About this Book and the Library

The *Identity Manager Driver for Office 365 and Azure Active Directory Implementation Guide* explains how to install and configure the Identity Manager Driver for Azure Active Directory.

Intended Audience

This book provides information for administrators implementing Identity Manager, application server developers, Web services administrators, and consultants.

Other Information in the Library

The library provides the following information resources:

**Identity Manager Setup Guide**

Provides overview of Identity Manager and its components. This book also provides detailed planning and installation information for Identity Manager.

**Designer Administration Guide**

Provides information about designing, testing, documenting, and deploying Identity Manager solutions in a highly productive environment.

**User Application: Administration Guide**

Describes how to administer the Identity Manager User Application.

**User Application: User Guide**

Describes the user interface of the Identity Manager User Application and how you can use the features it offers, including identity self-service, the Work Dashboard, role and resource management, and compliance management.

**User Application: Design Guide**

Describes how to use the Designer to create User Application components, including how to work with the Provisioning view, the directory abstraction layer editor, the provisioning request definition editor, the provisioning team editor, and the role catalog.

**Identity Reporting Module Guide**

Describes the Identity Reporting Module for Identity Manager and how you can use the features it offers, including the Reporting Module user interface and custom report definitions, as well as providing installation instructions.

**Analyzer Administration Guide**

Describes how to administer Analyzer for Identity Manager.

**Identity Manager Common Driver Administration Guide**

Provides information about administration tasks that are common to all Identity Manager drivers.
Identity Manager Driver Guides

Provides implementation information about Identity Manager drivers.

About NetIQ Corporation

We are a global, enterprise software company, with a focus on the three persistent challenges in your environment: Change, complexity and risk—and how we can help you control them.

Our Viewpoint

Adapting to change and managing complexity and risk are nothing new

In fact, of all the challenges you face, these are perhaps the most prominent variables that deny you the control you need to securely measure, monitor, and manage your physical, virtual, and cloud computing environments.

Enabling critical business services, better and faster

We believe that providing as much control as possible to IT organizations is the only way to enable timelier and cost effective delivery of services. Persistent pressures like change and complexity will only continue to increase as organizations continue to change and the technologies needed to manage them become inherently more complex.

Our Philosophy

Selling intelligent solutions, not just software

In order to provide reliable control, we first make sure we understand the real-world scenarios in which IT organizations like yours operate—day in and day out. That's the only way we can develop practical, intelligent IT solutions that successfully yield proven, measurable results. And that's so much more rewarding than simply selling software.

Driving your success is our passion

We place your success at the heart of how we do business. From product inception to deployment, we understand that you need IT solutions that work well and integrate seamlessly with your existing investments; you need ongoing support and training post-deployment; and you need someone that is truly easy to work with—for a change. Ultimately, when you succeed, we all succeed.

Our Solutions

- Identity & Access Governance
- Access Management
- Security Management
- Systems & Application Management
- Workload Management
- Service Management
Contacting Sales Support

For questions about products, pricing, and capabilities, contact your local partner. If you cannot contact your partner, contact our Sales Support team.

Contacting Documentation Support

Our goal is to provide documentation that meets your needs. The documentation for this product is available on the NetIQ Web site in HTML and PDF formats on a page that does not require you to log in. If you have suggestions for documentation improvements, click Add Comment at the bottom of any page in the HTML version of the documentation posted at www.netiq.com/documentation. You can also email Documentation-Feedback@netiq.com. We value your input and look forward to hearing from you.

Contacting the Online User Community

NetIQ Communities, the NetIQ online community, is a collaborative network connecting you to your peers and NetIQ experts. By providing more immediate information, useful links to helpful resources, and access to NetIQ experts, NetIQ Communities helps ensure you are mastering the knowledge you need to realize the full potential of IT investments upon which you rely. For more information, visit community.netiq.com.
About This Guide

This guide explains how to install and configure the Identity Manager Driver for Office 365 and Azure Active Directory. The guide includes the following information:

- Chapter 1, "Understanding the Office 365 and Azure Active Directory Driver," on page 11
- Chapter 2, "Installing the Driver Files," on page 17
- Chapter 3, "Creating a New Driver Object," on page 27
- Chapter 4, "Upgrading an Existing Driver," on page 35
- Chapter 5, "Securing Driver Communication," on page 39
- Chapter 6, "Transitioning from Existing Office 365 Driver to New Azure AD Driver," on page 43
- Chapter 7, "Understanding Identity Manager Exchange Service," on page 45
- Chapter 8, "Troubleshooting," on page 47
- Appendix A, "Driver Properties," on page 53
- Appendix B, "Known Issues and Limitations," on page 65

Audience

This guide is intended for administrators implementing Identity Manager, application server developers, Web services administrators, and consultants.

Feedback

We want to hear your comments and suggestions about this manual and the other documentation included with this product. Please use the User Comments feature at the bottom of each page of the online documentation, or go to www.novell.com/documentation/feedback.html and enter your comments there.

Documentation Updates

For the most recent version of this document, see the Identity Manager Drivers Documentation Web site (http://www.netiq.com/documentation/idm45drivers/index.html).

Additional Documentation

For information on Identity Manager, see the Identity Manager Documentation Web site (http://www.netiq.com/documentation/idm45drivers).
Understanding the Office 365 and Azure Active Directory Driver

The Identity Manager Driver for Office 365 and Azure Active Directory (Azure AD driver) allows you to seamlessly provision and deprovision users, group memberships, exchange mailboxes, roles, and licenses to Azure AD cloud. You can also configure the driver to integrate with Identity Manager Service for Exchange Online (Identity Manager Exchange Service) for synchronizing Office 365 attributes.

In general, you can perform the following tasks by using the driver:

- Synchronize users and groups on Publisher and Subscriber channels
- Provision and deprovision mail and mailbox users, distribution and mail enabled security groups
- Assign and revoke roles, group membership, and licenses using entitlements
- Extend the Azure AD schema
- Synchronize passwords from the Identity Vault

This section contains high-level conceptual information about the Azure AD driver.

- “Understanding How the Driver Works” on page 11
- “Data Transfers Between Systems” on page 13
- “Driver Features” on page 13
- “Planning to Install the Driver” on page 15

Understanding How the Driver Works

The following figure shows the data flow between Identity Manager and the Azure AD driver:

Azure AD Driver

The Azure AD driver allows you to seamlessly provision and deprovision users, group memberships, exchange mailboxes, roles, and licenses to Azure AD (cloud). The driver synchronizes the user identity information between the Identity Vault and Azure AD and keeps this information consistent at all times.
Identity Manager Service for Exchange Online

The Azure AD driver uses the Identity Manager Exchange Service to provision or deprovision user mailboxes, mail users, create or remove distribution lists and security groups on Office 365 Exchange Online. For more information on configuring the service, see Chapter 7, “Understanding Identity Manager Exchange Service,” on page 45.

PowerShell

The Azure AD driver uses PowerShell for executing Exchange operations such as creation of Exchange mailbox, mail users, and groups.

Internet Protocols

The Azure AD driver uses the following Internet protocols to exchange data between Identity Manager and Azure AD.

- **REST (Representational State Transfer):** An HTTP-based protocol for exchanging messages over the network. It supports POST, PUT, GET, PATCH, DELETE methods to communicate with the application logic.

- **HTTPS (Hypertext Transfer Protocol):** An HTTP protocol over SSL (Secure Socket Layer) as a sub-layer under the regular HTTP application layering. HTTPS encrypts and decrypts user page requests as well as the pages that are returned by the web server.

Azur AD processes a request and returns a REST response to the driver shim. The shim receives the response as an array of bytes and converts it to an XML document before passing it back to the driver policies. The input transformation style sheet processes the response and converts it into appropriate XDS that is reported back to the Identity Manager engine.

Identity Manager Engine

The Identity Manager engine uses XDS, a specialized form of XML (Extensible Markup Language), to represent events in the Identity Vault. Identity Manager passes the XDS to the driver policy which can consist of basic policies, DirXML Script, and XSLT (Extensible Stylesheet Language Transformation) style sheets. The Azure AD driver uses REST protocol to handle the HTTP transport of data between the Identity Vault and Azure AD.

The Subscriber channel receives XDS command documents from the Identity Manager engine, converts them to Azure AD API (Application Program Interface) calls, and executes them. The driver shim translates the XDS to XML payload on the Subscriber channel and then invokes the appropriate REST endpoints exposed by Azure AD for Object CRUD (Create, Read, Update, and Delete) operations.

Remote Loader

A Remote Loader enables a driver shim to execute outside of the Identity Manager engine, remotely on a different machine. The Remote Loader passes the information between the shim and the Identity Manager engine.

For the Azure AD driver, you can choose to install the driver shim on the server where the Remote Loader is running.
Data Transfers Between Systems

The Azure AD driver supports data transfer on the Publisher and the Subscriber channels.

The Publisher channel controls the data transfer as follows:

- Reads events from the configured domains.
- Submits that information to the Identity Vault.

The Subscriber channel controls the data transfer as follows:

- Watches for the events from the Identity Vault objects.
- Makes changes to Azure AD based on the event data.

You can configure the driver filter to allow both Azure AD and Identity Vault to modify the attribute(s). In this configuration, the most recent change determines the attribute value, except for merge operations that are controlled by filters and the merge authority.

The Exchange schema uses a different casing than the Azure AD schema where the first character of an Exchange schema attribute is uppercase, which is lowercase in Azure AD schema.

Driver Features

The Azure AD driver supports the following features:

- “Supported Operations” on page 13
- “Schema Extension” on page 14
- “License Handling” on page 14
- “Hybrid Mode” on page 14
- “Entitlements” on page 15

Supported Operations

By default, the Azure AD driver synchronizes user and group objects, and Exchange mailboxes. You can customize the driver to synchronize additional classes and attributes.

The driver supports the following operations on the Publisher channel:

- Add, Modify, Delete, and Query operations.
- Migrate operation only through Azure AD attributes. Exchange attributes are not supported for migration.

The following Exchange groups can be added through the Publisher channel:

- Office 365 Group
- Distribution Group
- Security Group

NOTE: You need to write a policy to set a value for Equivalent to Me while modifying a group membership.
The driver supports the following operations on the Subscriber channel:

- Add, Modify, Delete, Migrate, and Query operations on users and groups.
- Add or delete licenses only on user objects.
- Set or reset a password only on user objects.
- Execute PowerShell cmdlets using policies.
- Assign or revoke roles and licenses in hybrid mode.

The following Exchange groups can be added through the Subscriber channel:

- Distribution Group
- Security Group

Schema Extension

The Azure AD driver allows you to extend the Azure AD schema to include different types of attributes such as Integer, Boolean, and String using the driver parameters. For example, you can add, remove, or change extension attributes on a user or a group class with the allowed attribute types. For more information, see the Microsoft website.

License Handling

In the Office 365 driver, you created custom licenses to disable specific service plans. For example, to disable Office 365 ProPlus from your enterprise plan, you specified this string in the driver configuration: OFFICESUBSCRIPTION. For more information, see the NetIQ Identity Manager Driver for Office 365 Implementation Guide.

In the Azure AD driver, license handling is simplified. The driver lists all the available service plans for your subscription in Catalog Administrator. Each service plan can be individually assigned or revoked for a user through the License Entitlement resource. For example, if you want to assign only Office 365 ProPlus to a user, select OFFICESUBSCRIPTION from the list of service plans. The driver also supports assigning or revoking multiple plans to a user.

Hybrid Mode

The following figure shows the hybrid mode deployment scenario:

In this deployment, Azure AD Connect integrates on-premise Active Directory with Azure Active Directory. Azure Active Directory does not allow modifications on user and group objects that were synchronized through Azure AD Connect. However, it allows you to provision roles and licenses to
the users. To accomplish this, you must deploy an Azure AD driver in hybrid mode. To synchronize identities from the Identity Vault to on-premise Active Directory, you must have an AD driver in your environment.

**NOTE:** If you have upgraded to the 5.0.1 version of the driver, the group membership entitlement and exchange role entitlement are supported in hybrid mode. For more information on entitlements supported in 5.0.1, see What’s New in Version 5.0.1?.

To provision roles and licenses, set the driver in hybrid mode in Designer or iManager. For more information, see “Configuring the Driver” on page 32.

The driver performs the following actions when operating in hybrid mode:

- When a user is provisioned to AD through AD driver's user account entitlements and the user is synchronized to Azure AD through Azure AD Connect, the driver updates the user association in the Identity Vault.
- When a user is deleted from Azure AD, the driver removes the association for the user from the Identity Vault.
- When a user is granted or revoked roles or licenses through entitlements, the driver grants or revokes roles or licenses after an association is created for the user.
- When an account entitlement is revoked for a user in AD, the driver removes the association for the user from the Identity Vault.

**NOTE:** You cannot add users, delete users, and modify user attributes through the publisher channel when you operate the Azure AD driver in hybrid mode. However, the Azure AD driver will update the associations accordingly.

In hybrid mode, the AD driver's account tracking takes precedence over Azure AD driver. The password synchronization to the Identity Vault is handled by AD driver in hybrid mode.

**Entitlements**

The Azure AD driver supports entitlements. By default, it supports UserAccount, Group, Licenses, and Roles entitlements.

When using entitlements, an action such as provisioning an account in the target directory is delayed until the proper approvals have been made. In Role-Based Services, rights assignments are made based on attributes of a user object. Entitlements standardize a method of recording this information on objects in the Identity Vault. From the driver perspective, an entitlement grants or revokes the right to resources in Azure AD. You can use entitlements to grant the rights to an account in Azure AD, to control group membership, roles, and licenses.

**Planning to Install the Driver**

This section provides information for planning the installation and configuration for the driver.

- “Installation Requirements” on page 16
- “Options for Installing the Driver Shim” on page 16
Installation Requirements

The Azure AD driver requires the following applications and files:

- Identity Manager 4.5.5 or later, particularly the following components:
  - Designer 4.5.5.1 or later
  - Remote Loader 4.5.5 or later (if you want to connect through the Remote Loader)
  - REST driver 1.0.0.1 (if you install the Azure AD driver on Identity Manager 4.5.5). Download and install the patch from NetIQ Integration Module for Tools 4.6.
- Driver Set packages
  - Advanced Java Class
  - Common Settings
  - Identity Manager Default Universal Password Policy
- Azure AD driver files
  - NIdM_Driver_4.5_O365_AzureAD.zip
- Azure AD driver packages (1.0.0)
  - Azure AD Base
  - Azure AD Default
  - Azure AD Exchange Default
  - Azure AD PasswordSync
  - Azure AD Audit Entitlements
  - Azure AD Cloud Only Entitlements
  - Azure AD Hybrid Entitlements
  - Azure AD Account Tracking
  - Azure AD Data Collection
  - Azure AD Managed System Information

Options for Installing the Driver Shim

You can install the driver shim on the Identity Manager server or the Remote Loader server.

For more information about the platforms supported with Identity Manager or the Remote Loader, see one of the following sections in the NetIQ Identity Manager Setup Guide.

- System Requirements for the Identity Manager Engine
- System Requirements for the Remote Loader

The Remote Loader loads the driver and communicates with the Identity Manager engine on behalf of the driver installed on the remote server. For information about configuring the Identity Manager drivers with the Remote Loader, see Configuring the Remote Loader and Drivers in the NetIQ Identity Manager Setup Guide.
Installing the Driver Files

You can install the Azure AD driver on the Identity Manager server or with the Remote Loader.

Preparing for Installation

This section provides the prerequisites, considerations, and system setup needed to install the driver:

- “Prerequisites for Driver” on page 17
- “Prerequisites for Identity Manager Exchange Service” on page 17
- “Prerequisites for OAuth 2.0” on page 18
- "Preparing to Install the Driver on Identity Manager 4.5.5" on page 22

Prerequisites for Driver

The driver requires the following applications and files, at a minimum:

Installing the Driver with Identity Manager 4.5.5

- Identity Manager REST driver 1.0.0.1 or later. Download and install the patch from NetIQ Integration Module for Tools 4.6.
- Identity Manager Office 365 and Azure AD driver
- Identity Manager Designer 4.5.5.1 or later

Installing the Driver with Identity Manager 4.6

- Identity Manager REST driver
- Identity Manager Office 365 and Azure AD driver
- Identity Manager Designer 4.6

Prerequisites for Identity Manager Exchange Service

- Microsoft Windows Management Framework 4.0 (required for Windows Server 2008 R2)
- Microsoft .NET Framework Version 4.5 or later

**NOTE:** You need to additionally install Microsoft .NET Framework 4.5 on Windows Server 2008 R2.

- Microsoft Visual C++ 2012 Redistributable packages

For installing instructions, visit the Microsoft [download page](#).
Installing the Driver Files

- Microsoft Online Services Sign-In Assistant version 7.250.4556.0 and later
- Windows Azure AD Module for Windows PowerShell on the computer where you will install Windows Powershell service. Click **Windows Azure Active Directory Module for Windows PowerShell (64-bit version)** from this page.

Identity Manager Exchange Service can be run on a user configured port. However, the service cannot be used with any other REST client tools.

**Prerequisites for OAuth 2.0**

The driver uses OAuth 2.0 protocol to authenticate to Azure AD. To support this protocol for authentication, you need to have a proxy application for the Azure AD driver on Azure AD. The Client ID and Client Secret allotted to the application will be later used in the Azure AD driver configuration. For more information about Azure Active Directory Application Proxy, see Microsoft Azure documentation.

**Creating a Proxy Application on Azure AD**

1. Log in to the Azure portal. For example, https://manage.windowsazure.com or https://portal.azure.com. In this section, we have used https://manage.windowsazure.com as an example.
2. Select **Active Directory** from the left pane of the portal.
3. Select the default Active Directory from the right pane of the portal.
4. Click **Applications**.
5 Click Add.

6 On the What you want to do page, click Add an application my organization is developing.

7 On the Add Application page, specify a name for your application and select Web Application And/Or Web API. For example, AzureADDriver
Specify the following in the Add Application page:

- **Sign-on URL**: Specify a URL for the users to sign in and use the application. For example, http://localhost.
- **App ID URI**: Specify a URI that Azure AD can use for the application you created. For example, http://localhost.

Now your application is created.

9 Click **Configure**.

10 Copy and take a note of the **Client ID** for your application. You will need this value later for configuring the driver.

For information about configuring the **Client ID**, see Step 9 of the **Installing the Driver Packages** section.
11 Under the **Keys** section, select a duration for the validity of your password.

12 Click **Save** to create the key for your application.

The key is **Client Secret** for your application. For information about configuring the **Client Secret**, see Step 9 of **Installing the Driver Packages** section.

**IMPORTANT:** Copy and take a note of the **Client Secret**. You cannot retrieve the **Client Secret** at a later point.

### Assigning the Rights to the Application

1 Log in to PowerShell and connect to the Office 365 Exchange Online service by using the following command:

```powershell
Connect-MSolService
```

2 To obtain the Client ID for your application, replace `<AppPrincipalId>` with the Client ID that you obtained in Step 10 from “Creating a Proxy Application on Azure AD” on page 18 and run the following commands in PowerShell.

```powershell
Get-MsolServicePrincipal | ft DisplayName, <AppPrincipalId> -AutoSize

$ClientIdWebApp = '<AppPrincipalId>'

$webApp = Get-MsolServicePrincipal -AppPrincipalId $ClientIdWebApp
```

3 Assign the **Company Administrator** rights to your application using the Client ID obtained in Step 2 by running the following command:

```powershell
Add-MsolRoleMember -RoleName "Company Administrator" -RoleMemberType ServicePrincipal -RoleMemberObjectId $webApp.ObjectID
```

The **Company Administrator** role will give you rights to delete the directory objects.

### Preparing to Install the Driver on Identity Manager 4.5.5

Before installing the driver files, perform the following actions in the Identity Manager installation directory in one of the following locations:

**Linux:** `/opt/novell/eDirectory/lib/dirxml/classes`
Windows: C:\Novell\IdentityManager\NDS\lib

1. Delete the j2eevalidate.jar.
2. Back up the commons-codec-1.3.jar file.
3. Delete all versions of httpClient.jar and httpcore.jar files except the following files:
   - httpClient-4.4.1.jar
   - httpcore-4.4.1.jar
4. Replace commons-codec-1.3.jar with commons-codec-1.6.jar.
   The commons-codec-1.6.jar is located in the lib folder of the NIdM_Driver_4.5_O365_AzureAD.zip file.
5. Restart eDirectory.
6. Extend the eDirectory schema manually to include the new attributes for supporting Office 365 Exchange Online. You must perform an eDirectory health check to ensure that the tree is ready to accept the new schema.
   To extend the schema, use the ndssch utility.
   For example,
   /opt/novell/eDirectory/bin/ndssch -h <engine server> <admin.sa.system> ../lib/nds-schema/dvr_ext.sch
   novell-DXXMLsch-<version>.rpm contains the dvr_ext.sch schema file that includes the necessary changes for the driver.
   The schema file can be found at the following location in the Identity Manager 4.5.5 directory:
   cd-image\patch\Windows\engine\64-bit\dvr_ext.sch

Installing the Driver and the Identity Manager Exchange Service

The driver installation program guides you through the driver and the Identity Manager Exchange Service installation.

1. Download the NIdM_Driver_4.5_O365_AzureAD.zip file from the Download website.
2. Unzip the file.
3. Navigate to the installation folder and run the following depending on your platform:
   - Linux: install.bin
   - Windows: install.exe
4. Click Next.
5. On the Choose Install Set page, select the appropriate components based on your requirement:
   - All: Select this option to install the driver and the Identity Manager Exchange Service.
   - Identity Manager Driver for Microsoft Office 365 and Azure AD: Select this option to install the driver.
   - Identity Manager Service for Exchange Online: Select this option to install the Identity Manager Exchange Service.
6. On the Identity Manager Service for Exchange Online page, fill in the following fields to install the Identity Manager Exchange Service and then click Next:
   - Install folder: Specify the path to install the Identity Manager Exchange Service.
• **Port:** Specify the port for the Identity Manager Exchange Service to run.

• **Certificate Alias:** Specify the alias for the server certificate. You must specify this value for **Nickname** while configuring SSL for this service. For more information see [Step 1 on page 39](#).

7 On the **Install the Driver** page, select **Identity Manager Server** or **Remote Loader**, based on where you want to install the driver. If you select **Remote Loader**, you need to specify the path for Remote Loader installation.

8 Click **Next**.

9 Click **Install**.

**NOTE:** By default, Identity Manager Exchange Service is stopped. For information about starting the service, see “Verifying and Starting the Identity Manager Exchange Service” on page 24.

10 For driver installation, click **Restart the Identity Manager Server** and click **Next**.

This step is not required for installing the Exchange service.

NetIQ recommends you to use TLS 1.1 and TLS 1.2 protocols with the Identity Manager Exchange Service. If you are using ciphers and protocols such as RC4 and Triple DES, or SSLv2/v3 on a server running Identity Manager Exchange Service, you must disable them using the `disableWeakCiphers.reg` file provided in the Exchange Service installation directory. You can either execute the registry file or import the file into Windows Registry. After the changes are made, restart the server. For more information about restricting the use of certain cryptographic algorithms and protocols on Windows servers, see [Microsoft Support Site](#).

### Verifying and Starting the Identity Manager Exchange Service

After finishing the installation of Identity Manager Exchange Service, verify that the service is properly installed.

**NOTE:** Ensure that SSL is configured for the Identity Manager Exchange Service before starting the service. This is a mandatory step before running the service. For more information, see [Securing Communication with Identity Manager Exchange Service](#).

1 From the **Start** menu, type `regedit`.

2 On the **Registry Editor** page, locate the service at `HKEY_LOCAL_MACHINE > Software > Novell > ExchServer` and verify that the Port and CertificateFriendlyName have the correct values.

   The CertificateFriendlyName must be the same as Certificate Alias that you specified in step 6 of **Installing the Driver** and the Identity Manager Exchange Service.

3 Navigate to the services that are running on your server and start the **IDMExchangeOnline** service.
Uninstalling the Driver and Identity Manager Exchange Service

1. Navigate to the directory where the uninstaller is located.
2. Run the following depending on your platform from `/root/IDMAzureDriver/Uninstall` or `C:\Novell\IDMAzureDriver\Uninstall`:
   - **Linux**: `./uninstall`
   - **Windows**: `uninstall.exe`
3. On the **Uninstall Options** page, uninstall the required components based on your requirement:
   - **Complete Uninstall**: Uninstalls the driver and the Identity Manager Exchange Service.
   - **Uninstall Specific Features**: Provides an option to uninstall the driver or Identity Manager Exchange Service individually.
4. Click **Next** and then click **Done**.
Creating a New Driver Object

You install the Azure AD driver files on the server where you want to run the driver, and then proceed to create the driver in the Identity Vault. You create the Azure AD driver by installing the driver packages or importing the basic driver configuration file and then modifying the driver configuration to suit your environment.

Creating the Driver Object in Designer

An administrator must use Designer to create the Azure AD driver.

The Azure AD driver is package-enabled and you must install and deploy the driver using Designer. You can use iManager to view and edit the deployed configuration. NetIQ recommends that you use Designer to perform any changes.

Importing the Driver Packages

The driver packages contain the items required to create a driver, such as policies, entitlements, and filters. These packages are only available in Designer and can be updated after they are installed. You should use the most current version of the packages in the Package Catalog before you can create a new driver object.

1. Open Designer.
2. In the toolbar, click Help > Check for Package Updates.
3. Click OK to update the packages or click OK if the packages are up-to-date.
4. Right-click Package Catalog and then select Import Package.
5. Select any Azure AD driver packages.
   or
   Click Select All to import all of the packages displayed.
6. Click OK to import the selected packages, then click OK in the successfully imported package message.

After the packages are imported, continue with Installing the Driver Packages.

Installing the Driver Packages

After you have imported the current driver packages into the Package Catalog, you can install the driver packages to create a new driver.

1. Open your project in Designer.
2. In the Modeler, right-click the driver set where you want to create the driver, then select New > Driver.
   Alternatively, you can drag and drop the Azure AD driver icon from the Cloud section of the Designer palette.
3 In the **Driver Configuration** wizard, select the **Azure AD Base** package from the list of base packages, then click **Next**.

4 Select the optional features to install for the Azure AD driver. All options are selected by default. The options are:
   - **Default Configuration**: This package contains the default configuration information for the driver. Always leave this option selected.

   **NOTE:** The **Azure AD Default** package and **Azure AD Exchange Default** package are included in **Default Configuration** package. By default, the **Azure AD Exchange Default** package is not selected. Select this package if you plan to use the Identity Manager Exchange Service.

   - **Entitlements and License Support**: This package contains configuration information and policies for synchronizing user accounts, group membership, roles and licenses. If you want to enable account creation and auditing through entitlements, verify that this option is selected.

      To enable the hybrid mode, select the **Azure AD Hybrid Entitlements** package. In this mode, the driver supports only Roles and License entitlements.

   - **Password Synchronization**: This package contains the policies that enables the driver to synchronize passwords. If you want to synchronize passwords, ensure that this package is selected.

   - **Account Tracking**: This package contains the policies that enable you to track accounts for reports. If you are using the Identity Reporting Module, ensure that this package is selected.

   - **Data Collection**: This package contains the policies that enables the driver to collect data for reports. If you are using the Identity Manager Reporting Module, ensure that this package is selected.

5 Click **Next**.

6 (Conditional) If there are package dependencies for the packages you selected to install, you must install them to install the selected package. Click **OK** to install the package dependencies listed.

7 (Conditional) If more than one type of package dependency must be installed, you are presented with these packages separately. Click **OK** to install any additional package dependencies.

8 On the **Driver Information** page, specify a name for the driver, then click **Next**.

9 On the **Driver Configuration** page, fill in the following fields to configure the driver:

   - **Authentication ID**: Provide the authentication information while configuring the domain connections for the driver. This is a qualified userprincipalname on Azure AD with login permissions. For example, admin@domain.onmicrosoft.com

   - **Password**: Specify the password for the driver to authenticate to Azure AD.

   - **Driver Options**: To view the driver options, select **Show**.

   - **Client ID**: Specify the account name which the driver will use to access the Azure AD applications.

   - **Client Secret**: Specify the password for the Client ID to access the Azure AD applications.

   **NOTE:** You created Client ID and Client Secret while creating a proxy application in Azure AD. For more information, see “Creating a Proxy Application on Azure AD” on page 18.

   - **Show Schema Extensions Configuration**: To show the schema extensions configuration options for the application (Azure AD), select **Show**.
Enable Hybrid Operation Mode: In hybrid mode, the driver provisions only roles and licenses while the users and groups are provisioned by the AD driver. By default, the parameter is set to Yes. If you want to run the driver in normal mode, set the option to No.

Activate Azure Directory Roles: By default, the driver obtains the roles that have been pre-activated in Azure Directory. If you want the driver to activate all Azure Directory roles, set this option to Yes. This fetches all the activated roles in Catalog Administrator. These roles are also available at the driver startup. Roles activation is one time activity and need not be performed again.

To obtain only pre-activated roles, leave the setting unchanged.

Existing Schema Extensions: To retain the previously-loaded configuration from Azure AD, select Preserve. To remove existing configuration, specify Remove.

Add a schema extension: Specify appropriate configuration details while adding a schema extension. You can add multiple schema extensions if required.

- **Name of extension:** Specify the name of the schema extension.
  
  If you create multiple schema extensions with the same name, the driver uses the first extension in the list and ignores the remaining extensions that have the same name.

- **Type of extension:** Specify the data type for the configured schema extension. Ensure that the data type is a supported schema extension type in Azure AD.

- **Target objects of extension:** Lists the target objects for the schema extension. A schema extension can be extended to multiple target object classes. For example, if you have a schema extension called Title, it can be extended to a User and Group object classes.

**NOTE:** You can configure a maximum of hundred extensions on Azure AD.

Subscriber Options: To view the Subscriber options, select Show.

Truststore file: Specify the name and path of the truststore file containing the trusted certificates used when a remote server is configured to provide server authentication. This file will contain certificates for Azure Graph and Exchange Service. For example, c:\security\truststore.

Proxy Host and Port: When an HTTP proxy is used, specify the host address and the host port. For example, 192.10.1.3:18180. Otherwise, leave the field blank.

Exchange and Powershell Service: When Identity Manager Exchange Service is enabled, the driver synchronizes Exchange users and groups using this service.

Exchange Service URL: Specify the URL of the Identity Manager Exchange Service.

For example, https://<ip-addr>:<port>/ExchServer.

Office 365 Exchange Online: To initiate a connection with Exchange Online and synchronize Office 365 exchange users and groups, select Yes.

Queue Operations: To enable queuing of objects when synchronizing between Azure AD and Identity Manager Exchange Service, select True.

Page Size: Set a value for the number of results displayed per page during Exchange Publisher poll.

Trace location: Specify the custom path where you want to save the Identity Manager Exchange Service logs. By default, the logs will be saved in this component’s installation directory.

Trace Level: Set the trace level for the Identity Manager Exchange Service.
Creating a New Driver Object

The driver supports five trace levels: NOTIFY, INFO, ERROR, MORE INFO, and DEBUG. The default trace level is NOTIFY. The next trace level, that is, INFO provides basic trace messages. ERROR provides some additional information than the previous level. Detailed messages are logged if you select INFO. DEBUG logs information on debugging data along with detailed messages.

**Trace File Size Limit:** Specify the trace file size limit in MB. The minimum value is 10 MB.

**Database Password:** Specify the database password. The driver uses this password to encrypt and connect to the Publisher cache. Ensure that the same password is used to reconnect to the cache at a later time.

**Publisher Options:** To view the Publisher options, select Show.

**Enable Publisher:** Allows you to enable or disable the Publisher connection for the driver.

**Publisher Polling Interval:** Specify a time period after which the driver should query Azure AD for new changes. The time is specified in minutes.

**Heart Beat Interval:** Allows the driver to send a periodic status message on the Publisher channel when there is no traffic for a specific duration. This indicates the time period at which the heart beat document is issued by the driver shim. The time is specified in minutes.

10 On the Remote Loader page, fill in the following fields to configure the driver to connect using the Remote Loader, then click Next:

- **Connect to Remote Loader:** By default, the driver is configured to connect using the Remote Loader. Click Next to continue. Otherwise, fill in the remaining fields to configure the driver to connect using the Remote Loader.
- **Host Name:** Specify the hostname or IP address of the server where the driver’s Remote Loader service is running.
- **Port:** Specify the port number where the Remote Loader is installed and running. The default port number is 8090.
- **KMO:** Specify the Key Name of the Key Material Object (KMO) that contains the keys and certificate the Remote Loader uses for an SSL connection. This parameter is only used when you use SSL for connections between the Remote Loader and the Identity Manager engine.
- **Other Parameters:** Specify any other parameters required to connect to the Remote Loader. Any parameters specified must use a key-value pair format, as follows: `paraName1=paraValue1 paraName2=paraValue2`
- **Remote Password:** Specify the Remote Loader’s password as defined on the Remote Loader. The Identity Manager server (or Remote Loader) requires this password to authenticate to the Remote Loader.
- **Driver Password:** Specify the driver object password that is defined in the Remote Loader service. The Remote Loader requires this password to authenticate to the Identity Manager server.

11 On the Azure AD Base page, fill in the following fields, then click Next:

- **Domain Name:** Specify the Azure AD domain site context. For example, `<domain name>.onmicrosoft.com or <domain name>.com` format.
- **Identities to be synchronized:** Specify whether the driver should synchronize identities from AD or configure the Identity Vault to act as the identity provider.

If you choose to configure the Identity Vault as an identity provider, association to any other directory is not required.
When you choose to synchronize identity from AD, you can synchronize only users that have an association with AD. If you are using the driver in hybrid mode, select only AD option. This enables the driver to synchronize the identities from the Identity Vault to AD from where the identities will be synchronized to Azure AD cloud through Azure AD Connect.

- **Usage Location**: Specify the two letter country code for the user availing the Office 365 services.

12 (Conditional) On the **Install Azure AD Managed System Information** page, fill in the following fields to define the ownership of Azure AD, then click **Next**:

**General Information**

- **Name**: Specify a descriptive name for the managed system.
- **Description**: Specify a brief description of the managed system.
- **Location**: Specify the physical location of the managed system.
- **Vendor**: Select the vendor of the managed system.
- **Version**: Specify the version of the managed system.

**System Ownership**

- **Business Owner**: Select a user object in the Identity Vault that is the business owner of Azure AD. This can only be a user object, not a role, group, or container.
- **Application Owner**: Select a user object in the Identity Vault that is the application owner of Azure AD. This can only be a user object, not a role, group, or container.

This page is only displayed if you selected to install the Data Collection packages and the Account Tracking packages.

**System Classification**

- **Classification**: Select the classification of Azure AD. This information is displayed in the reports. The options are as follows:
  - Mission-Critical
  - Vital
  - Not-Critical
  - Other

  If you select Other, you must specify a custom classification for Azure AD.

- **Environment**: Select the type of environment Azure AD provides. The options are as follows:
  - Development
  - Test
  - Staging
  - Production
  - Other

  If you select Other, you must specify a custom environment for Azure AD.

13 On the **Azure AD Password Synchronization** page, fill in the following fields, then click **Next**:

- **Set Password Never Expires**: If you set this option to True on the newly created users, the password does not expire for those users.
- **Disable Force Change Password at First Login**: If you set this option to True, a user is not prompted to change the password when the user logs in to Azure AD for the first time.
Set Strong Password Required: If you set this option to True, the user needs to set a strong password.

14 On the Account Tracking page, specify the name of the realm, security domain, or namespace in which the account name is unique. You must set the Realm to the Azure AD domain name.

15 On the Confirm Installation Tasks page, review the summary of tasks and click Finish.

The driver is now created. You can modify the configuration settings by Configuring the Driver.

Configuring the Driver

There are many settings that can help you customize and optimize the driver. The settings are divided into categories such as Driver Configuration, Engine Control Values, and Global Configuration Values (GCVs). Although it is important for you to understand all of the settings, your first priority should be to review the Driver Parameters located on the Driver Configuration page and the Global Configuration Values. These settings must be configured properly for the driver to start and function correctly. You can configure the driver with entitlements or with entitlements disabled.

To edit the properties, perform the following steps:

1 Open your project.
2 In the modeler, right-click the driver icon or the driver line, then select Properties.
3 Select Driver Configuration and configure the configuration properties.
4 Click GCVs > Entitlements and review the following settings:

   NOTE: These settings are only displayed if you installed the Entitlements package. If you selected the Azure AD Hybrid Entitlements package, only Roles and License entitlements are supported with this package.

   ▪ Use User Account Entitlement: Ensure the value of this parameter is set to true to enable the driver to manage user account permissions using the User Account entitlement. By default, the value is set to True.

   ▪ Use Group Entitlement: Ensure the value of this parameter is set to true to enable the driver to manage group memberships using the Group entitlement. By default, the value is set to True.

   IMPORTANT: If the values for Use User Account Entitlement and User Group Entitlement parameter is set to False, user and group membership synchronization is managed using the non-entitlement configuration method.

   ▪ Use License Entitlement: Ensure the value of this parameter is set to true to enable the driver to manage licenses using the License entitlement. By default, the value is set to True.

   ▪ Use Roles Entitlement: Ensure the value of this parameter is set to true to enable the driver to manage roles using the Roles entitlement. By default, the value is set to True.

5 Click Apply.
6 Modify any other settings as necessary.

   In addition to the driver settings, you should review the set of default policies and rules provided by the basic driver configuration. Although these policies and rules are suitable for synchronizing with Azure AD, your synchronization requirements for the driver might differ from the default policies. If this is the case, you require customization.

7 Click OK when finished.
8 Continue with “Deploying the Driver” on page 33.
Deploying the Driver

After a driver is created in Designer, it must be deployed into the Identity Vault.

1. In Designer, open your project.
2. In the Modeler, right-click the driver icon, then select Live > Deploy.
3. If you are authenticated to the Identity Vault, skip to Step 5; otherwise, specify the following information:
   - **Host**: Specify the IP address or DNS name of the server hosting the Identity Vault.
   - **Username**: Specify the DN of the user object used to authenticate to the Identity Vault.
   - **Password**: Specify the user’s password.
4. Click OK.
5. Read through the deployment summary, then click Deploy.
6. Click OK.
7. Click Define Security Equivalence to assign rights to the driver.
   - The driver requires rights to objects within the Identity Vault. The Admin user object is most often used to supply these rights. However, you might want to create a user account called DriversUser. Whatever rights that the driver needs to have on the server, the DriversUser object must have the same security rights.
   7a. Click Add, then browse to and select the object with the correct rights.
   7b. Click OK twice.
8. Click Exclude Administrative Roles to exclude users that should not be synchronized.
   - You should exclude any administrative User objects (for example, Admin and DriversUser) from synchronization.
   8a. Click Add, then browse to and select the user object you want to exclude.
   8b. Click OK.
   8c. Repeat Step 8a and Step 8b for each object you want to exclude.
   8d. Click OK.
9. Click OK.

Starting the Driver

When a driver is created, it is stopped by default. Identity Manager is an event-driven system and will start caching events as soon as the driver is deployed. These cached events will be processed once the driver is started.

To start the driver:

1. In Designer, open your project.
2. In the Modeler, right-click the driver icon, then select Live > Start Driver.
Activating the Driver

The Identity Manager driver for Office 365 and Azure AD is part of the Identity Manager Integration Module for Microsoft Enterprise.

This integration module requires a separate activation. After purchasing the integration module, you will receive activation details in your NetIQ Customer Center.

**IMPORTANT:** If you are using the driver with Identity Manager 4.5.5, ensure that you apply Identity Manager Integration Module for Microsoft Enterprise 4.6 activation key to activate the driver.

If you create the driver in a driver set that has not been previously activated with this integration module, the driver will run in the evaluation mode for 90 days. You must activate the driver with this integration module during the evaluation period; otherwise, the driver will be disabled.

If driver activation has expired, `ndstrace` displays an error message indicating that you need to reactivate the driver to use it. For information on activation, refer to Activating Identity Manager in the *NetIQ Identity Manager Setup Guide*. 
Upgrading an Existing Driver

The following sections provide information to help you upgrade an existing driver:

- “What’s New in Version 5.0.1?” on page 35
- “Upgrading the Driver” on page 35

What’s New in Version 5.0.1?

This version of the driver provides support for the following key features:

- The driver supports exchange role entitlement in both cloud-only and hybrid mode. Exchange roles are Office 365 Admin roles. You can use this entitlement to add or remove members from these roles. To use this entitlement, you must add a new package, Azure AD Exchange Role Entitlement, to the driver.

  NOTE: Before using this entitlement, ensure that the Exchange service is running.

- The driver supports group entitlement in hybrid mode. Azure Active Directory does not allow modifications on user and group objects that were synchronized from local Active Directory. The group entitlement support in hybrid mode enables you to manage membership for groups that are directly added in Azure AD cloud.

Upgrading the Driver

The driver upgrade process involves upgrading the installed driver packages and updating the driver files.

This section provides general instructions for updating a driver. For information about updating the driver to a specific version, search for that driver patch in the NetIQ Patch Finder Download Page and follow the instructions from the Readme file accompanying the driver patch release.

- “Upgrading the Installed Packages” on page 35
- “Applying the Driver Patch” on page 36

Upgrading the Installed Packages

1. Download the latest available packages.

   To configure Designer to automatically read the package updates when a new version of a package is available, click Windows > Preferences > NetIQ > Package Manager > Online Updates in Designer. However, if you need to add a custom package to the Package Catalog, you can import the package .jar file. For more information about creating custom packages, see Developing Packages in the NetIQ Designer for Identity Manager Administration Guide.
2 Upgrade the installed packages.
   2a Open the project containing the driver.
   2b Right-click the driver for which you want to upgrade an installed package, then click Driver > Properties.
   2c Click Packages.
       If there is a newer version of a package, there is check mark displayed in the Upgrades column.
   2d Click Select Operation for the package that indicates there is an upgrade available.
   2e From the drop-down list, click Upgrade.
   2f Select the version that you want to upgrade to, then click OK.

   **NOTE:** Designer lists all versions available for upgrade.

   2g Click Apply.
   2h (Conditional) Fill in the fields with appropriate information to upgrade the package, then click Next.
       Depending on which package you selected to upgrade, you must fill in the required information to upgrade the package.
   2i Read the summary of the packages that will be installed, then click Finish.
   2j Review the upgraded package, then click OK to close the Package Management page.

   For detailed information, see the Upgrading Installed Packages in the *NetIQ Designer for Identity Manager Administration Guide*.

### Applying the Driver Patch

The driver patch updates the driver files. You can install the patch as a root or non-root user.

- “Prerequisites” on page 36
- “Applying the Patch as a Root User” on page 37
- “Applying the Patch as a Non-Root User” on page 37

### Prerequisites

Before installing the patch, complete the following steps:

1. Take a back-up of the current driver configuration.
2. (Conditional) If the driver is running with the Identity Manager engine, stop the Identity Vault and the driver instance.
3. (Conditional) If the driver is running with a Remote Loader instance, stop the Remote Loader instance and the driver instance.
4. In a browser, navigate to the NetIQ Patch Finder Download Page.
5. Under Patches, click Search Patches.
6. Specify Identity Manager nn Azure AD Driver nn in the search box.
7. Download and unzip the contents of the patch file to a temporary location on your server.
   For example, IDM4.5_AzureAD_5010.zip.
Applying the Patch as a Root User

In a root installation, the driver patch installs the driver files RPMs in the default locations on Linux. On Windows, you need to manually copy the files to the default locations.

1. Ensure that you have completed the prerequisites for installing the patch. For more information, see “Prerequisites” on page 36.
2. On the server where you want run the patch, log in as root.
3. Depending on your platform, perform one of the following actions:
   - **Linux**: Run the following command in a terminal window:
     ```
     rpm -Uvh <Driver Patch File Temporary Location>/linux/netiq-DXMLRESTAzure.rpm
     ```
     For example, `rpm -Uvh <IDM4.5_AzureAD_5010.zip>/linux/netiq-DXMLRESTAzure.rpm`
   - **Windows**: Navigate to the `<Extracted Driver Patch File Temporary Location>`\windows folder and copy the AZDriverShim.jar file to your driver installation folder.
     For example, `<IdentityManager installation>\NDS\lib` or `<IdentityManager installation>\RemoteLoader\<architecture>\lib`.

4. (Conditional) Copy the Exchange Service files.
   This step is only required if you enabled the driver to synchronize Exchange data or if you want to use Active Directory PowerShell.
   4a. Stop the Identity Manager Exchange Online service from Windows Services Console (services.msc).
   4b. Navigate to the `<Extracted Driver Patch File Temporary Location>`\windows folder and copy the following files to your Exchange service installation folder:
      - ExchServerHost.exe
      - IDMExchServer.dll
      For example, `<IdentityManager installation>\ExchangeServerHost`.
   4c. Start the Identity Manager Exchange Online service from Windows Services Console (services.msc).

5. (Conditional) If the driver is running locally, start the Identity Vault and the driver instance.
6. (Conditional) If the driver is running with a Remote Loader instance, start the Remote Loader and the driver instance.

Applying the Patch as a Non-Root User

1. Verify that `<non-root eDirectory location>/rpm` directory exists and contains the file, _db.000.
   The _db.000 file is created during a non-root installation of the Identity Manager engine. Absence of this file might indicate that Identity Manager is not properly installed. Reinstall Identity Manager to correctly place the file in the directory.
2. To set the root directory to non-root eDirectory location, enter the following command in the command prompt:
   ```
   ROOTDIR=<non-root eDirectory location>
   ```
This will set the environmental variables to the directory where eDirectory is installed as a non-root user.

3 Download the patch and untar or unzip the downloaded file.

4 To install the driver files, run the following script in a command prompt:

```bash
#!/bin/sh
#set -x
#© 2017 NetIQ Corporation and its affiliates. All Rights Reserved

clear
echo "======================================================================
Installing packages..."
echo "======================================================================"
if [ "$1" == "" ]; then
  exit
fi
pkgfile=$1
ROOTDIR="/local/home/bshidm/base/bshappl/edir"
RPMDB=$ROOTDIR/rpm
if [ ! -d "$RPMDB" ]; then
  mkdir $RPMDB
fi
# create rpm database if it doesn't exist
if [ ! -f $RPMDB/__db.000 ]
then
  # mkdir -p $RPMDB
  rpm --dbpath "$RPMDB" --initdb
fi
RPM_FLAGS="--dbpath $RPMDB -Uvh --relocate=/etc=$ROOTDIR/etc --relocate=/opt=$ROOTDIR/opt --relocate=/opt/novell/eDirectory/lib64=$ROOTDIR/opt/novell/eDirectory/lib64 --relocate=/var=$ROOTDIR/var --badreloc --nodeps --replacefiles --force"
rpm $RPM_FLAGS $pkgfile
```
Securing Driver Communication

The driver communicates over SSL with Azure AD and Identity Manager Exchange Service.

**IMPORTANT:** The connection accepts certificates only from a Java keystore. Make sure that the keystore for the certificates is a Java keystore.

The following sections provide instructions for creating a secure connection:

- “Securing Communication with Azure AD Graph” on page 39
- “Securing Communication with Identity Manager Exchange Service” on page 39

### Securing Communication with Azure AD Graph

To set up SSL between the driver and Azure AD graph REST endpoints, perform the following steps:

1. Open the following URL from your browser:
   
   https://graph.windows.net

2. Obtain the public certificate and import it into the keystore.

   For example, if you are using Mozilla Firefox, perform the following steps:

   2a. In the address bar, click 
   
      ![icon](http://example.com/ssl_icon.png)
   
      and then click > next to graph.windows.net.

   2b. Click More Information.

   2c. In the Security tab of the Page Info window, click View Certificate.

   2d. In the Details tab, click Export and then click Save.

   2e. Add the exported key to the driver keystore using the following Java keytool command:

      You need to create a new keystore which will contain the public certificate of the Azure graph endpoint.

      ```
      keytool -import -file <path to the graph cert file>\<certname.crt> -keystore <mykeystore> -alias <aliasname>
      ```

### Securing Communication with Identity Manager Exchange Service

To set up SSL between the driver and Identity Manager Exchange Service, you need to create and import a server certificate into the root certificate store of the Windows server where the service is deployed. The following procedure assumes eDirectory as the Certificate Authority (CA).

1. Create a server certificate.

   1a. In iManager, log in to the connected eDirectory server with administrator rights.

   1b. Click Roles and Tasks > NetIQ Certificate Server > Create Server Certificate.

   1c. Select the server and provide a nickname for the certificate.
The nickname is same that you specified for Certificate Alias while installing Identity Manager Exchange Service. For more information see Step 6 on page 23.

1d Click Next, then click Finish to complete the certificate creation.

2 Import the server certificate from the connected eDirectory server and save it to a file in the .pfx format.
   2a In iManager, log in to the connected eDirectory server with administrator rights.
   2b Click Roles and Tasks > NetIQ Certificate Access > Server Certificates, then select any server certificate.
   2c Click Export.
   2d Select the certificate by nickname and select Export Private Key.
   2e Enter the password and click Next.
   2f To save the certificate to a file, click Save the exported certificate.

3 Import the certificate to the trusted store of the Windows server on which you will run Identity Manager Exchange Service.
   3a Copy the .pfx file to the Windows server.
   3b Click Start > Run > mmc.
   3c Click File > Add/Remove Snap-in.
   3d Select Certificates and click Add to import this snap-in by choosing Computer account.
   3e Click Finish.
   3f Navigate to Certificates > Trusted Root Certification Authorities.
   3g Right-click and then select All Tasks > Import.
   3h On the Welcome to the Certificate Import Wizard page, click Next.
   3i Click Browse and select the eDirectory certificate you exported in Step 2.
   3j Specify the password and click Next.
   3k Click Finish to import the certificate into the trust store.

4 Start Identity Manager Exchange Service. For more information, see “Verifying and Starting the Identity Manager Exchange Service” on page 24.

5 Open the following Exchange service URL from your browser:
   https://<Exchange_Service>:Port/ExchServer

6 Obtain the public certificate and import it into the same keystore which was created for the Azure graph endpoint.
   For example, perform the following steps to obtain a public certificate on Google Chrome:
   6a Click from the address bar and then click Details.
   6b In the Security tab, click View Certificate.
   6c In the Details tab, click Copy to File.
   6d In the Certificate Import Wizard, click Next.
   6e Select DER encoded binary and click Next.
   6f Click Browse and navigate to the directory where you want to save the certificate.
   6g Specify a name for the certificate and click Next.
   6h Click Finish to complete the export.
Add the exported key to the driver keystore by using the following Java keytool command:

```
keytool -import -file <path to the exchange cert file>\<certname.cer> -keystore <mykeystore> -alias <aliasname>
```
Transitioning from Existing Office 365 Driver to New Azure AD Driver

The Identity Manager driver for Office 365 and Azure Active Directory introduces significant architectural changes over the existing Office 365 driver. The driver provides the same and more functionality through an improved design that is more efficient and easier to configure. To learn more about the new architecture, see “Understanding How the Driver Works” on page 11.

Given these changes, in order to use the new driver, you need to migrate users and groups from Office 365 to Azure AD. The following sections help you accomplish this:

- “Preparing for Migrating Identities from Azure AD to Identity Vault” on page 43
- “Migrating Identities” on page 43
- “Transitioning Assignments Through User Application” on page 44

Preparing for Migrating Identities from Azure AD to Identity Vault

NetIQ recommends that you perform the migration in a test environment similar to your production environment before upgrading the production systems.

Before you begin, ensure that the following prerequisites are met:

- Turn off Exchange service and entitlements before starting the migration.
- Ensure that there is a valid matching attribute for user and group objects in the Identity Vault. You need to create a matching policy that includes a matching attribute so that you can do a one-to-one mapping. When a match is found, an association is created. For example, the `cn` attribute for a user in the Identity Vault is mapped to `UserPrincipalname` attribute in Azure AD. Similarly, the `cn` attribute for a group in Identity Vault is mapped to `displayName` attribute in Azure AD.

Migrating Identities

This process involves migration of all users and groups from Azure AD into the Identity Vault.

1. In iManager, click Identity Manager > Identity Manager Overview.
2. Browse to and select the driver set.
3. Click the Azure AD driver icon.
4. In the Identity Manager Driver Overview page, select Migrate and then Migrate into Identity Vault.

**NOTE:** You cannot perform a wildcard search to query users and groups for migration. You must select the user or group class to migrate.

5. In the Edit List window, select User class and click OK.

Similarly, to migrate Azure AD groups, select Groups class and click OK.
Transitioning from Existing Office 365 Driver to New Azure AD Driver

This process will also update the association for the migrated objects.

**Transitioning Assignments Through User Application**

As there are significant architectural changes between the existing Office 365 driver and the Azure AD driver, you need to recreate the existing Office 365 resources in the Azure AD driver. The following considerations apply while transitioning the existing Office 365 assignments to the Azure AD driver:

**Recreate the Office 365 driver resources for the Azure AD driver**

You can use the existing Office 365 resources as a reference to create the resources manually and then map them appropriately to the existing Office 365 roles. For example, you have an existing role in Catalog Administrator called IT_Admin_O365_Role and the role is mapped to O365_MailboxAdmin, O365_SecurityAdmin, and O365_SharePointServiceAdmin resources. To transition the role assignments from existing Office 365 driver to Azure AD driver, you need to create similar resources for the Azure AD driver and then map them appropriately to existing IT_Admin_O365_Role role. For more information about creating roles and resources, see Managing Roles and Resources in the NetIQ Identity Manager - User’s Guide to the Identity Applications.

The following procedure explains how to create a new resource in Azure AD, assign an entitlement value to the resource, and map the resource to an existing Office 365 role in Catalog Administrator:

1. Turn on entitlements for the Azure AD driver.
2. Create a new resource.
   - Open a Web browser and log in to Catalog Administrator. For example: http://myappserver:8180/rra
3. Click the Resources tab, then click New Resource.
4. Fill in the values to create a new resource with entitlement for the Azure AD driver.
5. In Entitlement or Driver list, expand the driver and select Role Entitlement.
6. Refresh the selected entitlement.
7. In Entitlement Value Information, select Mailbox Administrator, then click Apply.
8. Specify a name and description for the resource. For example, Azure_MailboxAdmin
   You must also create resources for other roles. For example, Security Admin, and SharePointService Admin
9. To assign the newly created Azure AD driver resources to an existing Office 365 role, go to the Roles tab and select the role from the list of roles. For example, IT_Admin_O365_Role
10. In the Mapped Resources section, search for the newly created Azure AD driver resources. You can type in part of a driver name to display a list of resources that meet the criteria or select it from the list of available resources.
11. Select Resources to associate to the role and click Add.
12. Enter a mapping description for the resource you selected.
13. Click Apply and Close to exit the Roles Administration page.

**Manually assign permissions on the newly created resources**

If you have resources with direct assignments (resources not mapped to any role), then manually assign the permissions appropriately on the newly created resources for the Azure AD driver in Catalog Administrator.
Understanding Identity Manager Exchange Service

Identity Manager Exchange Service is a REST-based Windows service to support Exchange Online. The Azure AD driver leverages this service to provision or deprovision user mailboxes, mail users, create or remove distribution lists and security groups on Office 365 Exchange Online. This service converts the driver REST calls to Exchange Online cmdlets to manage Exchange Online.

When the Azure AD driver starts, it initializes the service by sending information to Office 365 such as exchange domain, user name, and password. The Azure AD driver is properly initialized only if the system time is synchronized between the servers running the driver and the Exchange Online service.

The schema has been extended to include the following attributes to support Office 365 Exchange Online:

- **DirXML-AADObjectType**: Contains the type for a user or a group object.
  
<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>UserMailbox</td>
<td>Creates a mailbox user in Exchange Online</td>
</tr>
<tr>
<td>MailUser</td>
<td>Creates a mail user in Exchange Online</td>
</tr>
<tr>
<td>Distribution</td>
<td>Creates a distribution group in Exchange Online</td>
</tr>
<tr>
<td>Security</td>
<td>Creates a security group in Exchange Online</td>
</tr>
</tbody>
</table>

For example, to add a mail user, set the **DirXML-AADObjectType** attribute to **MailUser**. To create an Exchange group, set this attribute to **Distribution** or **Security**.

- **DirXML-AADArchiveStatus**: Contains the mailbox archive status for an Exchange Online user.

- **DirXML-AADLitigationHoldEnabled**: Contains the mailbox litigation hold status for an Exchange Online user.

- **DirXML-AADLegacyExchangeDN**: Contains the Exchange server DN for a mailbox.

If you are not using Exchange Online, these attributes are not required.

The service also supports execution of PowerShell cmdlets that are part of XDS as values of **PSEExecute** attribute.

PowerShell is a shell-based automation framework created by Microsoft that allows users to manage the internal functions of other Microsoft products, including Active Directory and Exchange. PowerShell uses special .NET classes called cmdlets to perform various processing actions on objects in your Active Directory or Exchange environments. Identity Manager can use PowerShell cmdlets to perform post-processing on events by sending the cmdlets to the Azure AD driver using policies.

For example:
NOTE: For PowerShell reference, use lowercase format. For example, psexecute.

For more information about PowerShell, see the following resources:

Refer to the following sections if you are experiencing a problem with the Azure AD driver.

- “Synchronizing country and usageLocation Attributes” on page 47
- “Azure AD Password Complexity” on page 48
- “Restoring the Driver to Current State” on page 48
- “No Trusted Certificate Found Exception” on page 48
- “Exchange Error During Driver Restart” on page 48
- “Setting the set-executionPolicy to RemoteSigned in the Powershell” on page 49
- “Email Address is Set Incorrectly for Groups that are Provisioned to a Different Valid Domain” on page 49
- “Revoking Roles and Licenses in Hybrid Mode” on page 49
- “Setting Primary SMTP Address With EmailAddress Attribute Displays An Error” on page 49
- “Issue with the Size of PowerShell Log File” on page 49
- “License Dependency in Developer Pack” on page 50
- “User Name Cannot Contain Some Special Characters” on page 50
- “Restoring a Mailbox or Mail User Displays a Warning Message” on page 50
- “Random Errors While Connecting to the Exchange Portal” on page 50
- “Adding a Graph User to Group Fails” on page 51
- “No Trusted Certificate Found Exception” on page 51
- “Driver Fails to Connect to Microsoft Graph API Due to Invalid Certificate Error” on page 51

Synchronizing country and usageLocation Attributes

You can set the following attributes while using eDirectory to select a country for a user:

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>C</td>
<td>Mapped with usageLocation attribute of Azure AD. It contains a two-character country code as defined by the ISO.</td>
</tr>
<tr>
<td>co</td>
<td>Mapped with country attribute of Azure AD. It contains a longer name for the country.</td>
</tr>
</tbody>
</table>

Since the ISO-defined character country codes are intended to be used by the Azure AD licenses, the default schema in the Identity Vault includes co and C attributes.
Azure AD Password Complexity

Passwords must adhere to the Azure AD password requirements. A user cannot be added if the specified password does not meet these requirements.

Complexities and requirements in Azure AD password policies are different from complexities and requirements in eDirectory. If you plan to use password synchronization, create and use passwords that match the rules of complexity in both Azure AD and eDirectory.

For information about Azure AD password complexity requirements, see “Password must meet complexity requirements”.

For information about managing passwords in eDirectory, see the Password Management Administration Guide.

**TIP:** Make the password policies for both Identity Vault and Azure AD similar to each other as you can. In a lab environment, disable strong-password functionality on Azure AD before installing the Azure AD driver. After the driver is working properly, make sure that passwords used in eDirectory and Azure AD satisfy the rules of complexity for both systems. Then re-enable strong-password functionality on Azure AD.

Restoring the Driver to Current State

If you need to reset the Publisher state of the driver to prevent the driver from picking up interim events and performing unwanted actions on the Identity Vault, perform the following steps after stopping the driver.

1. Delete the Dirxml-DriverStorage attribute on the driver object in the Identity Vault.
2. If the driver is remotely loaded, delete the state file from the Remote Loader server.
3. Set the driver to Manual or Automatic startup.
4. Start the driver.

No Trusted Certificate Found Exception

This issue occurs when the certificate is changed at the Azure Graph endpoint.

To workaround this issue, import the new public certificate into the trust store of the driver. For more information, see “Securing Communication with Azure AD Graph” on page 39.

Exchange Error During Driver Restart

Except the case of invalid credentials, when the driver fails to connect to MSOL, the driver makes three attempts to connect to MSOL with an interval of 30 seconds after each attempt.

If the driver fails to connect to MSOL after three attempts, the driver shuts down.
Setting the set-executionPolicy to RemoteSigned in the Powershell

The `set-ExecutionPolicy` cmdlet enables you to determine the PowerShell scripts that can be run on your computer.

By default, `set-ExecutionPolicy` is set to `Restricted`. To start the driver, change the setting to `RemoteSigned` in PowerShell. Otherwise, the driver fails to start and displays an error message.

Email Address is Set Incorrectly for Groups that are Provisioned to a Different Valid Domain

When you configure the driver to a different valid domain and add an exchange group on the Subscriber channel, the email address is set incorrectly for the group on the exchange portal.

Workaround: Add `PrimarySmtpAddress` to the driver filter and add `PrimarySmtpAddress` for the group on the Subscriber channel.

Revoking Roles and Licenses in Hybrid Mode

When the Azure AD driver is running in a hybrid mode and a user’s account permission is revoked using the AD driver, the account is either disabled or deleted in AD and the corresponding association is removed from the Identity Vault. This action also triggers AAD Connect to disable or delete the user from Azure AD. However, this action does not revoke user’s Roles and License assignments in the User Application.

Workaround: Manually remove the Roles and License assignments for the user from the User Application.

Setting Primary SMTP Address With EmailAddress Attribute Displays An Error

When you set the primary SMTP address from `EmailAddress` attribute, an error message is displayed.

Workaround: To synchronize the primary SMTP address, create a custom attribute in eDirectory and map it with the `PrimarySmtpAddress` attribute.

Issue with the Size of PowerShell Log File

By default, the PowerShell log file is located at `\AppData\Local\Microsoft\Office365\Powershell`. When you execute `MSOnline` cmdlets in the Exchange service, the log file increases in size.

Workaround: To prevent the logs from getting included in the file, restrict the rights to the directory containing the log file.
License Dependency in Developer Pack

The Office 365 portal does not allow you to revoke an individual license if it has a dependency on other licenses. For example, an individual license is dynamically allocated to a resource in the User Application.

To workaround this issue, remove the dependent licenses before attempting to revoke the individual license. For example, if Office Online for Developer license is dependent on SharePoint Online for Developer license, you need to revoke Office Online for Developer license before you revoke SharePoint Online for Developer license.

User Name Cannot Contain Some Special Characters

While adding a user, if the user name includes some special characters that Azure AD does not support in userprincipalname, the user addition fails with an error. For details about the characters that are not supported, see the Microsoft web site.

You can customize your policies to remove the unsupported characters from the attributes.

Restoring a Mailbox or Mail User Displays a Warning Message

When you restore a mailbox or mail user, the following message is displayed:

Operation Failed: Get-User: The operation couldn't be performed because object couldn't be found

This issue does not cause any functionality loss. You can ignore the message and continue with restoring the mailbox or mail user.

Random Errors While Connecting to the Exchange Portal

You might encounter the following errors while connecting to the Exchange portal:

Driver fails to connect to the Exchange portal

The driver shuts down with the following error message.

There was no endpoint listening that could accept the message.

This issue is observed when the Exchange portal is down.

Workaround: Start the driver when the Exchange portal is functional.

Driver stops with a fatal error

In iManager, when you modify any driver parameter and try to restart the driver, the driver shuts down with the following error message:

IOException: graph.windows.net: Name or service not known

Workaround: Start the driver when the Exchange portal is functional.
Azure AD Cloud reports java.net.UnknownHostException: login.windows.net error

This issue is randomly observed.

If you restart the driver, the driver displays the following error, when the Office 365 Exchange Online parameter is set to No and Publisher channel is disabled.

java.net.UnknownHostException: login.windows.net

This error is reported from Azure AD. As there is no functionality loss, start the driver after few minutes.

Random Error Messages in Exchange Trace

When you run the driver with Exchange Online enabled, error messages are reported in the Exchange trace. For example:

publish: Operation Failed: Starting a command on the remote server failed with the following error message. The I/O operation has been aborted because of either a thread exit or an application request

Ignore the error message as it does not cause any functionality loss.

Adding a Graph User to Group Fails

This issue is randomly observed.

To workaround this issue, delete the DirXML-ApplicationSchema attribute and restart the driver.

No Trusted Certificate Found Exception

A client certificate needs to be added to the driver’s Java keystore. For more information, see “Securing Communication with Identity Manager Exchange Service” on page 39.

Driver Fails to Connect to Microsoft Graph API Due to Invalid Certificate Error

Most Azure services get their SSL/TLS certificates from a known set of intermediate certificate authorities (CAs) that Microsoft operates. Microsoft publishes details of these CAs in its Certificate Practice Statement (CPS). The following CA’s have been recently introduced:

- Microsoft IT TLS CA 1
- Microsoft IT TLS CA 2
- Microsoft IT TLS CA 4
- Microsoft IT TLS CA 5

You must include the new CAs in the driver’s truststore file. Otherwise, the driver reports an invalid certificate exception in the trace.

To workaround this issue, perform the steps described in “Securing Communication with Azure AD Graph” on page 37. You must repeat the procedure for all the certificates generated by all the four CAs. After the certificates are imported into the truststore file, the Azure driver works properly.
The name of a certificate is specified by the 'Issued by' field of the certificate.

Microsoft keeps replacing the CAs that it uses to validate Microsoft Graph API (https://graph.windows.net/); therefore, you must refresh the browser every time the API is launched. In case a new certificate is available, you must download it.
Driver Properties

This section provides information about the Driver Configuration and Global Configuration Values properties for the Azure AD driver. These are the only unique properties for drivers. All other driver properties (Named Password, Engine Control Values, Log Level, and so forth) are common to all drivers.

The information is presented from the viewpoint of iManager. If a field is different in Designer, it is marked with a Designer icon.

- "Driver Configuration" on page 53
- "Global Configuration Values" on page 57

Driver Configuration

In iManager:

1. Click to display the Identity Manager Administration page.
2. Open the driver set that contains the driver whose properties you want to edit:
   2a. In the Administration list, click Identity Manager Overview.
   2b. Click the Driver Sets tab.
   2c. If the driver set is not listed on the Driver Sets tab, use the Search In field to search for and display the driver set.
   2d. Click the driver set to open the Driver Set Overview page.
3. Locate the driver icon, then click the upper right corner of the driver icon to display the Actions menu.
4. Click Edit properties to display the driver’s properties page.

   By default, the Driver Configuration page is displayed.

In Designer:

1. Open a project in the Modeler.
2. Right-click the driver line, then click Properties.
3. Click Driver Configuration.

The Driver Configuration options are divided into the following sections:

- “Driver Module” on page 54
- “Driver Object Password” on page 54
- “Authentication” on page 54
- “Startup Option” on page 55
- “Driver Parameters” on page 55
Driver Module

The driver module changes the driver from running locally to running remotely or the reverse.

Connect to Remote Loader: Used when the driver is connecting remotely to the connected system. The options are:

- **Java**: Specify the name of the Java class.
- **Native**: Specify the name of the DLL file. This option is not applicable to this driver.
- **Connect to Remote Loader**: Select this option to specify the remote loader client configuration.

Designer includes one sub-option:

- **Remote Loader client configuration for documentation**: Includes information on the Remote Loader client configuration when Designer generates documentation for the driver.

Driver Object Password

**Driver object password**: Use this option to set a password for the driver object. If you are using the Remote Loader, you must enter a password on this page or the remote driver does not run. This password is used by the Remote Loader to authenticate itself to the remote driver shim.

Authentication

The Authentication section stores the information required to authenticate to the connected system.

**Authentication ID**: Provide the authentication information while configuring the domain connections for the driver. This is a qualified userprincipalname on Azure AD with login permissions. For example, admin@domain.onmicrosoft.com

**Remote Loader connection parameters**: Used only if the driver is connecting to the application through the Remote Loader. The parameter to enter is `hostname=xxx.xxx.xxx.xxx port=xxxx kmo=certificatename`, when the hostname is the IP address of the application server running the Remote Loader server and the port is the port the Remote Loader is listening on. The default port for the Remote Loader is 8090.

The kmo entry is optional. It is only used when there is an SSL connection between the Remote Loader and the Identity Manager engine. For example, `hostname=10.0.0.1 port=8090 kmo=IDMCertificate`. Specify the additional parameters in the Other parameters field.

**Driver Cache Limit (kilobytes)**: Specify the maximum event cache file size (in KB). If it is set to zero, the file size is unlimited. select **Unlimited** option to set the file size to unlimited in Designer.

**Application Password**: Use the Set Password option to set the application authentication password.

**Remote Loader Authentication**: Used only if the driver is connecting to the application through the Remote Loader. The parameter to enter is `hostname=xxx.xxx.xxx.xxx port=xxxx kmo=certificatename`, when the hostname is the IP address of the application server running the Remote Loader server and the port is the port the Remote Loader is listening on. The default port for the Remote Loader is 8090.

The kmo entry is optional. It is only used when there is an SSL connection between the Remote Loader and the Identity Manager engine. For example, `hostname=10.0.0.1 port=8090 kmo=IDMCertificate`. Specify the additional parameters in the Other parameters field.
Remote loader password: Use this option to update the remote loader password.

Startup Option

The Startup Option section allows you to set the driver state when the Identity Manager server is started.

Auto start: The driver starts every time the Identity Manager server is started.

Manual: The driver does not start when the Identity Manager server is started. The driver must be started through Designer or iManager.

Disabled: The driver has a cache file that stores all of the events. When the driver is set to Disabled, this file is deleted and no new events are stored in the file until the driver state is changed to Manual or Auto Start.

If the driver is Disabled and then changed to Auto start or Manual, you can select the Do Not Automatically Synchronize the Driver check box. This prevents the driver from synchronizing objects automatically when it loads. To synchronize objects manually, use the Synchronize button on the Driver Overview page.

Driver Parameters

The Driver Parameters section lets you configure the driver-specific parameters. When you change driver parameters, you tune driver behavior to align with your network environment.

The driver setting parameters are divided into the following categories:

- “Driver Settings” on page 55
- “Driver Operation Mode” on page 55
- “Schema Extensions Configuration” on page 56
- “Subscriber Settings” on page 56
- “Publisher Settings” on page 57

Driver Settings

Client ID: Specifies the account name which the Azure AD driver will use to access the Azure AD applications. You need to set the level of permissions required by the driver.

Client Secret: Specifies the password for the client ID to access the Azure AD applications.

NOTE: For information on creating the Client ID and Client Secret for your application, see “Creating a Proxy Application on Azure AD” on page 18.

Remove Existing Passwords: Select this option to clear the existing password. You can enter a new password at this point.

Driver Operation Mode

Enable Hybrid Operation Mode: In hybrid mode, the driver supports only Roles and License entitlements. The users and groups are provisioned by the AD driver. By default, the parameter is set to Yes. If you want to run the driver in cloud-only mode, set the value to No and install the Azure AD Cloud Only Entitlements package.
Activate Azure Directory Roles: To activate the Azure AD roles, set this parameter to Yes. Azure AD driver will fetch only the roles that are already activated.

Schema Extensions Configuration

Show Schema Extensions Configuration: To show the schema extensions in the configuration wizard, select Show.

Existing Schema Extensions: To retain the previously-loaded configuration, select Preserve. However, when you select Preserve and add a new extension, the extension will be added. Select Remove to overwrite an existing configuration.

Add a schema extension: Add a schema extension and specify appropriate configuration details. You can add multiple schema extensions if required.

- **Name of extension**: Specify the name of the schema extension. If you create more than one schema extension with the same name, the first extension in the list will be used. The remaining extensions will be ignored.
- **Type of extension**: Indicates the data type for the configured schema extension. Ensure that the data type is a supported schema extension type in Azure AD.
- **Target objects of extension**: Lists the target objects for the schema extension. A schema extension can be extended to multiple target object classes. For example, if you have a schema extension called Title, it can be extended to a User and Group object class.

**NOTE:** You can configure a maximum of hundred extensions on Azure AD.

Subscriber Settings

**Domain Name**: Specify the Azure AD domain site context. For example, `<domain name>.onmicrosoft.com or <domain name>.com format.

**Truststore file**: Specify the name and path of the truststore file containing the trusted certificates used when a remote server is configured to provide server authentication. This file will contain certificates for Azure Graph and Exchange Service. For example, `c:\security\truststore`.

**Proxy Host and Port**: When an HTTP proxy is used, specify the host address and the host port. For example, 192.10.1.3:18180. Otherwise, leave the field blank.

**Set proxy authentication parameters**: To set proxy authentication, select Show and specify the user and password for proxy authentication.

**Exchange and Powershell Service**: When this service is enabled, the driver will synchronize Exchange users and groups using this service.

**Refresh Deleted User Cache**: When you set this parameter to Yes, the local cache that contains the deleted users is refreshed with the objects present in the Office 365 deleted user container.

**Office 365 Exchange Online**: To initiate a connection with Exchange Online and synchronize Office 365 exchange users and groups, select Yes.

**Queue Operations**: To enable queuing of objects when synchronizing between Azure AD and Identity Manager Exchange Service, select True.
**Page Size:** Set a value for the number of results per page during Exchange Publisher poll.

**Trace location:** Specify the custom path where you want to save the Identity Manager Exchange Service logs. By default, the logs will be saved in this component's installation directory.

**Trace Level:** Set the trace level for the Identity Manager Exchange Service. The driver supports five trace levels: NOTIFY, INFO, ERROR, MORE INFO, and DEBUG. The default trace level is NOTIFY. The next trace level, that is, INFO provides basic trace messages. ERROR provides some additional information than the previous level. Detailed messages are logged if you select INFO. DEBUG logs information on debugging data along with detailed messages.

**Trace File Size Limit:** Specify the trace file size limit. The value is measured in MB. The minimum value is 10 MB.

**Database Password:** Specify the database password. This password is used to encrypt and connect to the Publisher cache. Ensure that the same password is used to reconnect to the cache at a later time.

**Remove Existing Passwords:** Select this option to clear the existing password. You can enter a new password at this point.

**Publisher Settings**

**Enable publisher:** Allows you to enable or disable the Publisher connection for your Azure AD driver.

**Publisher Polling Interval:** Specify a time period after which Azure AD will be queried for new changes. The time is indicated in minutes.

**Heart Beat Interval:** Allows the driver to send a periodic status message on the Publisher channel when there has been no Publisher channel traffic for the given number of minutes. This indicates the time period at which the heart beat document is issued by the driver shim. The time is indicated in minutes.

**Global Configuration Values**

Global configuration values (GCVs) are values that can be used by the driver to control functionality. GCVs are defined on the driver or on the driver set. Driver set GCVs can be used by all drivers in the driver set. Driver GCVs can be used only by the driver on which they are defined.

The Azure AD driver includes several predefined GCVs. You can also add your own if you need additional ones as you implement policies in the driver.

To access the driver's GCVs in iManager:

1. Click to display the Identity Manager Administration page.
2. Open the driver set that contains the driver whose properties you want to edit:
   - In the Administration list, click Identity Manager Overview.
   - If the driver set is not listed on the Driver Sets tab, use the Search In field to search for and display the driver set.
   - Click the driver set to open the Driver Set Overview page.
3. Locate the Azure AD driver icon, click the upper right corner of the driver icon to display the Actions menu, then click Edit Properties.
To add a GCV to the driver set, click **Driver Set**, then click **Edit Driver Set properties**.

To access the driver’s GCVs in Designer:

1. Open a project in the Modeler.
2. Right-click the Azure AD driver icon or line, then select **Properties > Global Configuration Values**.

or

To add a GCV to the driver set, right-click the driver set icon , then click **Properties > GCVs**.

The global configuration values are organized as follows:

- “Password Synchronization” on page 58
- “Driver Configuration” on page 59
- “Account Tracking” on page 59
- “Exchange Role Entitlement” on page 60
- “Entitlements” on page 60
- “Managed System Information” on page 62

## Password Synchronization

These GCVs enable password synchronization between the Identity Vault and the Azure AD system.

In Designer, you must click the icon next to a GCV to edit it. This displays the Password Synchronization Options dialog box for a better view of the relationship between the different GCVs.

In iManager, you should edit the Password Management Options on the **Server Variables** tab rather than under the GCVs. The Server Variables page has a better view of the relationship between the different GCVs.

**Connected System or Driver Name:** Specify the name of the Azure AD system or the driver name. This value is used by the e-mail notification template to identify the source of the notification message.

**Application accepts passwords from Identity Manager:** If True, allows passwords to flow from the Identity Manager data store to the connected system.

**Identity Manager accepts passwords from application:** If True, allows passwords to flow from the connected system to Identity Manager.

**Publish passwords to NDS password:** If True, uses the password from the connected system to set the non-reversible NDS password in eDirectory.

**Publish passwords to Distribution Password:** If True, uses the password from the connected system to set the NMAS Distribution Password used for Identity Manager password synchronization.

**Require password policy validation before publishing passwords:** If True, applies NMAS password policies during publish password operations. The password is not written to the data store if it does not comply.

**Reset user’s external system password to the Identity Manager password on failure:** If True, on a publish Distribution Password failure, attempt to reset the password in the connected system by using the Distribution Password from the Identity Manager data store.
Notify the user of password synchronization failure via e-mail: If True, notify the user by e-mail of any password synchronization failures.

Driver Configuration

The following GCVs contain configuration information for the Azure AD driver. They are divided into the following categories:

Synchronization Settings

Use the following GCVs to control how the driver is configured:

Office 365 settings

- **Domain Name**: Specify the Office 365 site context using the `admincentral.onmicrosoft.com` format.
- **Identities to be synchronized**: Specify whether the driver should synchronize identities from AD or configure the Identity Vault to act as the identity provider.
  - If you choose to configure the Identity Vault as an identity provider, association to any other directory is not required.
  - When you choose to synchronize identity from AD, you can synchronize only users that have an association with AD. If you are using the driver in hybrid mode, select only AD option. This enables the driver to synchronize the identities from the Identity Vault to AD from where the identities will be synchronized to Azure AD cloud through Azure AD Connect.
- **Usage Location**: Specify the two letter country code of the user availing Office 365 services.
- **Enable Hybrid Operation Mode**: If Yes, the driver will provision only Roles and License entitlements while the users and groups are provisioned by the AD driver. To run the driver in normal mode, set the option to No.

Account Tracking

Account tracking is part of the Identity Reporting Module.

**Enable Account Tracking**: Set this to True to enable account tracking policies. Set it to False if you do not want to execute account tracking policies.

**Realm**: Specify the name of the realm, security domain, or namespace in which the account name is unique. You must set the Realm to the Office 365 Domain Name.

**Object Class**: Add the object class to track. Class names must be in the application namespace.

**Identifiers**: Add the account identifier attributes. Attribute names must be in the application namespace.

**Status attribute**: Specify the name of the attribute in the application namespace to represent the account status.

**Status active value**: Value of the status attribute that represents an active state.

**Status inactive value**: Value of the status attribute that represents an inactive state.
**Subscription Default Status**: Select the default status that the policies assume when an object is subscribed to the application and the status attribute is not set in the Identity Vault. The options are:

- Active
- Inactive
- Undefined
- Uninitialized

**Publication Default Status**: Select the default status that the policies assume when an object is published to the Identity Vault and the status attribute is not set in the application. The options are:

- Active
- Inactive
- Undefined
- Uninitialized

**Exchange Role Entitlement**

This entitlement is supported if you have upgraded to the 5.0.1 version of the driver. You need to import the **Azure AD Exchange Role Entitlement** package to use this entitlement.

**NOTE**: Before you use this entitlement, ensure that exchange service is running.

**Use Exchange Roles Entitlement**: Select **True** to enable the driver to manage exchange roles based on the driver's defined entitlements.

**Advanced Settings**: To enable the advanced settings such as data collection, role mapping, and resource mapping, select **Show**.

- **Allow data collection from exchange roles**: Select **Yes** if you want to allow data collection by the Data Collection Service for exchange roles.

- **Allow role mapping of exchange roles**: Select **Yes** if you want to allow mapping of exchange roles in Catalog Administrator.

- **Allow resource mapping of exchange roles**: Select **Yes** if you want to allow mapping of exchange roles in the Roles Based Provisioning Module.

- **Exchange Role extensions**: The content of this field is added below the entitlement elements in the EntitlementConfiguration resource object.

**Entitlements**

There are multiple sections in the **Entitlements** tab. Depending on which packages you installed, different options are enabled or displayed.

- “Entitlements” on page 61
- “Data Collection” on page 61
- “Role Mapping” on page 61
- “Resource Mapping” on page 62
- “Entitlement Extensions” on page 62
Entitlements

**Use User Account Entitlement:** Entitlements act like an On/Off switch to control account access. Enable the driver for entitlements to create accounts, and remove/disable it when the account entitlement is granted to or revoked from users. If you select *True*, user accounts in Azure AD can be controlled by using entitlements.

**NOTE:** User Account Entitlement is supported in cloud-only mode. It is not supported in hybrid mode.

- **Enable Login Disabled attribute sync:** Specify whether the driver syncs the changes made to the Login Disabled attribute in the Identity Vault even if the User Account entitlement is enabled.
- **When account entitlement revoked:** Select the desired action in the Azure AD database when a User Account entitlement is revoked from an Identity Vault user. The options are **Disable Account** or **Delete Account**.

**Use Group Membership Entitlement:** Select *True* to enable the driver to manage Azure AD group membership based on the driver's Group entitlement. Select *False* to disable management of group membership based on entitlement.

**Use License Entitlement:** Select *True* to enable the driver to manage licenses based on the driver's defined entitlements. To assign multiple Azure AD licenses, you must create multiple resources on user application. This is required because an Azure AD license entitlement can have only a single value.

**Use Roles Entitlement:** Select *True* to enable the driver to manage roles based on the driver's defined entitlements. Select *False* to disable management of role assignments for users based on the entitlements.

Data Collection

Data collection enables the Identity Report Module to gather information to generate reports.

**Enable data collection:** Select *Yes* to enable data collection for the driver through the Data Collection Service by the Managed System Gateway driver. If you are not going to run reports on data collected by this driver, select *No*.

**Allow data collection from user accounts:** Select *Yes* to allow data collection by the Data Collection Service for user accounts.

**Allow data collection from groups:** Select *Yes* to allow data collection by the Data Collection Service through the Managed System Gateway driver for groups.

**Allow data collection from licenses:** Select *Yes* to allow data collection by the Data Collection Service for licenses.

**Allow data collection from roles:** Select *Yes* to allow data collection by the Data Collection Service for roles.

Role Mapping

The Identity Manager Catalog Administrator allows you to map business roles with IT roles.

**Enable role mapping:** Select *Yes* to make this driver visible to Catalog Administrator.
Allow mapping of user accounts: Select Yes if you want to allow mapping of user accounts in the Catalog Administrator. An account is required before a role, profile, or license can be granted through Catalog Administrator.

Allow mapping of groups: Select Yes if you want to allow mapping of groups in Catalog Administrator.

Allow mapping of licenses: Select Yes if you want allow mapping of licenses in Catalog Administrator.

Allow mapping of licenses: Select Yes if you want to allow mapping of roles in Catalog Administrator.

Resource Mapping

The Roles Based Provisioning Module allows you to map resources to users.

Enable resource mapping: Select Yes to make this driver visible to the Roles Based Provisioning Module.

Allow mapping of user accounts: Select Yes if you want to allow mapping of user accounts in the Roles Based Provisioning Module. An account is required before a role, profile, or license can be granted.

Allow mapping of licenses: Select Yes if you want to allow mapping of licenses in the Roles Based Provisioning Module.

Allow mapping of Exchange mailboxes: Select Yes if you want to allow mapping of roles in the Roles Based Provisioning Module.

Entitlement Extensions

User account extensions: The content of this field is added below the entitlement elements in the EntitlementConfiguration resource object.

Group extensions: The content of this field is added below the entitlement elements in the EntitlementConfiguration resource object.

License extensions: The content of this field is added below the entitlement elements in the EntitlementConfiguration resource object.

Role extensions: The content of this field is added below the entitlement elements in the EntitlementConfiguration resource object.

Managed System Information

These settings help the Identity Reporting Module function to generate reports. There are different sections in the Managed System Information tab.

- “General Information” on page 63
- “System Ownership” on page 63
- “System Classification” on page 63
- “Connection and Miscellaneous Information” on page 63
General Information

Name: Specify a descriptive name for the managed system.
Description: Specify a brief description of the managed system.
Location: Specify the physical location of the managed system.
Vendor: Select Microsoft as the vendor of the managed system.
Version: Specify the version of the managed system.

System Ownership

Business Owner: Browse to and select the business owner in the Identity Vault for the connected application. You must select a user object, not a role, group, or container.
Application Owner: Browse to and select the application owner in the Identity Vault for the connected application. You must select a user object, not a role, group, or container.

System Classification

Classification: Select the classification of the connected application. This information is displayed in the reports. The options are:
- Mission-Critical
- Vital
- Not-Critical
- Other
  If you select Other, you must specify a custom classification for the connected application.
Environment: Select the type of environment the connected application provides. The options are:
- Development
- Test
- Staging
- Production
- Other
  If you select Other, you must specify a custom classification for the connected application.

Connection and Miscellaneous Information

Connection and miscellaneous information: This set of options is always set to hide, so that you do not make changes to these options. These options are system options that are necessary for reporting to work.
NetIQ Corporation strives to ensure that our products provide quality solutions for your enterprise software needs. The following issues are currently being researched. If you need further assistance with any issue, please contact Technical Support.

- When you modify the Office 365 user name or password and restart the Azure AD driver, there is an increase in the Exchange service memory.
- If you modify the description for a group on Identity Vault, the changes are reflected on Office 365 and Exchange portals, but not on Azure portal.
- Delete the group description for a group in the New Azure portal. Save the changes and refresh the page. The saved changes are not reflected. This behavior is not seen in the Classic Azure portal.
- If you delete security, distribution, or Office 365 groups from Office 365, the driver cannot restore these groups. Microsoft does not support restoring these groups. For more information, see the Microsoft documentation.
- User assignments to some exchange admin roles fail and displays the following error message:

  com.novell.nds.dirxml.driver.azure.exceptions.ChannelException: Add-RoleGroupMember

  This issue is observed because some exchange admin roles do not support direct user assignments.

**NOTE:** This issue is specific to 5.0.1 version of the driver.
