshold for the maximum number of users. The default is 5.

Description	How to Set It
Threshold – Maximum number of users	Specify the maximum number of users across all sessions that can be running a published application before an event is raised. The value can range from 1 to 99999 users, and must be higher than the threshold for the minimum number of users. The default is 50.

87.2 ApplicationUsersHighAll

Use this Knowledge Script to monitor the number of users across all sessions running applications published in a XenApp farm. If the number of users falls below the minimum threshold or exceeds the maximum threshold, an event is raised.

NOTE: To monitor users on an individual server instead of a XenApp farm, use the ApplicationUsersHigh Knowledge Script instead of this Knowledge Script.

If you are monitoring multiple applications, separate events are raised for each application. The same thresholds apply to all applications.

87.2.1 Resource Objects

Citrix XenApp Applications object or individual applications

87.2.2 Default Schedule

The default schedule is **Every 30 minutes**.

87.2.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
General Settings	
Job failure event notification	
Event severity when job fails	Set the severity level, from 1 to 40, to indicate the importance of an event where the ApplicationUsersHighAll job fails. The default is 5.
Event Notification	
Raise event if number of users exceeds or falls below threshold?	Select **Yes** to raise an event when the number of users running an application falls below the minimum threshold or exceeds the maximum threshold you set. The default is Yes.
Event severity when number of users exceeds or falls below threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 5.
Data Collection	
Collect data for number of users?	Select **Yes** to collect data for charts and reports. If enabled, returns information about the number of users running an application. The default is not selected.
Monitoring	
Threshold – Minimum number of users	Specify the minimum number of users across all sessions that can be running a published application before an event is raised. The value can range from 0 to 99998 users, and must be lower than the threshold for the maximum number of users. The default is 5.

Description	How to Set It
Threshold – Maximum number of users	Specify the maximum number of users across all sessions that can be running a published application before an event is raised. The value can range from 1 to 99999 users, and must be higher than the threshold for the minimum number of users. The default is 50.

87.3 BytesTransferredPerUser

Use this Knowledge Script to monitor the number of bytes per user transferred between client computers and the XenApp server.

The number of bytes is calculated by taking the total of all bytes for all Independent Computing Architecture (ICA) sessions currently active for a user. For each user with one or more ICA protocol sessions on XenApp, the sum of bytes transferred by all sessions associated with that user is compared to the threshold you set. If the number of bytes exceeds the threshold, an event is raised.

87.3.1 Resource Objects

Citrix XenApp object

87.3.2 Default Schedule

The default schedule is **Every 5 minutes**.

87.3.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
General Settings	
Job failure event notification	
Event severity when job fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the BytesTransferredPerUser job fails. The default is 5.
Event Notification	
Raise event if the total number of bytes transferred for a user exceeds threshold?	Select **Yes** to raise an event if the total bytes per user exceeds the threshold. The default is Yes.
Event severity when the total number of bytes transferred for a user exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the total bytes per user exceeds the threshold you set. The default is 5.
Data Collection	
Collect data for bytes transferred per user?	Select **Yes** to collect data for charts and reports. If enabled, returns information about the number of bytes per user transferred between ICA clients and XenApp. The default is unselected.
Monitoring	
Threshold – Maximum bytes transferred per user	Specify the maximum number of bytes that can be transferred per user before an event is raised. The default is 10485760 bytes.

87.4 DataCollectorChanged

Use this Knowledge Script to determine whether the data collector for a XenApp server zone has changed since the last time the script was run. If a change to the data collector for the selected zone is detected, an event is raised.

87.4.1 Resource Objects

Citrix XenApp Zones object or individual zones

87.4.2 Default Schedule

The default schedule is **Every 30 minutes**.

87.4.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
General Settings	
Job failure event notification	
Event severity when job fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the DataCollectorChanged job fails. The default is 5.
Event Notification	
Raise event if a change to the data collector is detected?	Select **Yes** to raise an event if a change to the data collector for this server zone has occurred since the last monitoring interval. The default is Yes.
Event severity when a change is detected	Set the event severity level, from 1 to 40, to indicate the importance of an event in which a change to the data collector occurs. The default is 5.
Data Collection	
Collect data for data collector changes?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns one of the following values: • **100** if the data collector has changed • **0** if the data collector has not changed The default is unselected.

87.5 DefaultDataCollector

Use this Knowledge Script to identify the default data collector for a specific XenApp server under a XenApp farm, or to identify *all* available XenApp servers under a XenApp farm.

This script raises an event if the default data collector information is found, and the event message includes default data collector and zone information for the selected XenApp server.

If you run this script on the server object, the event returns the zone name and the default data collector for all the servers that are discovered under server object. If you run this script on a particular server or set of servers, the event returns the zone name and default data collector for those servers only.

87.5.1 Resource Object

XenApp Servers object or individual servers

87.5.2 Default Schedule

By default, this script is only run once for each server.

87.5.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
General Settings	
Job failure event notification	
Event severity when job fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the DefaultDataCollector job fails. The default is 5.
Event Notification	
Event severity when default data collector information is found	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the default data collector information is found. The default is 15.
Event severity when user is not a Citrix XenApp farm administrator	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the user is not a XenApp farm administrator. The default is 11.

87.6 FarmUserLoad

Use this Knowledge Script to monitor the number of users connected to each XenApp server in a server farm. You can set thresholds for the minimum and maximum number of users. An event is raised if the maximum threshold is exceeded or the minimum threshold is not met.

In addition, you can set thresholds based on a standard deviation, calculated from the number of users connected to each server in the farm since the first job iteration. The maximum and minimum thresholds for individual servers are defined by the number of standard deviations above or below the average number of users connected to all servers since the first iteration of the job.

If you use the standard deviation thresholds, the thresholds for the minimum and maximum numbers of users are ignored.

You can also specify servers in a farm that are to be excluded from monitoring by this Knowledge Script.

87.6.1 Resource Object

XenApp Farm object

87.6.2 Default Schedule

The default schedule is **Every 30 minutes**.

87.6.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
General Settings	
Job failure event notification	
Event severity when job fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the FarmUserLoad job fails. The default is 5.
Event Notification	
Raise event if any threshold exceeded or not met?	Select **Yes** to raise an event if the number of standard deviations or the number of users exceeds or falls below one of the thresholds you set. The default is Yes.
Event severity when any threshold exceeded or not met	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of standard deviations or the number of users exceeds or falls below a threshold. The default is 5.
Data Collection	
Collect data for number of users?	Select **Yes** to collect data for charts and reports. If enabled, returns the numbers of users connected to XenApp. The default is unselected.
Monitoring	

Description	How to Set It
Type of threshold to use?	Select the type of threshold to use: • Standard Deviation • Minimum/Maximum The default is `Minimum/Maximum`.
Standard Deviation Settings	
Threshold – Number of standard deviations below average	Specify the number of standard deviations below the average number of users connected to all servers in the farm. If the number of users of a particular server falls below this threshold, an event is raised. The default is 1.
Threshold – Number of standard deviations above average	Specify the number of standard deviations above the average number of users connected to all servers in the farm. If the number of users of a particular server exceeds this threshold, an event is raised. The default is 1.
Minimum/Maximum Settings	
Threshold – Minimum number of users	Specify the minimum number of users who must be connected to a server before an event is raised. The value must be lower than the threshold for the maximum number of users. The default is 10 users.
Threshold – Maximum number of users	Specify the maximum number of users who can be connected to a server before an event is raised. The value must be higher than the threshold for the maximum number of users. The default is 50 users.
Servers to exclude (comma-separated, no spaces)	Provide a list of server names, separated by commas and no spaces (for example, `MFServer1,MFServer2,MFServer3`). Servers specified in this parameter are not monitored by this Knowledge Script.

87.7 ICAAvgLatencyHigh

Use this Knowledge Script to monitor the average latency, in milliseconds, for Independent Computing Architecture (ICA) sessions on a XenApp server. Latency refers to the delay between user input, such as mouse movement or keyboard strokes, and screen refresh.

Each time this Knowledge Script runs, it checks the average latency of each ICA session for the length of time the session has been open. If the average latency of any session exceeds the threshold you set, an event is raised.

Use the ICALatencyHigh Knowledge Script to monitor the most recently measured latency for each ICA session. If latency consistently exceeds the threshold you set, you can use the Citrix SpeedScreen Latency Reduction Manager to adjust your SpeedScreen settings.

87.7.1 Resource Objects

Citrix XenApp object

87.7.2 Default Schedule

The default schedule is **Every 30 minutes**.

87.7.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
General Settings	
Job failure event notification	
Event severity when job fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the ICAAvgLatencyHigh job fails. The default is 5.
Event Notification	
Raise event if average latency exceeds threshold?	Select **Yes** to raise an event if the average latency for ICA sessions exceeds the threshold. The default is Yes.
Event severity when average latency exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which average latency exceeds the threshold you set. The default is 5.
Data Collection	
Collect data for average latency?	Select **Yes** to collect data for charts and reports. If enabled, returns the average latency of each ICA session for the length of time the session has been open. The default is unselected.
Monitoring	
Threshold – Maximum average latency of an ICA session	Specify a maximum threshold, in milliseconds, for the average latency for any ICA session. The default is 30 milliseconds.

87.8 ICALatencyHigh

Use this Knowledge Script to monitor the most recent or current measure of latency for each Independent Computing Architecture (ICA) session on a XenApp server. Latency refers to the delay between user input, such as mouse movement or keyboard strokes, and screen refresh.

If the most recent measure of latency for any ICA session exceeds the threshold you set, an event is raised.

Use the ICAAvgLatencyHigh Knowledge Script to monitor the average latency of all ICA sessions over time. If latency consistently exceeds the threshold you set, you can use the SpeedScreen Latency Reduction Manager to adjust your SpeedScreen settings.

87.8.1 Resource Objects

Citrix XenApp object

87.8.2 Default Schedule

The default schedule is **Every 30 minutes**.

87.8.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
General Settings	
Job failure event notification	
Event severity when job fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the ICALatencyHigh job fails. The default is 5.
Event Notification	
Raise event if current latency exceeds threshold?	Select **Yes** to raise an event if the current latency for any ICA session exceeds the threshold. The default is Yes.
Event severity when current latency exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which latency exceeds the threshold you set. The default is 5.
Data Collection	
Collect data for current latency of ICA sessions?	Select **Yes** to collect data for charts and reports. If enabled, returns the most recent measure of latency for each ICA session. The default is unselected.
Monitoring	
Threshold – Maximum current latency of an ICA session	Specify the maximum latency amount (in milliseconds) any ICA session can have before an event is raised. The default is 30.

87.9 LicenseInUseHigh

Use this Knowledge Script to monitor the percentage of licenses in use for Citrix XenApp. If the percentage of licenses in use exceeds the threshold you set, an event is raised.

Citrix XenApp use a license server with license files that grant connection rights to a client. When a client connects to the server, one license is allocated. License servers can be shared by multiple server farms, and in such a case, a client can connect to either farm and consume only one license.

LicenseInUseHigh is cluster-aware. It monitors and collects data for active nodes, for all the available license types on the server. Even if you have two child jobs for LicenseInUseHigh, the script monitors and collects data for active nodes only. The LicenseInUseHigh job does not stop if the state of the cluster node changes, such as when the passive node of the cluster becomes active, or the active node becomes passive. In the event of a failover, LicenseInUseHigh monitors all the license types available on the server.

If data collection is enabled, this Knowledge Script returns the percentage of licenses in use compared to the total number of licenses available on the license server.

87.9.1 Resource Object

For clustered environments, Citrix XenApp License object

For non-clustered environments. Citrix XenApp License object or individual license files

87.9.2 Default Schedule

The default schedule is **Every 30 minutes**.

87.9.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
General Settings	
Job failure event notification	
Event severity when job fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the LicenseInUseHigh job fails. The default is 5.
Event Notification	
Raise event if percentage of licenses in use exceeds threshold?	Select **Yes** to raise an event if the percentage of licenses in use exceeds the threshold. The default is Yes.
Event severity when percentage of licenses in use exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the percentage of licenses in use exceeds the threshold. The default is 5.
Data Collection	
Collect data for percentage of licenses in use?	Select **Yes** to collect data for charts and reports. If enabled, returns the percentage of licenses in use. The default is unselected.
Monitoring	
Threshold – Maximum percentage of licenses in use	Specify the maximum percentage of licenses that can be in use before an event is raised. The default is 80%.

87.10 PublishedApplicationDetails

This Knowledge Script searches for specified applications that are on the list of published applications for Citrix Server farms. This script raises an event that lists details about the published application or the list of applications, including the name of the farms and servers on which the application has been published.

87.10.1 Resource Objects

Citrix XenApp Farm object

87.10.2 Default Schedule

By default, this script is only run once for each server.

87.10.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
General Settings	
Job failure event notification	
Event severity when job fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the PublishedApplicationDetails job fails. The default is 5.
Applications to be verified in the published application list (comma-separated)	Type the name of the application or applications you want to determine is in the published application list. For more than one application, separate the application names with a comma, no space. This parameter supports the wildcard characters "*" and "?" for published applications.
Event Notification	
Event severity when specified application details are found	Set the event severity level, from 1 to 40, to indicate the importance of the event raised when specific application details are found. The default is 15.
Event severity when user is not a Citrix farm administrator	Set the event severity level, from 1 to 40, to indicate the importance of the event raised when the user is not a XenApp farm administrator. The default is 11.

87.11 ServerFarmHealth

Use this Knowledge Script to monitor a XenApp server farm for unresponsive servers. You can set two thresholds for non-responding servers:

- The maximum number of servers that are unresponsive before a **warning** event is raised
- The maximum number of servers that are unresponsive before an **error** event is raised

This script raises an event if either threshold is exceeded. You can set severity levels for each event type.

You can also use this script to monitor the health and availability of the following services in a designated farm. The services in a designated farm must be running before you can collect data.

- Client Network
- Encryption
- Independent Management Architecture
- MFCOM (XenApp Management SDK)
- Licensing
- Services Manager
- XTE Server
- XML Server

Each service can display one of the following statuses:

- **Running** — The service is running.
- **Not running** — The service is not running.

87.11.1 Resource Objects

XenApp Farm object

87.11.2 Default Schedule

The default schedule is **Every 10 minutes**.

87.11.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
General Settings	
Job failure event notification	
Event severity when job fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the ServerFarmHealth job fails. The default is 5.

Description	How to Set It
Event Notification	
Raise event if number of servers not responding exceeds threshold?	Select **Yes** to raise an event if the number of unresponsive servers exceeds the thresholds you set. The default is Yes.
Raise event to display the status of XenApp Server services in a farm?	Select **Yes** to raise an event to display the status of XenApp server services in a designated farm. The default is Yes.
Warning event severity when the threshold is exceeded	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the warning threshold is exceeded. The default is 11.
Error event severity when the threshold is exceeded	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the error threshold is exceeded. The default is 5.
Event severity when the service is down	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the XenApp server service is down. The default is 5.
Data Collection	
Collect data for XenApp servers not responding?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the percentage of servers in the server farm that are down. If any servers are down, the data details include the names of servers that are unresponsive. The default is unselected.
Collect data for XenApp services in a farm?	Select **Yes** to collect data for charts and reports. If enabled, data collection returns the percentage of XenApp server services in the farm that are down. The default is unselected.
Monitoring	
Servers to ignore	Provide a list of servers you do not want to monitor. Use commas with no spaces to separate server names in a list. For example, `MFServer1,MFServer2,MFServer3`. You can also click **Browse [...]** to use a network browser to select computer names.
Services to Ignore	
Ignore Client Network Service?	Select **Yes** to allow the script to ignore the Client Network Service during monitoring of the selected XenApp server. The default is unselected. This option is useful when the Client Network Service is on a different server than the one you are monitoring. When this option is enabled, the ServerFarmHealth job does not raise an event if it cannot locate the Client Network Service.
Ignore Encryption Service?	Select **Yes** to allow the script to ignore the Encryption Service during monitoring of the selected XenApp server. The default is unselected. This option is useful when the Encryption Service is on a different server than the one you are monitoring. When this option is enabled, the ServerFarmHealth job does not raise an event if it cannot locate the Encryption Service.

Description	How to Set It
Ignore Independent Management Architecture Service?	Select **Yes** to allow the script to ignore the Independent Management Architecture Service during monitoring of the selected XenApp server. The default is unselected. This option is useful when the Independent Management Architecture Service is on a different server than the one you are monitoring. When this option is enabled, the ServerFarmHealth job does not raise an event if it cannot locate the Independent Management Architecture Service.
Ignore MFCom Service?	Select **Yes** to allow the script to ignore the MFCom Service during monitoring of the selected XenApp server. The default is unselected. This option is useful when the MFCom Service is on a different server than the one you are monitoring. When this option is enabled, the ServerFarmHealth job does not raise an event if it cannot locate the MFCom Service.
Ignore Citrix Licensing Service?	Select **Yes** to allow the script to ignore the Licensing Service during monitoring of the selected XenApp server. The default is unselected. This option is useful when the Licensing Service is on a different server than the one you are monitoring. When this option is enabled, the ServerFarmHealth job does not raise an event if it cannot locate the Licensing Service.
Ignore Citrix Services Manager?	Select **Yes** to allow the script to ignore the Services Manager during monitoring of the selected XenApp server. The default is unselected. This option is useful when the Services Manager is on a different server than the one you are monitoring. When this option is enabled, the ServerFarmHealth job does not raise an event if it cannot locate the Services Manager.
Ignore Citrix XTE Server?	Select **Yes** to allow the script to ignore the XTE Server service during monitoring of the selected XenApp server. The default is unselected. This option is useful when the XTE Server is on a different computer than the one you are monitoring. When this option is enabled, the ServerFarmHealth job does not raise an event if it cannot locate the Citrix XTE Server service.
Ignore Citrix XML Server?	Select **Yes** to allow the script to ignore the XML Server service during monitoring of the selected XenApp server. The default is unselected. This option is useful when the XML Server is on a different computer than the one you are monitoring. When this option is enabled, the ServerFarmHealth job does not raise an event if it cannot locate the XML Server service.
Warning event threshold – Maximum number of servers not responding	Specify the maximum number of servers that can be detected as not responding before a warning event is raised. The default is 3 servers.
Error event threshold – Maximum number of servers not responding	Specify the maximum number of servers that can be detected as not responding before an error event is raised. The default is 10 servers.

87.12 ServerProcessesHigh

Use this Knowledge Script to monitor the number of XenApp processes across all sessions. If the number of server processes exceeds the specified threshold, an event is raised.

NOTE: To gather data about all sessions on a specific server in a XenApp farm, run this Knowledge Script on that individual server in the farm.

This script returns the number of processes generated by all sessions on XenApp server. The event detail message includes information about each process, such as process name, process state, process ID, and username.

87.12.1 Resource Object

Citrix XenApp object

87.12.2 Default Schedule

The default schedule is **Every 30 minutes**.

87.12.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
General Settings	
Job failure event notification	
Event severity when job fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the ServerProcessesHigh job fails. The default is 5.
Event Notification	
Raise event if number of processes exceeds the threshold?	Select **Yes** to raise an event if the number of XenApp processes across all sessions exceeds the specified threshold. The default is Yes.
Event severity when number of processes exceeds the threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event. The default is 5.
Data Collection	
Collect data for number of processes?	Select **Yes** to collect data for charts and reports. If enabled, returns the number of XenApp processes across all sessions. The default is unselected.
Monitoring	
Threshold – Maximum processes on a server	Specify the maximum number of processes allowed on a server across all sessions before an event is raised. The default is 50 processes.

87.13 ServerProcessesResourceHigh

Use this Knowledge Script to monitor the use of CPU and memory resources by processes on XenApp servers.

You can set thresholds for physical and virtual memory utilization and CPU utilization. If the use of resources by a process exceeds a threshold you set, an event is raised.

You can also configure the Knowledge Script to automatically terminate processes that exceed usage thresholds.

87.13.1 Resource Object

Citrix XenApp object

87.13.2 Default Schedule

The default schedule is **Every 30 minutes**.

87.13.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
General Settings	
Job failure event notification	
Event severity when job fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the ServerProcessesResourceHigh job fails. The default is 5.
Event Notification	
Raise event if memory or CPU utilization exceeds threshold?	Select **Yes** to raise an event when the use of physical or virtual memory or CPU time exceeds the threshold you set. By default, events are enabled.
Event severity when memory or CPU utilization exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which memory or CPU utilization exceeds the threshold you set. The default is 5.
Data Collection	
Collect data for memory and CPU utilization?	Select **Yes** to collect data for charts and reports. If enabled, returns information about the use of physical and virtual memory (in KB) and CPU time (as a percentage). The default is unselected.
Monitoring	
Threshold – Maximum physical memory utilization	Specify the maximum amount of physical memory that can be used by any single XenApp process before an event is raised. The default is 30720 KB.

Description	How to Set It
Threshold – Maximum virtual memory utilization	Specify the maximum amount of virtual memory that can be used by any single XenApp process before an event is raised. The default is 61440 KB.
Threshold – Maximum CPU utilization	Specify the maximum percentage of CPU time that can be used by any single XenApp process before an event is raised. The default is 90%.
Processes to monitor (comma-separated, no spaces)	Provide the names of the XenApp processes you want to monitor. Separate multiple process names with commas and no spaces. For example, `Process1,Process2,Process3`. If no process names are entered, all processes are monitored. By default, all processes are monitored.
Terminate processes that exceed a threshold?	Select **Yes** to terminate any listed processes whose use of memory or CPU time exceeds the thresholds you set. The default is unselected.

87.14 ServerSessionHigh

Use this Knowledge Script to monitor the number of sessions on a XenApp server. If the number of sessions exceeds the threshold you set, an event is raised.

If data collection is enabled, this script returns the number of server sessions. The event detail message includes information about each session, such as session name, session ID, and username.

87.14.1 Resource Object

Citrix XenApp object

87.14.2 Default Schedule

The default schedule is **Every 30 minutes**.

87.14.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
General Settings	
Job failure event notification	
Event severity when job fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the ServerSessionHigh job fails. The default is 5.
Event Notification	
Raise event if number of sessions exceeds threshold?	Select **Yes** to raise an event if the number of server sessions exceeds the threshold. The default is Yes.
Event severity when number of sessions exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of sessions exceeds threshold. The default is 5.
Data Collection	
Collect data for number of sessions?	Select **Yes** to collect data for charts and reports. If enabled, returns the number of sessions, and information about each session. The default is unselected.
Monitoring	
Threshold – Maximum number of sessions on a server	Specify the maximum number of sessions allowed on a server before an event is raised. The default is 20 sessions.

87.15 SessionPerUser

Use this Knowledge Script to monitor the number of sessions open for each user. You can monitor individual servers or entire server farms. If the number of sessions per user exceeds the threshold you specify, an event is raised.

87.15.1 Resource Object

Citrix XenApp object

87.15.2 Default Schedule

The default schedule is **Every 30 minutes**.

87.15.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
General Settings	
Job failure event notification	
Event severity when job fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the SessionPerUse job fails. The default is 5.
Event Notification	
Raise event if number of sessions exceeds threshold?	Select **Yes** to raise an event if the number of user sessions exceeds the threshold you set. The default is Yes.
Event severity when number of sessions exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of sessions exceeds the threshold you set. The default is 5.
Data Collection	
Collect data for number of sessions?	Select **Yes** to collect data for charts and reports. If enabled, returns the number of sessions on XenApp open for each user. The default is unselected.
Monitoring	
Threshold – Maximum number of sessions	Specify the maximum number of sessions on XenApp that can be open for each user before an event is raised. The default is 5 sessions.
Monitor all servers in the farm?	Select **Yes** to monitor the number of sessions for all servers in a farm. The default is unselected.

87.16 SessionState

Use this Knowledge Script to monitor for Independent Computing Architecture (ICA) sessions that are in certain states. SessionState Knowledge Script can now monitor XenApp server sessions per farm, generating event messages by farm name instead of server name.

If the number of sessions matching the states you select for monitoring falls below the minimum threshold or exceeds the maximum threshold you set, an event is raised.

SessionState obtains a list of all sessions from the XenApp API and loops through that list, looking at the state of each session. As an example, set the **Minimum threshold** to 2 and the **Maximum threshold** to 4. If this Knowledge Script finds two sessions in `LISTENING` state, and one in `ACTIVE` state, the number of sessions in `LISTENING` state is between the minimum and maximum thresholds, so the Knowledge Script will not raise an event for that state. The number of `ACTIVE` sessions has fallen below the minimum threshold, so the script raises an event for the `ACTIVE` state.

In a case like the one cited above, the Knowledge Script would not raise an event for any other session state, even if other states had fallen below the minimum threshold. It only raises events for a state if at least one session is in that particular state.

One use for this script is to track the number of active or idle XenApp sessions.

87.16.1 Resource Object

Citrix XenApp object

87.16.2 Default Schedule

The default schedule is **Every 30 minutes**.

87.16.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
General Settings	
Job failure event notification	
Event severity when job fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the SessionState job fails. The default is 5.
Event Notification	
Raise event when threshold exceeded or not met?	Select **Yes** to raise an event if the number of sessions matching a specified state exceeds or falls below the maximum or minimum threshold. The default is Yes.
Event severity when threshold exceeded or not met	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the number of sessions exceeds or falls below the threshold you set. The default is 5.
Data Collection	

Description	How to Set It
Collect data for number of server sessions in specified state?	Select **Yes** to collect data for charts and reports. If enabled, returns the number of sessions matching specified states. The default is unselected.
Monitoring	
Threshold – Minimum number of sessions matching specified states	Specify the minimum number of sessions whose states must match the states you selected for monitoring before an event is raised. The default is 0 sessions (disabled).
Threshold – Maximum number of sessions matching specified states	Specify the maximum number of sessions whose states can match the states you selected for monitoring before an event is raised. The default is 5 sessions.
Session States to Monitor	
All session states	Select **Yes** for each type of session state you want to monitor. By default, only **All session states** is set to Yes.

87.17 UserResourcesHigh

Use this Knowledge Script to monitor the utilization of CPU time and memory resources by users connected to XenApp. You can select which users to monitor and set thresholds for physical or virtual memory utilization or CPU utilization.

Monitoring a user's processes occurs on a per-process basis. Resource utilization is only measured for the processes being used by the user selected for monitoring. However, the utilization metrics of different processes are not aggregated per user. All users on the server where you dropped the Knowledge Script are monitored by default. When user runs multiple instances of a process, each process instance has a pound sign (#) then a number after the process name so you can easily see how many instances of that process are running for that user.

If the percentage of CPU time or the amount of physical or virtual memory used by a process exceeds a threshold you set, an event is raised.

87.17.1 Resource Object

Citrix XenApp object

87.17.2 Default Schedule

The default schedule is **Every 30 minutes**.

87.17.3 Setting Parameter Values

Set the following parameters as needed:

Description	How to Set It
General Settings	
Job failure event notification	
Event severity when job fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the UserResourcesHigh job fails. The default is 5.
Event Notification	
Raise event when CPU or memory utilization exceeds threshold?	Select **Yes** to raise an event when the use of CPU or memory resources by users connected to XenApp exceeds any threshold you set. The default is Yes.
Event severity when CPU or memory utilization exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of an event in which the CPU or memory utilization exceeds the threshold you set. The default is 5.
Data Collection	
Collect data for CPU and memory utilization?	Select **Yes** to collect data for charts and reports. If enabled, returns information about the use of CPU and memory resources by users connected to XenApp. The default is unselected.
Monitoring	

Description	How to Set It
Threshold – Maximum physical memory utilization	Specify the maximum amount of physical memory that can be consumed by users connected to XenApp before an event is raised. The default is 30720 KB.
Threshold – Maximum virtual memory utilization	Specify the maximum amount of virtual memory that can be consumed by users connected to XenApp before an event is raised. The default is 61440 KB.
Threshold – Maximum CPU utilization	Specify the maximum percentage of CPU time that can be consumed by users connected to XenApp before an event is raised. The default is 80%.
Users to monitor (comma-separated, no spaces)	Provide the names of the users you want to monitor. Separate names in a list with commas and no spaces (for example, `User1,User2,User3`). If no names are entered, all users are monitored. By default, all users are monitored.

88 XenDesktop Knowledge Scripts

AppManager for Citrix XenDesktop and XenApp provides the following Knowledge Scripts for monitoring servers that are running Citrix XenDesktop or XenApp.

From the Knowledge Script view of Control Center, you can access more information about any NetIQ-supported Knowledge Script by selecting it and clicking **Help**. Or in the Operator Console, click any Knowledge Script in the Knowledge Script pane and press **F1**.

Knowledge Script	What It Does
ApplicationUsage	Monitors the total instances of all applications and separate instances for each of the applications that are running.
DatabaseActivity	Monitors the activity of the databases associated with the Broker, Host, and Machine Creation XenDesktop services.
EventLog	Monitors the Windows Application event log and custom Citrix logs for Citrix XenDesktop or XenApp error or warning events.
LicenseStatus	Monitors the license usage and license expiration of XenDesktop or XenApp servers.
MachineFailures	Monitors the number and type of failures that have occurred on machines in delivery groups on a XenDesktop or XenApp server.
MachineRegistration	Monitors the registration state of XenDesktop or XenApp servers.
ServiceStatus	Monitors the status of Citrix XenDesktop services.
Sessions	Monitors the status and number of sessions that exist on XenDesktop or XenApp servers.

88.1 ApplicationUsage

Use the XenDesktop_ApplicationUsage Knowledge Script to monitor the total instances of all applications and separate instances for each of the applications that are running.

This script raises an event if the total number of application instances or the number of instances of an application exceeds the thresholds you set. You can also choose to collect data on the total number of applications running.

88.1.1 Resource Objects

Citrix XenDesktop or XenApp Applications folder object or individual application object

88.1.2 Default Schedule

The default schedule is every 15 minutes.

88.1.3 Setting Parameter Values

Set the following parameters on the **Values** tab as needed:

Description	How to Set It
General Settings	
Job failure event notification	
Event severity when job fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the ApplicationUsage job fails. The default is 5.
Monitor Total Application Instances	
Event Notification	
Raise event if total number of application instances exceeds threshold?	Select **Yes** to raise an event when the total number of application instances exceeds the threshold you set. The default is Yes.
Threshold - Maximum number of total application instances	Specify the maximum number of total applications instances that can exist before an event is raised. The default is 50 applications.
Event severity when total number of application instances exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event in which the total number of application instances is exceeded. The default is 10.
Data Collection	
Collect data for total number of all application instances?	Select **Yes** to collect data for the total number of all application instances. The default is unselected.
Monitor Running Instances per Application	
Event Notification	
Raise event if number of instances of an application exceeds threshold?	Select **Yes** to raise an event when the number of instances of an application exceeds the threshold you set. The default is Yes.

Description	How to Set It
Threshold - Maximum number of instances of an application	Specify the maximum number of instances of an application that can exist before an event is raised. The default is 10 instances.
Event severity when number of instances of an application exceeds threshold?	Set the event severity level, from 1 to 40, to indicate the importance of the event in which the number of instances of an application is exceeded. The default is 10.

88.2 DatabaseActivity

Use the XenDesktop_DatabaseActivity Knowledge Script to Monitors the activity of the databases associated with the Broker, Host, and Machine Creation XenDesktop services.

This script raises an event if the average transaction time, the average transaction rate, or the transaction error rate exceeds the thresholds you set for those three services. You can also choose to collect data on those metrics.

88.2.1 Resource Objects

Citrix XenDesktop or XenApp site object

88.2.2 Default Schedule

The default schedule is every 15 minutes.

88.2.3 Setting Parameter Values

Set the following parameters on the **Values** tab as needed:

Description	How to Set It
General Settings	
Job failure event notification	
Event severity when job fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the DatabaseActivity job fails. The default is 5.
Monitor Broker Service	
Event Notification	
Raise event if average transaction time exceeds threshold?	Select **Yes** to raise an event when the average transaction time for the Broker service exceeds threshold. The default is Yes.
Threshold - Maximum average transaction time	Specify the maximum average transaction time for the Broker service that can exist before an event is raised. The default is 5000 milliseconds.
Event severity when average transaction time is exceeded	Set the event severity level, from 1 to 40, to indicate the importance of the event in which the average transaction time for the Broker service is exceeded. The default is 10.
Raise event if transaction rate exceeds threshold?	Select **Yes** to raise an event when the transaction rate for the Broker service exceeds threshold. The default is Yes.
Threshold - Maximum transaction rate	Specify the maximum transaction rate for the Broker service that can exist before an event is raised. The default is 20 transactions per second.
Event severity when transaction rate is exceeded	Set the event severity level, from 1 to 40, to indicate the importance of the event in which the transaction rate for the Broker service is exceeded. The default is 10.

Description	How to Set It
Raise event if transaction error rate exceeds threshold?	Select **Yes** to raise an event when the transaction error rate for the Broker service exceeds threshold. The default is Yes.
Threshold - Maximum transaction error rate	Specify the maximum transaction error rate for the Broker service that can exist before an event is raised. The default is 0 errors per seconds.
Event severity when transaction error rate is exceeded	Set the event severity level, from 1 to 40, to indicate the importance of the event in which the transaction error rate for the Broker service is exceeded. The default is 10.
Data Collection	
Collect data for Broker service?	Select **Yes** to collect data for the Broker service. The default is unselected.
Monitor Host Service	
Event Notification	
Raise event if average transaction time exceeds threshold?	Select **Yes** to raise an event when the average transaction time for the Host service exceeds threshold. The default is Yes.
Threshold - Maximum average transaction time	Specify the maximum average transaction time for the Host service that can exist before an event is raised. The default is 5000 milliseconds.
Event severity when average transaction time is exceeded	Set the event severity level, from 1 to 40, to indicate the importance of the event in which the average transaction time for the Host service is exceeded. The default is 10.
Raise event if transaction rate exceeds threshold?	Select **Yes** to raise an event when the transaction rate for the Host service exceeds threshold. The default is Yes.
Threshold - Maximum transaction rate	Specify the maximum transaction rate for the Host service that can exist before an event is raised. The default is 20 transactions per second.
Event severity when transaction rate is exceeded	Set the event severity level, from 1 to 40, to indicate the importance of the event in which the transaction rate for the Host service is exceeded. The default is 10.
Raise event if transaction error rate exceeds threshold?	Select **Yes** to raise an event when the transaction error rate for the Host service exceeds threshold. The default is Yes.
Threshold - Maximum transaction error rate	Specify the maximum transaction error rate for the Host service that can exist before an event is raised. The default is 0 errors per seconds.
Event severity when transaction error rate is exceeded	Set the event severity level, from 1 to 40, to indicate the importance of the event in which the transaction error rate for the Host service is exceeded. The default is 10.
Data Collection	
Collect data for Host service?	Select **Yes** to collect data for the Host service. The default is unselected.
Monitor Machine Creation Service	
Event Notification	
Raise event if average transaction time exceeds threshold?	Select **Yes** to raise an event when the average transaction time for the Machine Creation service exceeds threshold. The default is Yes.

Description	How to Set It
Threshold - Maximum average transaction time	Specify the maximum average transaction time for the Machine Creation service that can exist before an event is raised. The default is 5000 milliseconds.
Event severity when average transaction time is exceeded	Set the event severity level, from 1 to 40, to indicate the importance of the event in which the average transaction time for the Machine Creation service is exceeded. The default is 10.
Raise event if transaction rate exceeds threshold?	Select **Yes** to raise an event when the transaction rate for the Machine Creation service exceeds threshold. The default is Yes.
Threshold - Maximum transaction rate	Specify the maximum transaction rate for the Machine Creation service that can exist before an event is raised. The default is 20 transactions per second.
Event severity when transaction rate is exceeded	Set the event severity level, from 1 to 40, to indicate the importance of the event in which the transaction rate for the Machine Creation service is exceeded. The default is 10.
Raise event if transaction error rate exceeds threshold?	Select **Yes** to raise an event when the transaction error rate for the Machine Creation service exceeds threshold. The default is Yes.
Threshold - Maximum transaction error rate	Specify the maximum transaction error rate for the Machine Creation service that can exist before an event is raised. The default is 0 errors per seconds.
Event severity when transaction error rate is exceeded	Set the event severity level, from 1 to 40, to indicate the importance of the event in which the transaction error rate for the Machine Creation service is exceeded. The default is 10.
Data Collection	
Collect data for Machine Creation service?	Select **Yes** to collect data for the Machine Creation service. The default is unselected.

88.3 EventLog

Use the XenDesktop_EventLog Knowledge Script to monitor the Windows Application event log and custom Citrix logs for Citrix XenDesktop or XenApp error or warning events. You can specify a list of event sources, event categories, or event ID to ignore in the event log search.

This script raises an event if the Windows Application event log entries match your search criteria.

88.3.1 Resource Objects

Citrix XenDesktop or XenApp site object

88.3.2 Default Schedule

The default schedule is every 15 minutes.

88.3.3 Setting Parameter Values

Set the following parameters on the **Values** tab as needed:

Description	How to Set It
General Settings	
Job failure event notification	
Event severity when job fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the EventLog job fails. The default is 5.
Monitor Windows Event Log	
Event Notification	
Comma-separated list of event sources to ignore	Specify the location of the path that contains the list of event sources to ignore. Click the **Ellipsis** (...) button to navigate to the file.
Comma-separated list of event categories to ignore	Specify the location of the path that contains the list of event categories to ignore. Click the **Ellipsis** (...) button to navigate to the file.
Comma-separated list of event IDs to ignore	Specify the location of the path that contains the list of event IDs to ignore. Click the **Ellipsis** (...) button to navigate to the file.
Raise event if XenDesktop error events are found?	Select **Yes** to raise an event when the script encounters XenDesktop or XenApp error events. The default is Yes.
Event severity when XenDesktop error events are found	Set the event severity level, from 1 to 40, to indicate the importance of the event in which the script encounters XenDesktop or XenApp error events. The default is 10.
Raise event if XenDesktop warning events are found?	Select **Yes** to raise an event when the script encounters warning events. The default is Yes.
Event severity when XenDesktop warning events are found	Set the event severity level, from 1 to 40, to indicate the importance of the event in which the script encounters warning events. The default is 20.

88.4 LicenseStatus

Use the XenDesktop_LicenseStatus Knowledge Script to monitor the license usage and license expiration of XenDesktop or XenApp servers.

This script raises an event when the percentage of licenses in use exceeds a threshold you set, or if the license expiration date is approaching. You can also choose to collect data for the number of licenses in use.

88.4.1 Resource Objects

Citrix XenDesktop or XenApp License Server object

88.4.2 Default Schedule

The default schedule is daily.

88.4.3 Setting Parameter Values

Set the following parameters on the **Values** tab as needed:

Description	How to Set It
General Settings	
Job failure event notification	
Event severity when job fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the LicenseStatus job fails. The default is 5.
Monitor License Usage	
Event Notification	
Raise event if percentage of licenses in use exceeds threshold?	Select **Yes** to raise an event if the percentage of licenses in use exceeds the threshold. The default is Yes.
Threshold - Maximum percentage of licenses in use	Specify the maximum percentage of licenses in use that can exist before an event is raised. The default is 80%.
Event severity when maximum percentage of licenses in use is exceeded	Set the event severity level, from 1 to 40, to indicate the importance of the event in which the percentage of licenses in use exceeds the threshold. The default is 10.
Data Collection	
Collect data for number of licenses in use?	Select **Yes** to collect data for the number of licenses in use. The default is unselected.
Collect data for percentage of licenses in use?	Select **Yes** to collect data for the percentage of licenses in use. The default is unselected.
Monitor License Expiration	
Event Notification	
Raise event if license expiration date is approaching?	Select **Yes** to raise an event if the license expiration date is approaching. In the following parameter, you can specify when you want to raise the event based on the number of days before the license expires. The default is Yes.

Description	How to Set It
Threshold - Number of days before license expires	Specify the number of days before the license expires, at which point an event is raised. The default is 5 days.
Event severity when number of days before license expires is reached	Set the event severity level, from 1 to 40, to indicate the importance of the event in which the number of days before the license expires is reached. The default is 15.

88.5 MachineFailures

Use the XenDesktop_MachineFailures Knowledge Script to monitor the number and type of failures that have occurred on machines in delivery groups on a XenDesktop or XenApp server. You can filter the monitoring based on failure type or whether the failure occurred for a single-user session or multi-user session.

This script raises an event when the number of machine failures exceed a threshold you set, and you can collect data on the number and type of machine failures.

88.5.1 Resource Objects

Citrix XenDesktop or XenApp Delivery Group object

88.5.2 Default Schedule

The default schedule is every 15 minutes.

88.5.3 Setting Parameter Values

Set the following parameters on the **Values** tab as needed:

Description	How to Set It
General Settings	
Job failure event notification	
Event severity when job fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the MachineFailures job fails. The default is 5.
Monitor Machine Failures	
Filters	
Sessions to Monitor	
Single-user (desktop OS) sessions	Select **Yes** to monitor single-user, or desktop operating system, sessions. The default is Yes.
Multi-user (server OS) sessions	Select **Yes** to monitor multi-user, or server operating system, sessions. The default is Yes.
Failure Types to Monitor	
Machine failed to start	Select **Yes** to monitor when a server failed to start. The default is Yes.
Machine stuck on boot	Select **Yes** to monitor when a server begins to reboot but never completes the process. The default is Yes.
Machine is unregistered	Select **Yes** to monitor when a server is unregistered. The default is Yes.
Machine is at maximum capacity	Select **Yes** to monitor when a server is at maximum capacity. The default is Yes.

Description	How to Set It
Event Notification	
Raise event if number of machine failures exceeds threshold?	Select **Yes** to raise an event if the number of server failures exceeds a threshold you set. The default is Yes.
Threshold - Maximum number of machine failures	Specify the maximum number of server failures that can exist before an event is raised. The default is 0 failures.
Event severity when maximum number of failures is exceeded	Set the event severity level, from 1 to 40, to indicate the importance of the event in which the maximum number of failures is exceeded. The default is 10.
Data Collection	
Collect data for number of machine failures?	Select **Yes** to collect data for the number of server failures. The default is unselected.

88.6 MachineRegistration

Use the XenDesktop_MachineRegistration Knowledge Script to monitor the registration state of servers running Citrix XenDesktop or XenApp.

This script raises an event when a server remains in the Unregistered, Initializing, or AgentError states for longer than the thresholds you set.

NOTE: The XenDesktop_MachineRegistration script only monitors machines with a power state of On. The script ignores machines that are powered off or in other states, including servers that are in maintenance mode. This script also does not monitor servers that are configured as remote servers, as opposed to server operating system servers or desktop operating system servers, which are the types this script monitors.

88.6.1 Resource Objects

Citrix XenDesktop or XenApp Delivery Group object or Catalog object

88.6.2 Default Schedule

The default schedule is every 5 minutes.

88.6.3 Setting Parameter Values

Set the following parameters on the **Values** tab as needed:

Description	How to Set It
General Settings	
Job failure event notification	
Event severity when job fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the MachineRegistration job fails. The default is 5.
Monitor Machines in Unregistered State	
Event Notification	
Raise event if a machine is in the Unregistered state?	Select **Yes** to raise an event if a machine is in the Unregistered state. The default is Yes.
Threshold - Maximum amount of time for a machine to remain in the Unregistered state	Specify the maximum amount of time for a machine to remain in the Unregistered state before an event is raised. The default is 0 minutes.
Event severity when a machine is found to be in the Unregistered state	Set the event severity level, from 1 to 40, to indicate the importance of the event in which a machine is found to be in the Unregistered state. The default is 5.
Monitor Machines in Initializing State	
Event Notification	
Raise event if a machine is in the Initializing state?	Select **Yes** to raise an event if a machine is in the Initializing state. The default is Yes.

Description	How to Set It
Threshold - Maximum amount of time for a machine to remain in the Initializing state	Specify the maximum amount of time for a machine to remain in the Initializing state before an event is raised. The default is 0 minutes.
Event severity when a machine is found to be in the Initializing state	Set the event severity level, from 1 to 40, to indicate the importance of the event in which a machine is found to be in the Initializing state. The default is 5.
Monitor Machines in AgentError State	
Event Notification	
Raise event if a machine is in the AgentError state?	Select **Yes** to raise an event if a machine is in the AgentError state. The default is Yes.
Threshold - Maximum amount of time for a machine to remain in the AgentError state	Specify the maximum amount of time for a machine to remain in the AgentError state before an event is raised. The default is 0 minutes.
Event severity when a machine is found to be in the AgentError state	Set the event severity level, from 1 to 40, to indicate the importance of the event in which a machine is found to be in the AgentError state. The default is 5.

88.7 ServiceStatus

Use the XenDesktop_ServiceStatus Knowledge Script to monitor the status of XenDesktop services. This script raises an event when services are not running and when stopped services fail to start.

If you are monitoring multiple services, separate events are raised for each service. The same thresholds apply to all services.

The XenDesktop_ServiceStatus script runs a series of connectivity tests on a sub-set of the XenDesktop services that use back-end databases. The script runs connectivity tests on the following XenDesktop services:

- Citrix AD Identity Service
- Citrix Broker Service
- Citrix Configuration Service
- Citrix Configuration Logging Service
- Citrix Delegated Administration Service
- Citrix Environment Test Service
- Citrix Host Service
- Citrix Machine Creation Service
- Citrix Monitor Service
- Citrix Storefront Service

88.7.1 Resource Objects

Citrix XenDesktop Service Folder object or Service object

88.7.2 Default Schedule

The default schedule is every 5 minutes.

88.7.3 Setting Parameter Values

Set the following parameters on the **Values** tab as needed:

Description	How to Set It
General Settings	
Job failure event notification	
Event severity when job fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the ServiceStatus job fails. The default is 5.
Monitor Status of XenDesktop Services	
Services to be Monitored	

Description	How to Set It
Monitor services configured to start automatically?	Select **Yes** to monitor the XenDesktop or XenApp services that start automatically. The default is Yes.
Monitor services configured to start manually?	Select **Yes** to monitor the XenDesktop or XenApp services that must be manually started. The default is unselected.
Event Notification	
Raise event if XenDesktop services are not running?	Select **Yes** to raise an event when the XenDesktop or XenApp services are not running. The default is Yes.
Event severity when services are not running	Set the event severity level, from 1 to 40, to indicate the importance of the event in which the XenDesktop or XenApp services are not running. The default is 10.
Start services not currently running?	Select **Yes** to start any XenDesktop or XenApp services that are not currently running. The default is Yes.
Threshold - Timeout for service startup	Specify the length of time in seconds that the job should wait for a service to start before timing out and raising a failure event. The default timeout is 60 seconds.
Raise event if stopped services fail to start?	Select **Yes** to raise an event when any stopped services fail to start. The default is Yes.
Event severity when stopped services fail to start.	Set the event severity level, from 1 to 40, to indicate the importance of the event in which the stopped services fail to start. The default is 5.
Monitor XenDesktop Service Database Connections	
Event Notification	
Raise event if a connection cannot be made to a service database?	Select **Yes** to raise an event when the module cannot connect to a service database. The default is Yes.
Event severity when a connection cannot be made to a service database	Set the event severity level, from 1 to 40, to indicate the importance of the event in which the module could not connect to a service database. The default is 10.

88.8 Sessions

Use the XenDesktop_Sessions Knowledge Script to monitor the status and number of sessions that exist on a XenDesktop or XenApp server on a total and per-server basis.

You can filter the number of servers to monitor by matching tags or metadata, and you can also filter the sessions by session states. You can also collect data on the maximum and average number of sessions on XenDesktop or XenApp servers, and total number of sessions on all XenDesktop or XenApp servers.

You can run this script on server catalogs or delivery groups. In many cases, a server belongs to both a catalog and a delivery group. If a server appears in a delivery group, it will be a member of a catalog as well. If a threshold event is raised for a server, and that server exists in both a catalog and a delivery group being monitored, the module raises two events: one event on the delivery group and one event on the catalog. As a result, some events might be duplicated. To avoid duplicate events, run the job only on delivery groups or only on catalogs, instead of on both objects.

88.8.1 Resource Objects

Citrix XenDesktop or XenApp Delivery Group object or Catalog object

88.8.2 Default Schedule

The default schedule is every 15 minutes.

88.8.3 Setting Parameter Values

Set the following parameters on the **Values** tab as needed:

Description	How to Set It
General Settings	
Job failure event notification	
Event severity when job fails	Set the severity level, from 1 to 40, to indicate the importance of an event in which the Sessions job fails. The default is 5.
Monitor Machine Sessions	
Machine Filters	

Description	How to Set It
Include only machines with matching tags or metadata?	Select **Yes** to filter the list of sessions to monitor based on machines with matching tags (name) or metadata (name=value). The default is unselected. In XenDesktop or XenApp you can associate tags and metadata with specific servers. A *tag* is simply a name, while a *metadata* item consists of a name and a value that you can specify in the following manner: `tag1, tag2,md1name=md1value , tag3, md1name = md2value, md2name =md2value` The script ignores and spaces around the commas and equal signs in the metadata item. Also, in this example the metadata name `md1name` is used twice, with two different values. This combination is valid, and it matches all sessions whose associated machines have either value for that metadata name. The script ignores duplicate entries for tags and metadata where both the name and value are duplicated. **Tips** • If you specify only tags, the script monitors sessions associated with, and only with, any server that has any of those tags. • If you specify only metadata items, the script only monitors sessions associated with servers that have a matching metadata item (name and value). • If you specify *both* tags and metadata, the script monitors only sessions associated with servers that match at least one of the tags, and the script will also monitor at least one of the metadata items. In other words, the script monitors only sessions associated with machines that have a matching tag *and* a matching metadata item.
List of machines by tag (name) or metadata (name=value) to monitor	Specify the XenDesktop or XenApp servers that you want to monitor, based on tag (name) or metadata (name=value). Separate the server names with commas.
Include only machines in the following states?	Select **Yes** to filter the list of sessions to monitor based on one or more of the following set of session states. The default is Yes.
PreparingSession	Select **Yes** to filter the list of sessions to include sessions with the PreparingSession tag or metadata. The default is Yes.
Connected	Select **Yes** to filter the list of sessions to include sessions with the Connected tag or metadata. The default is Yes.
Active	Select **Yes** to filter the list of sessions to include sessions with the Active tag or metadata. The default is Yes.
Disconnected	Select **Yes** to filter the list of sessions to include sessions with the Disconnected tag or metadata. The default is Yes.
Reconnecting	Select **Yes** to filter the list of sessions to include sessions with the Reconnecting tag or metadata. The default is Yes.
NonBrokeredSession	Select **Yes** to filter the list of sessions to include sessions with the NonBrokeredSession tag or metadata. The default is Yes.
Unknown	Select **Yes** to filter the list of sessions to include sessions with the Unknown tag or metadata. The default is Yes.

Description	How to Set It
Other	Select **Yes** to filter the list of sessions to include sessions with the Other tag or metadata. The default is Yes.
Monitor Sessions Per Machine	
Event Notification	
Raise event if number of sessions on any machine exceeds threshold?	Select **Yes** to raise an event when the number of sessions on any XenDesktop or XenApp server exceeds a threshold you set. The default is Yes.
Threshold - Maximum number of sessions on any machine	Specify the maximum number of sessions that can exist on any machine before an event is raised. The default is 10 sessions.
Event severity when services are not running	Set the event severity level, from 1 to 40, to indicate the importance of the event in which the XenDesktop or XenApp services are not running. The default is 10.
Data Collection	
Collect data for maximum number of sessions on any machine?	Select **Yes** to collect data for the maximum number of sessions on any XenDesktop or XenApp server. The default is unselected.
Collect data for average number of sessions per machine?	Select **Yes** to collect data for the average number of sessions per XenDesktop or XenApp server. The default is unselected.
Monitor Total Number of Sessions	
Event Notification	
Raise event if total number of sessions exceeds threshold?	Select **Yes** to raise an event when the total number of sessions exceeds a threshold you set. The default is Yes.
Threshold - Maximum number of sessions	Specify the maximum number of sessions that can exist on all XenDesktop or XenApp servers before an event is raised. The default is 75 sessions.
Event severity when number of sessions exceeds threshold	Set the event severity level, from 1 to 40, to indicate the importance of the event in number of sessions exceeds the threshold. The default is 10.
Data Collection	
Collect data for total number of sessions?	Select **Yes** to collect data for the total number of sessions on a XenDesktop or XenApp server. The default is unselected.
